With this "bill of rights" understood by coach, trainer, doctor, and player, each must play his part in coordinating the measures required to minimize the injuries. In contact sports the teaching of special techniques and the timing in coordinated team play are factors often not understood by the casual observer. It requires long hours of practice to develop timing in a team, and this is practice in live scrimmage. The doctor and trainer must be trained to observe and detect a "limping" or a "groggy" player from some yards distance. Continued play on a minor sprained ankle can aggravate a grade 1 lesion and often may result in an unnecessarily prolonged disability period. Each day of disability is a day lost not only in the player's development but also in the squad or team development. From our experience recurrent sprains can be controlled by protective adhesive strapping daily, plus a progressive resistance exercise program to the muscles in and about that joint. This is essentially controlled under the direction of doctor and trainer for the benefit of the player.

Preseason conditioning exercise to develop muscle tone on schedule is absolutely necessary. Within the last few months Professor Emeritus McCloy of the State University of Iowa has prepared and published a program for the National Federation of High School Athletic Associations which has been distributed to the members of this association. The exercise program is clearly defined and illustrated and can be followed by each preseason candidate at home. This is a great step forward, and if carried out in our high schools and colleges should have a significant influence on the early season injury incidence. Not only sprains but muscle or tendon strains are the bugbear of coaches and doctors in early season practice. Such can be prevented by the players returning for the first session of practice preconditioned.

Table 2.—*Total Contestants and Total Injuries as Related to Total Exposures**

Sport	No. Out†	No. of Exposures‡	No. of Injuries
Fall	3,840	3,741,477	2,170
Winter	4,268	13,989,276	470
Spring	6,267	18,320,132	813
All	14,375	36,050,885	3,453

*Exclusive of intramural teams, fall, 1936-spring, 1954, inclusive; and excluding the years, fall, 1942-spring, 1946, for which complete figures are unavailable. Since 1947-1948 the varsity and junior varsity football figures have been averaged. Data from Thorndike,[1] p. 66.

†The figure in the "No. Out" column represents the average of men out in each sport each day.

‡An "exposure" is taken to mean one afternoon period of practice or play for each man in each sport.

Another item that contributes to injury incidence is the player's apathetic attitude toward proper adjustment of pads. It is not uncommon to find football players who neglect to tighten or lace their shoulder pads or underarm elastic webbing straps. Furthermore, many of us have seen hip pads worn that are inadequate protection in order that the player in his own thinking might gain running speed. The proper wearing of protective equipment is the responsibility of coach, trainer, doctor, and player.

In the wide expanse of playing fields at Harvard, during the fall season, my staff consists of four surgeons and four trainers on the fields when contact sports are taking place. Through the week, one additional surgeon is in the field house clinic each afternoon and on Saturday one surgeon with each competing team other than with varsity football.

In order that the incidence of injury in organized athletics may be better known, it behooves those of us working with athletic trauma to report our results on a wide-scale basis. What is the true incidence in football, at the college level or at the high school level? Before one can determine such, one must have accurate records of diagnosis and period of disability of each injury on each college or high school squad, and until such a record is obtainable from the colleges and schools one hesitates to even hazard a guess. One fact is certain; namely, this incidence is too high, and the disability period in most instances is too long. From the coaches' point of view every day lost from practice not only hurts the player and his normal development in newly learned techniques but also hinders the whole squad's development.

In the past, several groups of interested associations have tried by questionnaires to obtain information on the incidence of injuries in sport, but the replies received were so few that the attempt at recording was abandoned. A recent study of this situation concerned all trauma on college campuses undertaken by the American College Health Association and the National Safety Council over a two-year period.[3] The first year 11 colleges participated, the second year 9. The report did not separate purely athletic trauma from other types, so that it failed to reveal anything on the incidence of trauma from sports. The National Federation of High School Athletic Associations is now embarking on a new attempt. One may rightly inquire as to where such a collection of data should be centered. To my mind, either the National Collegiate Athletic Association and the National Federation of High School Athletic Associations or the National Safety Council and the American College Health Association should be the source of such an annual report.

But can all colleges or schools render an accurate report of all athletic injuries? To obtain the complete picture of athletic trauma and its true incidence, it must cover all sports which are in intercollegiate and interscholastic competition. The records analyzed should be medical in origin and include at least an accurate medical diagnosis and the disability time lost from the squad season. With this material available from a good sample of schools and colleges, one can then draw significant conclusions. It can be undertaken regionally or nationally. Let us make a start toward accurately determining the true incidence of athletic trauma.

What measures can be taken to lessen the incidence of injury? Development of the rules of the sport, and the enforcement of these rules by the officials, is one item that has altered the incidence of injury. The protective equipment (padding) and its design is another. Just now we are looking for a better football helmet, and we think we have it, but the manufacturer can supply it in only one size. The design and construction of some pads afford little if any protection to the wearer. New materials are being tried in the fabrication of pads that have been inadequately tested in the laboratory and on the field. The third item, proved to reduce recurrent ligament sprains, is proper protective adhesive strapping for every practice or game. It matters significantly whether ligaments had been sprained in high school prior to entrance to college, and in such instances they receive daily strapping from the start of the season.

The purely medical prerogative is the diagnosis, treatment, and prognosis of all individual injuries once sustained. In addition, the prerogative pertaining to the prevention or aggravation of minor injury belongs to the medical staff. No one can deny that progress has been made in reducing the days of disability from athletic injuries. Table 3 demonstrates significantly the results of early, prompt treatment. Physicians, trainers, and coaches are all concerned with the individual player and his welfare. The permitting of a player with cerebral concussion to continue play should not be tolerated. Even the player who is exhausted physically and physiologically is more prone to injury if permitted to continue.

TABLE 3.—*Incidence of Sprains and Length of Disability Incurred in Sports at Harvard University*[*]

[*] From Thorndike, A.: J. A. M. A. 162:1126 (Nov. 17) 1956.

A player not mentally or physically capable of carrying out his assignments is of less value to a team than a fresh substitute. Every follower of body-contact sports can recall having seen some player allowed to continue in a rugged contest without full capacity of his mental processes. In the high school leagues, particularly, there is lack of adequate medical supervision of practice sessions of contact sports. The responsibility lies in the community schools' committees.

According to Eastwood's report[4] of the nine football fatalities in 1955 that were a direct result of competition, six were deaths of high school players. It is unfair to a coach not to provide him with adequate medical assistance. Even though the majority of injuries sustained are not serious, nobody can prophesy when a serious accident might occur.

The team physician must grasp the opportunity to determine whether a limping player should be taken out of competition. He should arrange with the team captain to call time out for any needed examination. He should be familiar with the functional testing of joints, the more common sites of fracture, and the simpler tests for diagnosis of type of injury. In instances of head injury, he should be alert and ask the player simple questions in order to determine whether there is amnesia with loss of orientation of time and place. If necessary the physician could call on the team captain to interrogate the injured player in order to determine whether the player knew his particular assignment in an individual play signal. When an arm or leg is involved, comparative tests of the normal side and the injured side are simple and practical.

TABLE 4.—*Types of Injuries Incurred Most Commonly in Sports at Harvard University**

* Data from Thorndike,[1] p. 66.
† From fall, 1943, until spring, 1946, sports were on a wartime basis, with organized sports continued only informally and on a limited basis.

Once the injury is located and diagnosed, its severity or degree is the important decision to make. Will continued play turn a sprain from grade 1 into grade 2 or grade 3? In many instances one cannot determine the degree of injury until 24 hours later. The player should be protected from an unnecessarily long disability period. There is no reason, from a pathological point of view, to think that an acutely sprained ligament can be supported by adhesive strapping, so that the player can be returned immediately to play without doing irreparable harm to the injured ligament. The torn ligament must heal, and one cannot put stress on it until the healing process is complete, and then only with daily supportive adhesive strapping. It will never again be as strong, since there will be fibrous scarring. The too early return to play of a player with a healing sprained ligament can undo good results of the partial healing process. The team physician must determine when the lesion has healed and the player is ready to return to play. He must realize that, if a player still limps, an ankle sprain is incompletely healed and that, regardless of the amount of adhesive tape applied, the player cannot yet withstand the stress of running and dodging.

The team physician must become familiar with the more common types of injuries produced in athletics and likewise the more commonly injured parts of the body. Tables 4 and 5 illustrate my own experience. Alertness on the part of the trainer and team physician and recognition of the more serious and less common injuries is a "must" in organized sports. In most body-contact sports, there is a time limit of three minutes in which the one responsible for diagnosis and prognosis must decide whether an injury is of sufficient degree to require the player to leave the field.

In view of the fact that many injuries in contact sports are recurrences of prior injuries, one must emphasize the importance of proper preventive measures to reduce the incidence of recurrent injuries. It should be noted that the use of procaine (Novocain) hydrochloride or some of its derivative with hydrocortisone and hyaluronidase has been known to cause complications. I wish to cite a case from the records of Dr. Carl Badgley, professor emeritus of orthopedic surgery, University of Michigan, Ann Arbor.

* From Thorndike,[1] p. 137.
† For seven academic years rather than five.

This 19-year-old college football player was first seen July 29, 1957, for painful swelling below the medial malleolus of his right foot. He was seen in consultation at the request of the boy's father. The doctors at the college had placed his leg in a plaster cast for one month four months previously; after removal of the cast there was considerable improvement in function of the leg, without pain. However, on resuming physical activity he had a recurrence of symptoms. Physical examination revealed ½ in. atrophy of the right calf and locally there was definite thickening of the tissues about the posterior tibialis tendon behind the malleolus; the functional testing of this muscle caused pain localized in this area. Anteroposterior, lateral, and mortise x-rays "failed to reveal any abnormality." In view of the fact that this patient had had multiple injections of procaine and hydrocortisone in this area, the diagnosis of chronic tenosynovitis was made and operation for release of the tendon sheath was recommended.

At operation on Aug. 2nd this diagnosis was confirmed, and crystalline deposits were found in the area explored. An interesting laboratory finding was a high blood uric acid level. In view of this finding, he was seen by consultants to appraise the possibility of gout. He played football this past fall with continued symptoms somewhat alleviated temporarily by frequent injections of procaine hydrochloride. After the operation the patient was seen in December, 1957, and January, 1958, and in the evaluation by the arthritis unit of the University of Michigan no specific diagnosis of arthritis could be proved. Laboratory tests failed to reveal any elevation in the blood uric acid level. Diagnosis was tendinitis of the right posterior tibial tendon.

Summary

With the great increase in sports participation in schools and colleges, it behooves those interested in reducing the incidence of injury in sports to organize sufficiently accurate reports of types of injuries and the disability period of each. To determine the true incidence of injury in sports on a national or regional basis, we must record and report. Each sports participant should be conscious of his "bill of rights."

Coaches of high school and college teams should be relieved of responsibility for all athletic injury, and a team physician should be present at all contact sports sessions, whether practice or game. He, and he alone, must assume all medical prerogatives.

PROTECTING THE BOXER

Ira A. McCown, M.D., New York

Boxing is truly an international sport whose members represent many creeds, races, religions, and nationalities. Its popularity and wide appeal in this country have made it the great American pastime of contemporary sports. It is classified as one of the so-called body-contact sports, along with baseball, football, basketball, hockey, and other similar games, during the performance of which actual body-contact occurs. In boxing, this contact is not only more frequent but often more severe and, on occasion, serious injuries or, rarely, a fatality may result. Thus, boxing has often been considered the most dangerous of all the competitive sports.

Until recently, little thought or concern was given to the safety and welfare of the boxer, in or out of the ring. Many factors contributed to this apathy and apparent negligence, the most important of which was that the very nature and concept of the sport were such that any added measures, other

It is possible to prevent death and severe disability in boxers by enforcing certain medical standards and requirements. These include an adequate medical department, basic medical examination of boxers, adequate supervision and equipment at the ringside, periodic examination and retirement of boxers handicapped by previous injuries, semiannual physical examination of referees, and annual examination of judges. Boxers in New York state must be licensed on the basis of rigid annual examinations, and two physicians are required to be at the ringside for all bouts in that state. Systematic research into types and causes of injury, especially to the brain, the kidneys, and the skin, has led to substantial gains in safety. These gains are manifest not only in recent statistics for injuries and mortality but also in the liberalization of policies granted to boxers by insurance companies.

Medical Director, New York State Athletic Commission; Visiting Surgeon, Mt. Morris Park Hospital; and Associate Visiting Surgeon, Harlem and Sydenham Hospitals.

Read in the Symposium on Sports and Sport Injuries in the Session on Sports before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

than the boxers' physical endurance and ability, were not only unnecessary but harmful to the best interests of boxing. The serious injuries incurred in boxing have too often been accepted and explained as unfortunate but unavoidable accidents, inherent in the sport.

The time-honored skills in which the art of self-defense and offense are basic remain the most reliable weapons in the protection of the boxer in the ring. There is no genuine substitute for these defensive skills and offensive tactics, and they can be attained only by a carefully planned and supervised boxing program. Relatively few boxers, endowed with natural ability and athletic talent supported by adequate training and experience, have been so fortunate as to escape serious injury during their ring careers without the aid of additional safety precautions and medical supervision.

The amateur is generally more closely supervised and carefully protected than the professional boxer. The protection which is so necessary to the amateur boxer in this developmental stage of his ring career is in direct proportion to the intimate relationship with and the personal interest given him by his local club or the social or religious organization through which he is sponsored.

The professional boxer is not so fortunate, and for years professional boxing has universally been considered the most dangerous and risky of all the competitive sports. There will always remain a small but persistent minority who sincerely believe that the dangers and disadvantages inherent in boxing far outweigh any positive values claimed for the sport and that it should be abolished. Many sports authorities and physicians mistakenly believe that the incidence of fatalities and serious injuries is greater in boxing than in any of the other body-contact sports.

Gonzales,[1] in a report of fatalities in competitive sports based on a study over a 32-year period from 1918 to 1950, found that there were more deaths in both baseball and football than in boxing during that period: 43 in baseball, 22 in football, and 21 in boxing. His conclusions based on that study were that "32 years of boxing competitions have produced fewer deaths than occur in baseball or football, in proportion to the number of participants, and far fewer deaths than result from daily accidents. It seems that the moral and physical benefits derived from boxing far outweigh the dangers inherent in it or any of the other competitive sports."

The nature, methods, and objectives that have traditionally been identified with professional boxing have been considered so absolute and all-important that any medical supervision or measures for the protection of the boxer have often been reluctantly accepted by him or rejected by those promoters in charge of boxing. The old concept of winning at any price or "going down like a champ" has all too frequently exposed the boxer to unnecessary risks and serious injuries. An equally untenable and inhuman practice of permitting the fight to continue just for the sake of pleasing a few irate and frenzied fans at ringside, even though it is apparent to any impartial observer that a catastrophe is imminent, has produced mounting criticism and disfavor of the sport.

From 1946 to 1951, seven deaths occurred among professional boxers in New York state. This was a marked increase over former years and it clearly revealed the need for better medical supervision and more adequate safety precautions in professional boxing. Unfortunately, there has been little interest shown by physicians and sports officials, or by the medical profession generally, in the medical aspects of professional sports.[2] This applies particularly to boxing, in which there are no available statistics or data sufficiently accurate or informative enough to be of value in determining the medical status of boxing, past or present. Furthermore, there are factors inherent in boxing which have made it difficult to plan or establish any long-range or satisfactory medical program for this sport. Unlike baseball, football, and basketball, which are seasonal team sports, boxing is an individual, year-round sport and the average boxer is a globe trotter and does not confine his ring activities to any one state or locality.

New York State Athletic Commission

In New York state, professional boxing, since 1920, has been under the supervision and control of the State Athletic Commission, appointed by the governor. The chairmen and other members have consistently been men of outstanding ability and accomplishments in government, business, law, and sports. Their contributions to boxing have been many and varied, and the great strides and advancements which have been made in this sport over the past 35 years have been made possible largely because of the commission's humane interest in and deep concern for the personal safety and welfare of the boxer.

Up until 1948, the local clubs and the boxers' managers assumed the financial responsibility for the medical welfare of their boxers. The commission approved physicians who examined the boxers and acted as ringside doctors and were experienced and capable men, many of whom have spent most of their professional careers in boxing. Dr. Vincent Nardiello was the dean of boxing and ringside physicians until his voluntary retirement in 1957. He has unquestionably examined more boxers and served as ringside physician at more bouts than any doctor in ring history, and he has properly become the family doctor and medical adviser to a number of boxers and sports officials identified with boxing. It is largely due to the untiring efforts and services rendered by such dedicated physicians that many boxers have been spared from serious injury and disability during their ring careers. Moreover, their contributions to the medical phase of boxing has made possible much of the progress which has been made in professional boxing today.

As in other sports and occupations, the performance of which may be hazardous and dangerous at times, a decision had to be made concerning the future of boxing in New York state. Skepticism and doubts by many sports-minded individuals and groups and ardent boxing fans were expressed. Further opposition by those who have traditionally opposed boxing in any form, insisting that it could never be made a safe and humane sport, served only to confuse and prejudice the thinking of fair-minded and impartial officials. Against this confusing background was the usual problem of the cost and financial responsibility of any worthwhile medical program for boxers. The boxer could not afford to and the clubs and promoters could not be depended upon to finance and maintain such a program.

Fortunately for boxing, the state expressed its complete confidence in the sport and faith in the boxer, as it had on previous occasions when the future was threatened. It accepted its responsibility for and discharged its obligations to the boxer by the appropriation of the necessary funds for the establishment and maintenance of the first comprehensive long-range program for boxing. A brief outline and discussion of the organization and functions of the medical department and its accomplishments over the past six years, during which time most of its measures and recommendations were in operation, form the basis of this report. Included is a statistical study of the medical results achieved in boxing during this six-year period, from 1952 to 1957.

The first medical advisory board for boxing was formed in New York when Governor Dewey appointed this body in 1948. It consisted of nine members, including a chairman all of whom are outstanding specialists from medical schools and leading hospitals in the state. These authorities in sports medicine included a neurologist, psychiatrist, orthopedist, ophthalmologist, internist, physician in industrial medicine, surgeon, and dentist. While, theoretically, this board was primarily created to serve in an advisory capacity, the athletic commission wisely recognized and respected the scientific and medical achievements of this board to the extent that it was given the responsibility and authority in establishing and maintaining a comprehensive medical program for boxing.

Under the leadership of the present chairman, Dr. Marvin A. Stevens, an orthopedic surgeon who for years was a prominent football coach and is a recognized authority in sports medicine, nearly all of the many medical recommendations and safety measures sponsored by the medical advisory board have been approved and adopted by the commission. Most of this program has previously been reported in outline form.[3] Hence, only those measures which have been either omitted or only briefly mentioned and have real merit will be stressed.

Medical Standards for Boxing

Medical standards and requirements for boxing are (1) a modern, adequately staffed and equipped medical department, (2) basic standards and requirements for the medical examination of boxers, (3) adequate medical supervision and equipment for the boxer at ringside, (4) periodic examination and evaluation of poor medical and boxing risks, and, (5) semiannual physical examination of referees and annual examination of judges. There are now 36 commission-approved physicians for the examination of boxers in New York state. There are two full-time, trained technicians who take x-rays, electrocardiograms, and electroencephalograms and do the routine laboratory work required on boxers and officials. The medical department is completely equipped with all the facilities and instruments necessary for the physical examination of the boxer.

Each boxer before being licensed to box in New York state must receive and pass a rigid annual physical examination, including routine x-ray of heart and lungs, electroencephalogram, blood and urine examination, and other special examinations as indicated. Special attention is given to examination of the eyes, and there is a minimum requirement of 20/100 vision in either eye (which can be corrected to normal with glasses) with no demonstrable pathology in either eye. Additional routine examinations include the five-day prebout physical, noon-day weigh-in, and immediate prebout and postbout examinations. These findings are recorded on appropriate record and injury report forms. Special attention is given those boxers who sustain a knockout and they are required to have a neurological examination and an electroencephalogram before reinstatement.

Since 1952, two physicians are required to be at ringside for all bouts in New York state. They are supplied with a well-equipped medical kit containing first-aid dressings, suture materials, antiseptics, and appropriate drugs for the resuscitation and emergency treatment of the injured boxer.

All boxers who are susceptible to recurrent injuries or who sustain six or more consecutive losses are carefully evaluated by the commission and reexamined by the medical department. Such individuals are considered candidates for serious injury, and accordingly most of them have been medically disapproved by the board and retired by the commission. It is felt that this precautionary measure has saved many boxers from serious injury or possibly a fatality in the ring. Another valuable safety measure to spare the boxer further and possibly more serious injury is the timely intervention by the referee in stopping the fight on either his decision or that of the ringside physician. Even today far too many fights are allowed to continue when the boxer is helpless, with his arms dangling at his side and taking an unmerciful beating by his opponent. Such an uneven and one-sided contest should be halted minutes earlier rather than seconds later.

Safety measures and equipment required at ringside include (1) a new type ring padding replacing the old felt pad, (2) substitution of 8-oz. for 6-oz. gloves for all except championship bouts, (3) properly fitted mouthpieces to be worn by the boxer during the fight, (4) a portable resuscitator with oxygen equipment, available at all rings, and (5) 30-day automatic minimum suspension for any boxer who sustains a knockout, technical knockout, or other injuries of sufficient severity.

The replacement of the old felt padding by the new plastic ensolite fiber board pad (the result of over two years of exhaustive research), under the ring canvas, has largely eliminated the fatalities from serious head injuries, which were so prevalent when the old felt pad was in use. There is no longer in evidence the back and forth rocking of the head on impact of the occiput against the ring canvas which was commonly observed before this new type of pad was introduced. It is generally believed that this so-called acceleration-deceleration phenomenon which resulted from a knockout, as previously described, was the cause of those direct and contrecoup injuries and serious hemorrhages in the brains of boxers. Certainly, the incidence and severity of head injuries in boxers have been significantly fewer since this safety device was introduced.

The automatic 30-day minimum rest period, which is also honored by all states and municipalities who have a reciprocal working agreement with the New York Athletic Commission, prevents the injured boxer from getting back into the ring before he has been pronounced physically fit for fighting. The various commissions are simultaneously notified by bulletin when the boxer has been medically approved to resume fighting.

Clinical Investigation of Trauma

Clinical investigation and studies of various types of trauma associated with boxing include (1) ringside study of knockouts and frequency of head blows correlated with neurological examination and electroencephalographic patterns, (2) examinations before and after bouts to determine urologic trauma, and (3) comparison of the abrasive and irritant effects of rosin versus calcium carbonate.

The study of "Observations on the Clinical and Brain Wave Patterns of Professional Boxers," by Kaplan and Browder,[4] was reported in 1954 before the section on nervous and mental diseases of the American Medical Association. This marked the first attempt of any experienced neurologist to observe and study at first hand during the progress of a fight, and immediately thereafter, the average number of blows to the chin and head of boxers in the course of a fight and the pathophysiological changes which contribute to and result from a knockout. Kaplan served in the capacity of ringside physician while conducting these investigations, and in addition to his detailed observations made movies including slow-motion pictures of many encounters, with special emphasis on head blows, in particular those producing knockouts. He noted that most of the blows aimed at the chin or head were either blocked or fell far short of their mark.

His observations and deductions concerning the most probable causes of a knockout and unconsciousness from a blow to the chin or head are as follows: "A blow from a human being with a padded gloved fist probably is not forceful enough to produce any direct damage to the brain. Most dazed and unconscious states are due to an excessive inflow of stimuli from many sources. I actually believe that boxers become unconscious from a head blow because of the very rapid turning of the head when it is struck, thereby activating the vestibular mechanism to excess. Similarly, a blow to the abdomen may produce stimuli to the nerves in that area and cause an excessive inflow of impulses to the reticular area of the brain stem. When the cells in the reticular mechanism receive this tremendous bombardment of incoming nerve impulses, they may block off for a period of time. Any severe pain can cause a person to become unconscious in a similar manner. This may be a protective mechanism on the part of the body. I realize that this is highly theoretical, but it is certainly as good as any of the present day theories."[5] Certainly, Kaplan's observations and deductions are based on an abundance of clinical and laboratory data, as there are now available over 3,000 serial electroencephalograms in boxers. He has challenged the so-called punch drunk syndrome, originally described by Martland[6] in professional boxers, and more recently revived and emphasized by Jokl.[7] Kaplan believes that the clinical picture and pathological findings associated with this syndrome are not peculiar to boxers but have been found in the average populace as frequently as in professional boxers.

There have been two excellent studies of urologic trauma in boxers; one is a report on acute renal trauma in boxers by Amelar and Solomon.[8] They reported on the prebout and postbout urine examinations in 103 professional boxers: albumin appeared in 68%; red blood cells in 73%; and granular or hyaline casts in 26%. They concluded that the effects of acute renal trauma sustained during a fight can be determined in part by an appropriate urinalysis and that further investigations were indicated on a broader basis to determine the true incidence, severity, and effects of urologic trauma in boxers.

The other and more complete investigation of urologic trauma in boxers was conducted by Kleiman,[9] a urologist. He analyzed the results of his studies of 764 boxers over a three-year period and stated that there should be a thorough clinical and laboratory investigation of any candidate for boxing who has a history of any genitourinary disorder or renal pathology. Excretory urography should be included, when indicated. Kleiman conclusively demonstrated that trauma to the kidney by boxing, when superimposed upon preexisting pathology or anomaly, may justify the retirement of the boxer because of the likelihood of serious renal damage. In contrast, in a study of 20 retired boxers, a complete urologic survey did not reveal any pathology that would not ordinarily have been present in any similar group of nonboxers.

Dr. Max Moses[10] performed experiments in determining the relative superiority of calcium carbonate (talc) versus rosin as antislip agent and as to their respective irritating properties in the eye and on open wounds. Adult albino rabbits were used. His conclusions were that while calcium carbonate was slightly less irritating to the eye and in wounds, it produced a foreign body reaction and was more difficult to remove. Rosin was far superior as an antislip agent, and over-all rosin is superior to calcium carbonate and should not be replaced by it on the ring canvas.

Medical evaluation and statistical report of a six-year study, 1952-1957, of professional boxing in New York state revealed that of 9,871 participating boxers there were 259 knockouts, 718 technical knockouts (502 as a result of injury and 216 from inability to defend self), 9 serious head injuries requiring hospitalization, 16 eye injuries (11 corneal injuries and 5 detached retina), 29 fractures (12 metacarpal, 11 nasal, 3 of the jaw [mandible], and 3 of the phalanges), and 4 dislocations of the shoulder; 138 boxers retired or were denied license, and there were no deaths.

The absence of mortality or serious injuries in boxers during this period (there were seven deaths in the six-year period just preceding this study) is gratifying and indicates that these favorable results justify the belief and confidence in a medical program as outlined which has proved adequate for the maximum safety and welfare of the boxer. This confidence has been further demonstrated by the sizable increase of medical benefits from $500 to $750 and death benefits from $3,500 to $7,000, and these were effected without any increase of premium rates to the boxer.

Summary

The New York State Athletic Commission and its medical advisors have advocated and adopted medical measures and recommendations for the safety and welfare of the boxer. These many and varied medical measures, safety precautions, standards, and requirements, including clinical studies and research, can make boxing safer. The absence of mortality and the relatively few serious injuries in this group (less than that observed in other body-contact sports), as revealed by the medical statistics involving 9,871 boxers who actively participated in boxing during the six-year period, 1952 to 1957, when this program was enforced, strengthens confidence in the efficacy of this program in the protection of the boxer. Professional boxing can survive and prosper under such a program.

2225 Fifth Ave. (37).

The Cornell Aeronautical Laboratories of Buffalo, N. Y., produced the plastic ensolite fiber board pad. The Lederle Laboratories, Division of American Cyanamid Co. of Pearl River, N. Y., made the experiments on rosin versus calcium carbonate for the ring canvas.

Miss Alice Oliveri and Miss Kathy Holadak performed the laboratory and technical work for this study.

PENETRATING RADIATION FOR CANCER.—Since there has been no significant increase in cancer cure rates in recent years that can be attributed to the treatment method alone, new and more radical procedures have been introduced in an effort to improve the results. In radiation therapy this has taken the form of supervoltage generators and the use of high energy sources of radiation such as Cobalt 60 and Cesium 137. As this trend gains momentum, the place and future of orthovoltage therapeutic radiation (250 to 400 kilovolts) must be considered. General agreement is that supervoltage radiation offers an increase in depth dose and fewer local and systemic reactions, but it is too early to assess any change in cure rate. Measured against this is the danger of deep tissue damage, less relative biological efficiency and increased costs. In view of our ignorance regarding cancer, abandoning proved procedures prematurely is unjustified. The most promising trend lies in improved training and in the skillful use of what we have.—S. R. Baker, M.D., Orthovoltage Therapy, *California Medicine,* December, 1958.

PREVENTION AND TREATMENT OF SKI INJURIES

Hans Kraus, M.D., New York

Injuries are less frequent in skiers who are in good physical condition, are skilled, and have good equipment. The treatment of most injuries in skiing mishaps is based on general orthopedic principles, but the idea of immediate mobilization needs to be emphasized. If pain and muscle spasm make mobilization difficult, the necessary exercise can generally be given after use of an ethyl chloride spray on the painful area, provided major ligament tears are excluded. There is no adequate explanation for the deep effect of the surface anesthesia, but the pain-free interval can be used to restore the muscle to normal function. Four case histories illustrate the complete rehabilitation of patients with fractures of the humerus, pelvis, and ankle and partial tear of the medial collateral ligament of the knee.

Skiing is here to stay. Its ever-increasing popularity can be witnessed by the number of ski resorts and lodges that have sprung up in all parts of the United States, by the special trains and other transportation facilities provided when "conditions" are right, by the publications devoted to this subject, by the endless conversations of the ski enthusiasts, and by the fact that, even if Nature doesn't provide snow on the slopes, man will make it!

Yes, skiing is here to stay—but with it comes the problem which is the subject of this paper, namely, the "ski injury." There are two main causes of injury: lack of skill and lack of proper physical condition. The prevention and the treatment of ski injuries create a definite and interesting problem to any physician in the United States today.

The value of the lessons learned in the treatment of ski injuries exceeds the particular application. It can be used to great advantage in the management of other athletic injuries, as well as occupational injuries.

In an effort to supplement available literature and our own experience, questionnaires were sent out to a number of physicians in skiing resorts, to ski patrol men, to ski schools, and to prominent skiers. The answers received [1] added substantially to our information on the cause and prevention of ski injuries.

Athletic injuries are those produced by circumstances inherent in respective athletic performances. They are, therefore, characterized by exposure to recurrent identical trauma and strain, making reinjury likely. Treatment includes managing the injury itself, avoiding recurrence, and permitting return to the activity as soon as possible.

Ski injuries in particular show very typical recurring hazards, which can be dealt with and which can be minimized. Since skiers usually insist on returning to their sport as quickly as possible and since this invariably offers an opportunity for identical trauma, an interesting treatment problem is presented, primarily in the phase of rehabilitation; that is, restoration of function to the greatest possible degree in the shortest possible time.

Just as rehabilitation of the ski injury deals primarily with restoration of muscle function (i. e., normal strength and flexibility in injured part), prevention of ski injury deals with assuring the skier of minimum physical requirements for safe conduct of the sport.

It is difficult to prove to what degree the physical condition of a skier is responsible for accidents. Figures available have to be evaluated with care. However, some definite information points to the fact that good physical condition is extremely important. Two instances may serve as illustrations: 1. A Westchester, N. Y., ski club averaged 5,000 skiing days during 11 years. During this time pre-ski conditioning was practiced. No fractures, and only two mild sprains, occurred. When the pre-ski conditioning was given up, three fractures occurred during the first year. 2. At the North Country School, Lake Placid, N. Y., similar facts are shown. An enrollment of 50 children, aged 8 to 14 years, accumulated a total of 5,000 skiing hours. Seven fractures and five sprains occurred. When a pre-ski conditioning program was adopted, none of the children participating in the program suffered accidents in the first year (5,000 skiing hours); two boys who did not do conditioning work suffered fractures of the leg.

The fact that ski injuries occur rarely in ski schools is well established. At the Mt. Mansfield Ski School only one fracture occurred in 7,310 hours of instruction, and in Switzerland there was only one "accident" in 3,498 hours of instruction.

Associate Professor of Physical Medicine and Rehabilitation, New York University.

Read in the Symposium on Sports and Sports Injuries in the Session on Injury in Sports before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

Prevention

The most important factor in preventing ski injuries is the skier himself. Most ski injuries are due to insufficient know-how or to poor physical condition of the skier. Speed, snow conditions, visibility, and trail conditions are hazards only when they are not properly recognized and managed.

The statistical evaluation of ski injuries is more difficult to ascertain than that of any other athletic injury. In order to compare figures accurately, they would have to be computed in terms of downhill feet, and though this has been done in some instances even this computation compares unequals; 1,000 ft. of downhill run by an expert cannot be compared to the amount of skiing done by a beginner or a racer.

It is obvious, even to the uninitiated, that equipment plays an important role in the prevention of ski injuries. A survey, supported by most personal opinions, reveals that, while release bindings are by no means safety bindings, they do offer a worthwhile improvement on the chance of avoiding injury. At Garmisch-Partenkirchen, Germany, of 17,500 persons who rented nonrelease bindings, 74 sustained fractures; of 45,043 who rented release bindings, 11 sustained fractures. At Stowe, Vt., nonrelease bindings were used by 48% of skiers, in which group 66% of accidents occurred.[2] Also, the use of less pointed poles would decrease some of the stab injuries. Sharp edges have increased the incidence of cuts, but it is unlikely that this, even if generally known, would persuade any skier to make a change.[1c] Clothing and boots have now been generally developed to the point where most skiers are properly protected. And, since skiing areas are usually close enough to warming facilities, frostbite is not a serious hazard.

As mentioned, strength and flexibility of the skier play the largest part in avoiding injuries by making fatigue less likely and by improving the ability of the skier to meet inevitable spills.[1] A physically adequate skier will know when he is warmed up and will consciously try for warm-up by some uphill walking and cross-country running, and this same skier will realize when he is tired and will avoid that famous last run.

Treatment

Formerly the injured skier came in with the question, "Can I ski again?" Now, even the more severely injured come in with the question, "When can I ski again?"

The management of ski injuries, which, of course, basically rests on generally accepted orthopedic principles, is thereby given an added problem, namely, how to restore full function in the shortest possible time. Attempts to answer this demand have resulted in experience valuable in the treatment of other athletic injuries as well as occupational injuries. The special problem of ski injuries is one of rehabilitation and, more specifically, one of restoration of muscle strength and flexibility.

Clay Ray Murray and William Darrach used to say that the ideal treatment of fractures would be to "wish the bone back in place, to keep them there by a wish, and to start active motion of the injured parts at once." It is this principle that made them advocate open reduction and internal fixation wherever possible. The best treatment is immediate mobilization, not only where internal or external fixation have been necessary but also where immobilization can be eliminated by immediate active measures.

A contraindication to immediate movement is pain and subsequent muscle spasm. Use of local measures in treating the pain and spasm make it feasible to immediately mobilize not only sprains and strains but fractures as well if the position is acceptable and displacement does not have to be feared.

Fractures treated by immediate mobilization include fractures of the pelvis (os pubis), fractures without displacement of the short bones of the foot (intraboot injury),[1a] fractures of the head of the humerus, fractures of the metacarpals, fractures of vertebrae, if uncomplicated and if no pedicles are involved,[3] fracture of transverse processes of vertebrae, and fractures of the ankle without displacement of the lateral malleolus, if not combined with ligament tear. We prefer immediate mobilization for reduced dislocations of the shoulder and elbow, and for fractures of the tuberosity of the humerus. At New York University–Bellevue Medical Center fractures treated over a period of about two years included impacted humerus (87), pelvis (62), vertebrae (47), metatarsal (63), calcaneus (43), and tibial plateau (38).

Immediate mobilization of sprains of the ankle and knee and strains of the lower part of the back, of the calf, or of the hamstring tendons restores function[4] in a shorter period of time, and if followed by adequate therapeutic exercises produces better long-range results. Of 126 persons with injury of the medial collateral ligament of the knee, 51 (40%) had had previous injury. Of 70 who were followed for from 2 to 15 years, none had reinjuries, 62 had skied again, with no complaint, 5 had not skied again, and 3 had skied again, with reactions of pain and swelling.

Before deciding on immediate mobilization, however, it is important to exclude major ligament tears, especially in ankle injuries (fig. 1). Tears in the collateral ligament or intraosseal ligament as well as tears of the medial collateral ligament or cruciate ligament of the knee are not to be classified as sprains. They frequently need surgical repair, sometimes immobilization in plaster casts. The following case histories may serve as illustrations.

Report of Cases

Case 1.—The patient fell while skiing on March 3, 1956. X-rays showed comminuted fracture of the anatomical and surgical neck and greater tuberosity of the right humerus. He was seen in consultation by Dr. Frank Stinchfield. At his suggestion immediate mobilization was started. The patient came to see me on March 9 for the first treatment, which consisted of surface anesthesia and exercises. On March 23 there was no pain and abduction was possible to 90 degrees and scapula-humerus abduction to 80 degrees. There was steady improvement. On May 18, 1956, there was some limitation of inward rotation but otherwise full range with slight residual weakness. The patient had been skiing since three weeks after the accident without discomfort. On reexamination Nov. 30, 1956, he had full range and power, with no complaints. At follow-up examination there were no complaints (fig. 2).

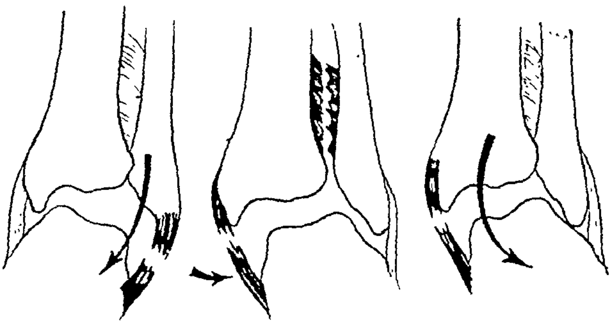

Fig. 1.—Serious injuries, drawn from x-ray negative. *Left,* lateral collateral ligament; *middle,* inferior tibiofibular ligament; *right,* medial collateral ligament. (Supplied by Charles Neer.)

Case 2.—The patient fell while skiing on Dec. 29, 1948. This patient was placed in a hammock at a local hospital. X-rays showed evidence of fracture of the pelvis with fracture site located in the inferior ramus of the pubis and at the junction of the superior ramus of the pubis with the ischium, both on the left side. Traction was suggested. The patient could not void and was extremely uncomfortable. I saw the patient on Dec. 30, 1948. Therapy was started immediately with ethyl chloride spray and exercises. Immediately after removal from the hammock and start of active motion exercises and ethyl chloride spray, the patient improved and voided spontaneously. On Jan. 3, 1949, partial weight-bearing was permitted and gradually increased. Two weeks after the accident the patient returned to college. On reexamination Jan. 31, 1949, there was no atrophy and the patient had no complaints. At follow-up examination there were no complaints. The patient is able to ski.

Case 3.—The patient fell while skiing on Feb. 26, 1953, and suffered a fractured ankle. Stress pictures showed some medial displacement. The patient was a ski instructor, therefore surgery was recommended (Dr. Frank Stinchfield). There was a complete tear of the deltoid ligament which was repaired, and a Rush nail was inserted to the lateral malleolus. The patient's ankle was in a plaster cast until March 10th, then was placed in half-shell cast. The exercise regimen was supported by electrotherapy. On March 31, 1953, the patient had full range of motion with exception of some limitation of *Vorlage* and inversion. Treatment was continued until April 1st when the patient left New York with his leg in a short leg brace. There was almost full range of motion in the ankle joint and good strength. At follow-up examin in February, 1958, the patient stated he had been skiing e since with no difficulties (fig. 3).

Case 4.—The patient was first seen on Jan. 25, 1939. He had fallen while skiing and twisted his right knee eight d prior to visit. The history revealed a football injury 10 ye previously with repeated episodes of knee injury with swelling. The present diagnosis was partial tear of medial collater ligament, considerable effusion, and marked vastus atroph. The patient came in daily for ethyl chloride spray and exercises and was free of pain by Feb. 2, 1939. He skied again, against advice, on March 2nd and returned from skiing with some pain and swelling. Treatment was resumed. Operati was considered but the patient wished to continue on conservative regimen. He improved on therapy with exercis and ethyl chloride spray and was almost fully rehabilitated by May 27th. This patient has been followed closely, as h has returned with various other ski injuries. However, he ha had no further difficulty with the treated knee.

Comment.—This patient had had a number of injuries t the knee joint. These episodes ceased entirely after rehabili tation to complete strength.

Technique of Immediate Mobilization

The technique of immediate mobilization in cludes local relief of pain and therapeutic exercise as the most important factor in the treatment o athletic injuries.[5] A brief description of the tech nique follows.

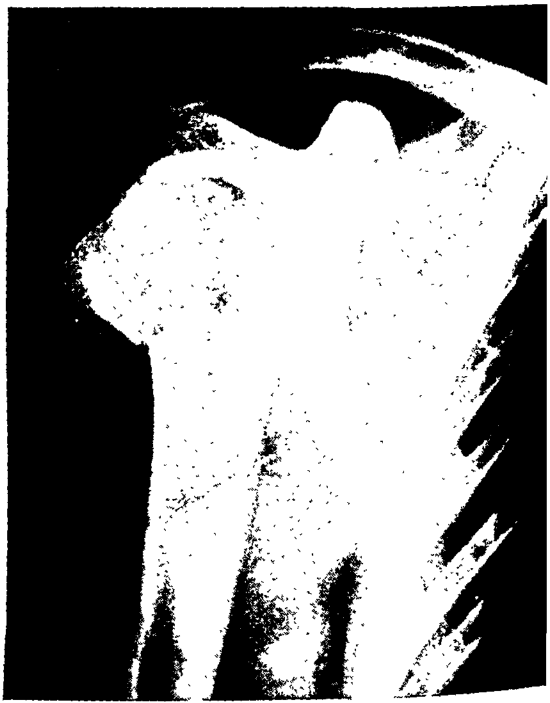

Fig. 2 (case 1).—Comminuted fracture of anatomi and surgical neck and greater tuberosity of right humer

The pain is located by active motion. Eth chloride is then sprayed on this area. The patie then starts active movement of the part involve in the direction in which motion has been painf and limited. As the patient increases his range, ne painful areas will develop. These areas must aga be sprayed, and active motion continued. Treatments last from 10 to 30 minutes, and should be carried out within limits of pain.

Immediate use of the affected part may be allowed in patients able to perform normal movement, but excessive strain and sudden movement should be prohibited. Patients with more severe disabilities should be advised to rest, but all patients should be urged to continue the active movements that they have been taught. The exercises should be performed from a minimum of twice a day to as often as once every hour, for approximately five minutes. While a single treatment will suffice in cases of minor involvement, patients with more serious difficulty require frequent treatment: daily during the first week and later every other day (fig. 4).

An effective treatment should not require the application of anesthetic after the second week. Therapeutic exercises must continue, and increase in scope, until normal muscle power is restored. Once motion is instituted, immobilization should not be used, as it is contrary to the basic principle. It should be stressed that active motion, though unquestionably necessary, should never be brusque or abrupt so that painful spasm in muscles will not be further aggravated.

Compared with injection of procaine hydrochloride into the muscles and ligaments, the use of ethyl chloride has certain definite advantages: 1. The application is simple. 2. Repeated application is possible with minimum difficulty and risk. 3. Large areas can be controlled that would otherwise require quantities of procaine hydrochloride. 4. Ethyl chloride does not mask bone or ligament injury. 5. It is better as a diagnostic means, since it is more selective. 6. There is less risk of a local after-effect and there is no general after-effect, such as occasionally occurs after the administration of procaine hydrochloride. 7. There is no danger of infection.

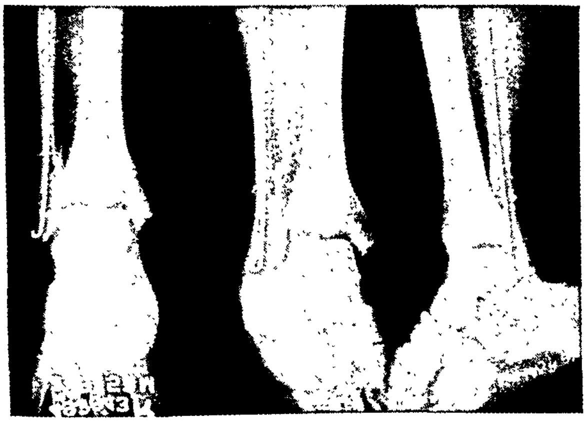

Fig. 3 (case 3).—Fracture of distal end of fibula, with fixation.

The administration of surface anesthesia is only the first step in the treatment of painful muscle spasm. Exercise is the necessary second step. Without it, the use of surface anesthesia would accomplish little more than the use of gas or ether in surgery without operation.

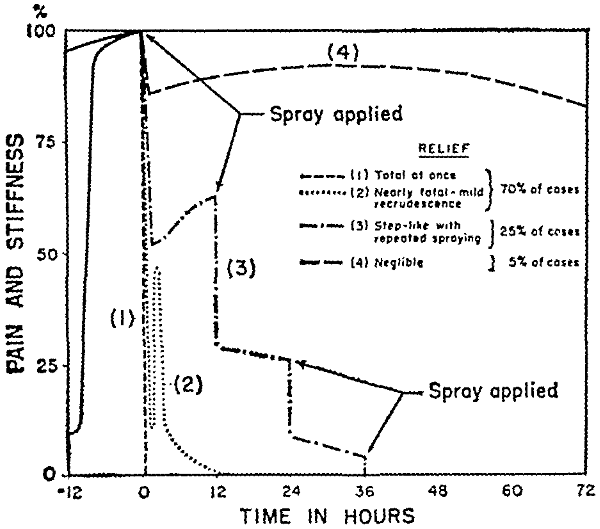

Fig. 4.—Response of acute "stiff neck" to ethyl chloride spray. (Reproduced from Travell,[4d] with permission of *Archives of Physical Medicine and Rehabilitation.*)

Exercises must be performed immediately after application of the anesthesia. These should be exercises to restore elasticity and increase relaxation and length of muscle and should always be performed below pain and fatigue limits. Scattered dosage from two to five minutes, and exercises every one-half to one hour should follow. The supporting prescription may call for particular or complete rest between exercises.

The most common mistakes made in treatment with surface anesthetics and exercises are (*a*) failure to cover the full painful area with anesthetic, (*b*) overdosage of violent exercise, (*c*) neglect of pain limit, (*d*) neglect of home exercises, (*e*) neglect of supportive prescriptions, (*f*) neglect of follow-up treatments, (*g*) failure to explain properly to the patient and to arouse the necessary cooperation, and (*h*) faulty indication.

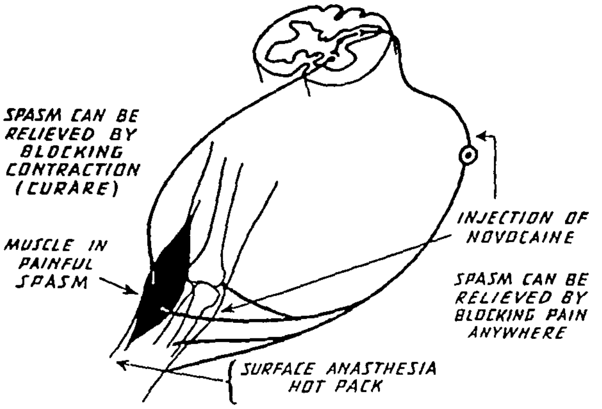
As to the theory involved: Pain originating in one portion of the sensory motor chain leads to reflex muscular spasm and locking of joints (fig. 5). This sensory motor chain consists of the following elements: Sensory nerve, nerve center, motor nerve, muscle and sensory nerve. Pain originating in the course of this chain leads to muscular spasm. Elimination of pain at any point in the chain results in the breaking of the chain, and, therefore, in relaxation of the muscular spasm. This may be achieved directly by the injection of an anesthetic into the muscle, joint ligament, sensory nerve, or spinal cord.

If the pain-free interval is used to restore the muscle to normal function, spasm does not recur, or it recurs with much less intensity. It has been our experience that, on the basis of this chain, cutaneous anesthesia similarly relieves deep-seated pain in muscular spasm.

There is no adequate scientific explanation for the deep effect of surface anesthesia. However, the underlying physiological reason presents an interesting field for exploration. And, it should again be emphasized that surface anesthesia alone, without active motion, will not achieve good results.

When the acute phase has subsided, strengthening exercises to weak muscles, as well as limbering and stretching exercises to tight muscles, must gradually be increased. To be of value these exercises must exceed easy performance and at the same time should cease before the point of fatigue so as to avoid setbacks.[4a]

As soon as the joint can be moved through full range, weight lifting exercises may be added to resistive exercises; but weight exercises are not a substitute for resistive exercises. The weight tolerated through full range is by necessity smaller than the maximum range tolerated in a particular section of the movement.[4a] Active resistance adjusting to these different potentials can, therefore, give a more efficient and complete workout. As long as there is little exercise tolerance, daily sessions are necessary and should be supplemented by frequent periods of movement at home.



SPASM CAN BE RELIEVED BY BLOCKING CONTRACTION (CURARE)
MUSCLE IN PAINFUL SPASM
INJECTION OF NOVOCAINE
SPASM CAN BE RELIEVED BY BLOCKING PAIN ANYWHERE
SURFACE ANASTHESIA HOT PACK

Fig. 5.—Diagram showing sensory motor chain leading to reflex muscle spasm and locking of joints and method for relief.

Once strong workouts are started, three sessions per week are usually all that are necessary but should be supplemented by homework of one or two tolerance sessions each day. Of course, it is true that such extensive rehabilitation programs should be given only where return to the sport is desired, as one must remember that a knee that is perfect for city life may be in great jeopardy when exposed to the hazards of skiing.

Since it is the lower extremity that is most frequently jeopardized in skiing (see table), evaluation of the injury should include comparison of strength with contralateral side (by weight lift or scale test)[4a] (fig. 6). Full range of knee and ankle joint should be restored. The ankle joint should be especially tested on forward bend with the heel on the ground (*Vorlage*). If this movement is limited, it may well be a cause for reinjury. For example, when a skier goes over a bump and tries to bring his weight forward, he will experience a pull on the shortened muscle. This will cause him to unweight his ski, the tip will tend to dive, and the skier will fall with probable injury to the extremity.

*Distribution of Ski Injuries**

Location	%	Type	%
Head	4.3	Shock	1.1
Shoulder	1.9	Stabs	1.3
Arm-hand	2.7	Dislocation	1.5
Back-trunk	0.8	Fracture	31.5
Leg	92.0	Laceration	10.0
Miscellaneous	0.2	Sprain	51.3
		Bumps, etc.	1.9

*Data from the National Ski Patrol System.

The mere passage of time alone does not contribute to full rehabilitation. It can almost categorically be said that daily activities in the city do not prepare the skier for strenuous use of quadriceps and leg muscles nor do they give the required elasticity of the soleus which makes a leg safe for skiing. A study of 500 skiing injuries revealed that 14.2% were reinjuries. Of 126 knee injuries, 40% were reinjuries. A survey of 195 skiers, by the ski patrol at Stowe, Vt., revealed 132 had had no injuries, 41 one injury, 15 two injuries, and 7 more than two injuries.

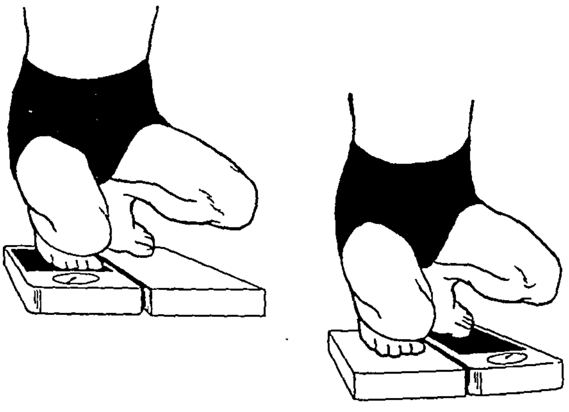


Fig. 6.—Scale test for evaluation of injury by comparison of strength with contralateral side.

Summary

Poor muscular condition is a main cause for ski injury. Physical conditioning before skiing is the best prevention. Weakness and stiffness after injury are among the main causes of reinjury. Therapeutic exercises to restore full function of the injured part are essential to make it possible for the injured skier to return to his sport safely.

The use of ethyl chloride spray and active exercises immediately after sprains, strains, and certain types of fractures has been found most effective in over 25 years of work with that method.

RESPIRATORY PHYSIOLOGY AND SKIN DIVING

Robert W. Keast, M.D., San Francisco

Skin diving with self-contained underwater breathing apparatus (scuba) has hazards that distinguish it both from free diving during short periods of voluntary apnea and from traditional diving with helmet, pump, and connecting tubes. It is also necessary to distinguish between the type of scuba in which the expired carbon dioxide is absorbed chemically, the needed oxygen is added, and the nitrogen is rebreathed from the type in which the expired air is simply discharged into the water as bubbles. Although the latter form is less dangerous, it has its hazards, including air embolism, decompression illness, nitrogen narcosis, oxygen intoxication, rupture of eardrums, and squeeze. Squeeze, the pressing of body tissues into air-filled spaces in the diving costume, is particularly damaging to the eyes. The bulging of the eyes into goggles is hard to avoid, but if a mask is worn instead of goggles the danger can be decreased by discharging air from the nose into the mask whenever pressures increase.

Skin diving as a hobby and as a sport has increased tremendously in the past 10 to 15 years. The introduction of commercially available skin diving equipment has increased the number of divers to almost a million people registered in nearly 400 clubs. Skin diving is not limited to salt water seacoast areas. There are many diving clubs even in such inland spots and inaccessible areas (as far as water goes) as the deserts of Nevada and Arizona.

An increase in accidents and fatalities is the result of the marked increase of the number of people who have taken up skin diving. In California there was approximately one death per month from January, 1953, to April, 1955, besides the many accidents which were not fatal. In skin diving the mortality in any given set of accidents is high—in contrast, for example, to skiing, where morbidity is higher compared to mortality. In order to improve the statistics of injury from skin diving, it is appropriate to describe the injuries and accidents which are associated with it and their prevention and treatment.

Read in the Symposium on Sports and Sports Injuries in the Session on Injury in Sports before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

Free diving is diving after a mild or moderate amount of hyperventilation with a deep breath of air and then coming up when the breath-holding period has passed. There is no external source of compressed air or oxygen in this type of diving. In scuba diving (the letters stand for self-contained underwater breathing apparatus), a demand regulator and source of compressed air or oxygen is used and the individual breathes through a flexible rubber hose. In the case of the "compressed air" type of breathing "lungs," the compressed air is inhaled and the exhaust is released through a one-way valve into the water which bubbles to the surface. In the so-called rebreathers, there is a soda-lime chamber to absorb the carbon dioxide, only oxygen is supplied to the bag, and there is no tell-tale bubble trail on the surface.

Requirements for a safe diver include both physical and psychological components. Skin diving can be exhausting, and it is axiomatic that good physical condition is a prime requirement. Good swimming ability is of paramount importance, and familiarity with water sports in general is of tremendous value. No one with chronic cardiovascular or respiratory type of derangement should indulge in the sport. Obesity is also a detriment. Some patients should be limited to free diving in shallow water. The individual who has chronic ear trouble and who is unable to inflate the middle ear through the eustachian tubes with intranasal pressure will find that he can not dive more than 12 to 15 ft. without pain in his ears and the possibility of rupturing the drum.

There are also psychological requirements for a good or, indeed, even a safe diver. The individual who is very nervous, is easily upset, lacks self-confidence, and might panic at the onset of an emergency should never attempt to dive. The show-off type, the dare-devil who takes chances and loves to show his superiority over others, is a dangerous diver whose diving should be controlled as much as possible.

Man's general problems in skin diving are associated with the fact that he is not designed or equipped to be under water safely. The physical laws of gas behavior all impose limits on his underwater activities. Boyle's law is one of the most important. Briefly stated, Boyle's law says that if the temperature remains constant, the volume of the gas varies inversely with the pressure. The pressure at sea level is 14.7 lb. per square inch (760 mm. Hg). For each 33 ft. a diver goes below the surface, there is an increase of one full atmosphere of pressure. Therefore, at 33 ft. there are 2 atmospheres of pressure absolute; at 66 ft., 3 atmospheres; at 99 ft., 4; and so forth.

In this same context, a given volume of air in the lungs (for instance, 2,000 cc. of air) at sea level before diving will be compressed at 33 ft. below the surface to 1,000 cc. and will be compressed another 33⅓% at 66 ft., then occupying a volume of approximately 667 cc. When ascending, a diver at 33 ft. may inhale a breath of compressed air from a scuba unit, filling the lungs exactly half way, and at the surface the lungs will be completely full and the volume of gas will be twice what it was at 33 ft. Dalton's law states that each gas exerts its own tension in a mixture as though it occupied the space alone, and Henry's law states that gases dissolve according to their partial pressures in a contacting liquid. Thus, in general, the difficulty with man under water lies in the air spaces in his body. The body tissues in general are considered to be incompressible, and, in animal experiments, pressures of over 100 atmospheres have not caused noticeable damage to tissues per se.

Air Embolus

The term "air embolus" has been used to describe the accident which occurs when an individual inhales at increased pressures a full lung of air and then rises rapidly through the water to a much decreased pressure, causing a marked increase in the volume, according to Boyle's law, of the compressed air in his lungs. The lung tissue is fragile and, normally, the increased pressure behind the sternum and against the diaphragm can be felt and will usually be compensated for by a normal exhalation, but a person who is in a hurry to get to the surface is frequently in a state of panic. He may also be under the impression that he does not have enough air. A spastic glottis is the result, and the lung tissue can in a mild case be torn and in a severe case be completely ruptured with the introduction of air emboli into the pulmonary veins returning to the left side of the heart. In one case described in the literature, the air emboli were so universally distributed throughout the body that the cut surfaces of all body organs contained air and were felt to exhibit crepitations.

The signs of air embolus are, essentially, bleeding from the lung, shortness of breath, dyspnea, cyanosis, and collapse. In mild cases treatment consists of placing the patient in the head-down position and supportive therapy for shock. At times recompression to the level at which the patient was before he began to ascend in the water is of benefit. Prophylaxis, of course, in such an accident is much simpler and more effective than is treatment. If all divers understood that there is never a situation in which it would be safe to come up to a shallower depth in the water, after breathing compressed air, without a continuously open glottis and free exchange of air in and out of the lungs, such accidents would be much less common.

An interesting side-light in this particular phenomenon has to do with the individual who has, for some reason, been caught at considerable depth with either a malfunctioning scuba or, more usually, a sadly depleted air supply. If he takes a comfortably deep breath at that stage, takes his scuba mouthpiece out, and then exhales slowly at the greater depths and more and more rapidly as he gets near the surface, he will find that the air in his lungs will be discharged and he will not particularly feel the need of exhaling. This procedure is not essential, necessary, nor indicated in free diving because the diver takes in 1 atmosphere of pressurized air at the surface and dives down to 30 or 40 ft. Then on his way back up the air that was compressed at 40 ft. will expand again but can go no further in expansion than it was at the 1 atmosphere of pressure that he began with at the surface. He took in no compressed air at increased pressure below the surface of the water.

Air embolus can cause death. A diver using a scuba in 20 ft. of fresh water apparently found it suddenly difficult to breathe as the air diminished in his lung. He closed his glottis, kicked for the surface, came up and shouted to the people on shore, but sank again immediately. Postmortem examination disclosed severely shattered lungs. These divers may even die before reaching the surface.

Caisson Disease

Caisson disease (the bends) is caused by increased pressure of nitrogen when one works under pressure. The nitrogen dissolves in the blood stream at a proportion to its partial pressure, according to Henry's law. Then, on decompression from depths, the nitrogen in the tissues and in the blood stream, if not decompressed slowly enough, will cause bubbles which reabsorb slowly and cause what is called "the bends" or "the chokes." Bubbles in the blood stream and tissues cause caisson disease. At 99 ft., at an absolute pressure of 4 atmospheres, nearly 5 cc. of nitrogen is dissolved in 100 cc. of blood; thus, all of the blood of a 155-lb. (70-kg.) man would release 130 cc. of nitrogen and the tissues would release up to 10 times that much. Symptomatology of caisson disease includes pain in over 90% of all cases, associated with the area in which the bubbles are causing difficulty.

The tendons and the cerebral spinal nervous system are two of the most common places that are attacked in caisson disease. The chokes are a manifestation of nitrogen bubble emboli in the pulmonary capillary system with resultant pulmonary edema, usually quite severe. Fat people have more difficulty with caisson disease than do thin people, because of the increased nitrogen solubility in fat as compared to water. The treatment recommended in mild cases is use of recompression to 30 lb. pressure and 100% oxygen at that level for one hour. Then decompression should begin at the rate of 1 lb. of pressure per minute. In severe decompression illnesses, the treatment should be recompression to 75 lb. of pressure, with 50% oxygen, for 15 minutes to two hours, depending on symptoms, and then decompression to 30 lb. of pressure at the rate of 1 lb. per minute and maintenance on pure oxygen for one to two hours. If, however, after 1 hour with pure oxygen at the 30-lb. pressure level, the patient still has symptoms, 30-ft. breathing air is used for 24 hours, then oxygen for 2 hours, followed by 1 lb. per minute decompression rate to normal. Effective treatment in preventing caisson disease is use of a warm compression chamber if no more than three or four minutes have elapsed since the patient left the water and entered the chamber. In one experiment, in 130 dives from 66 to 108 ft. for one-half to two and one-half hours, decompression was begun in an average of six and three-tenths minutes after the divers left the water, and during these dives there were no signs of caisson disease.

For prophylaxis of caisson disease, normal U. S. Navy standard decompression tables are available to the skin diver. Briefly, the depths to which one can dive are estimated from length of time and depth in the water. For example, without any decompression it is generally safe to stay at a depth of 125 ft. for 15 minutes, 75 ft. for 35 minutes, and 30 ft. for any length of time. Time is computed from the moment of leaving the surface until leaving to come up from the greatest depth reached. It is exceptionally difficult to estimate time under water, and only a watch should be considered effective in time measurements. If a diver went 200 ft. down and stayed for 35 minutes, decompression time on coming up would be 22 minutes at 30 ft., 28 minutes at 20 ft., and 46 minutes at 10 ft., with the rise from the bottom at a rate not to exceed 25 ft. per minute, with one minute to come up from the three stops at 30, 20, and 10 ft. This gives 106 minutes of total decompression time from leaving the bottom until reaching the surface. At a depth of 300 ft. for 45 minutes, decompression time would be a total of 5¼ hours at levels from 90 to 10 ft., stopping every 10 ft. One other thing which must be kept in mind in decompression tables is that the effects of any dive which is within 12 hours of the last dive are cumulative, and the diving tables are used by computing the total time of all dives at the last depth. On trips to Catalina, for instance, frequently two or three tanks of air will be used by each diver and caisson disease is likely in a depth of usually 75 to 150 ft. because of the failure of the divers to add their diving times together.

Other Risks of Skin Diving

Nitrogen Narcosis.—The syndrome called nitrogen narcosis or "raptures of the deep" is also a result of pressure of the inhaled air. Below a level of 100 to 160 or 170 ft., depending on the individual, there is a gradually increasing feeling of exhilaration and euphoria, similar to an acute alcoholic bout and described as a feeling of wanting to remove the mouthpiece of the scuba unit and hand it to a passing fish because it is not needed. Fatal errors in judgment may occur as a result of this narcosis. There have been frequent deaths, due partly to this syndrome, of persons who have tried to break the underwater, deep-diving scuba records. The record at present is in the vicinity of 375 or 380 ft. The treatment for this syndrome is immediate return to shallower depths where symptoms immediately disappear. Prophylaxis is to stay out of the lower depths unless essential. Use of up to 90 or 95% helium with oxygen, used only at the lower depths, will relieve a marked share of the symptoms of nitrogen narcosis.

Oxygen Poisoning.—Oxygen poisoning is the name applied to a syndrome which is the result of breathing oxygen at markedly increased pressures. The depth reached before this syndrome begins varies in different persons, but generally the limit of oxygen for any length of time is considered to be about 30 ft. Some have gone down 40 or 45 ft. for one-half hour without difficulty, but the more exercise that is involved at that level the more is oxygen poisoning likely to occur. Symptoms include dizziness, headache, muscle twitching, and convulsions with coma. This syndrome occurs mainly in the rebreathing units at the shallower levels but may occur in extremely deep dives with the use of air. For instance, at a depth of 297 ft. and an absolute pressure of 10 atmospheres, the use of compressed air or even a 20% oxygen mixture with helium will give the same oxygen partial pressure as using 100% oxygen at 33 ft. Therefore, symptoms below that level can be identical with oxygen poisoning. Oxygen tensions of air which is breathed in the cylinders used in the deep diving record attempts are almost always cut down to 10 to 8% or even, for low dives, 5%, in order to minimize the possibility of oxygen poisoning. The treatment is simply to come up from the depth at which symptoms begin, and they will decrease rapidly.

Drowning.—Drowning as a result of exhaustion, oxygen lack, and carbon dioxide excess is one of the most common sources of fatalities. Exhaustion is the keynote to this type of accident, and the development of the exhaustion would be markedly increased by panic in an emergency which could cause a diver to overextend himself and ignore completely the general principles of safe diving. The symptoms are unconsciousness, cyanosis, and vasomotor collapse. The treatment is immediate and enthusiastic artificial respiration, preferably with oxygen. The prophylaxis of drowning is to remember to have available under all circumstances and at all times as many of the safety precautions and equipment as possible. One of the most effective safety measures is some type of a float with a line on it at least three times as long as the planned diving depth, with a 2-lb. or 3-lb. anchor weight on the end. This float may be an innertube or a fancy arrangement on which one can hang spear guns, fish, abalone, abalone irons, and camera and thus have an efficient piece of equipment as well as a reliable, handy place to rest. There is no way of overemphasizing the importance of having somewhere to rest when one becomes overtired or has had a harrowing experience. Many men have had nearly fatal accidents, and it behooves all divers to use their heads and take advantage of such a simple and efficient piece of apparatus as a float.

Ruptured Eardrums.—The increased pressure at depth is a mechanism which forces the eardrum to go inward toward the middle ear unless there is equalizing pressure from the middle ear to prevent it. If the eustachian tubes are closed off and air is unable to reach the middle ear from the nose, a ruptured eardrum may occur. The symptoms are acute pain in the ear and, frequently, bleeding from the external canal. Treatment is prevention of infection and prohibition of diving until healing is complete, approximately a period of eight weeks. Without infection, complications, or a severe tear, a small rupture will heal promptly and normally without difficulty. Prophylaxis depends on having the eustachian tubes as open as possible and not diving unless they are open and kept that way. Ear plugs should not be used in diving as they would, if they fit tightly, cause a rupture of the drums from the inside as soon as the pressure in the middle ear reached the pressure of the water. The free exchange of pressure into and out of the external ear is just as essential as the exchange into the middle ear through the eustachian tubes. There is an associated condition in which a rubber suit, used for warmth, can flatten out over the external canal, sealing it completely.

If the negative pressure in the external canal with the pressure bowing the drum out from the middle ear is not quite strong enough to break the drum, a blood blister may occur from the suction effect. This blister can be quite large and rupture the skin of the external canal beside the drum, with bleeding from the ear. The prophylaxis is not diving with a severe cold or when for any reason the eustachian tubes are unable to allow the transfer of air back and forth freely. An easy way to test this is to hold the nose tightly and try to blow hard through the nose so that the intranasal pressure is increased. If there are stuffy feelings in both sides through both ears, then the eustachian tubes are open and will present no difficulty. Frequently the use of propylhexedrine (Benzedrex) or some other type of an inhalant to shrink the mucous membranes will give a good exchange where swollen membranes would cause difficulty.

"Squeeze."—The phenomenon known as "squeeze" is peculiar to the use of the dry suit, which is a solid rubber sheeting arrangement encasing the body, with elastic wrist bands and a stretchable opening for the face. Means of entry is a chute in the front of the chest, and this is closed off with rubber bands. Two or three sets of wool underwear are worn inside this rubber suit for warmth. Air entrapped in this underwear by the pressure of the water may cause folding of the

skin, and the skin may actually be sucked up into little ridges and welts in the folds of the cloth because of the relative negative pressure of some of the folded areas. The ridges and welts may approximate blood blisters and last for several days. The areas with the most air entrapped are those of the poorest fit of the rubber suit, especially the genital areas, and in a male diver squeeze may be quite noticeable. Also, air from the scuba unit may be forced into the suit by snorting into the face mask, causing an increase of the amount of air inside. This is all right at 100 ft., but during ascent this same air under pressure blows up the suit like a balloon; the rate of ascent can thus get out of control, so that it may be difficult for the diver to slow to the recommended rate of 25 ft. per minute. This does not happen with a wet suit, which allows water to get inside, thereby equalizing the pressure.

The same type of a squeeze may occur as a result of a tightly fitting face mask if the individual does not realize that he needs air from inside his nose to fill in the mask. Water pressure can compress the mask sharply around the nose, face, and eyes, causing negative pressure with protrusion of the eyeballs. For this reason, in any but the mildest and most shallow of diving, diving goggles are not recommended. They allow no method of putting air inside the goggles themselves when under pressure, and, therefore, eyeball squeeze is more frequent with goggles than with masks.

Comment

These, then, are some of the difficulties which can beset a diver. Diving is a tremendous sport, exciting, interesting, and different. But the sea is a hard taskmistress and she allows comparatively little human error. With adequate preparation and precautions, diving can be safe. Without them, accidents are likely and dangerous. It behooves everyone to be as careful as possible in taking up the wonderful sport of skin diving.

SURGICAL TREATMENT OF INJURIES TO LIGAMENTS OF THE KNEE

Don H. O'Donoghue, M.D., Oklahoma City

The most severe forms of injuries to the knee often do not properly heal without surgical intervention. This is true whenever any major ligament is completely cut across or avulsed from its attachment, and particularly when the torn ends of one structure come to lie in positions that hinder the union of other structures. Surgical experience with over 150 cases of injury to the knee has shown that conservative treatment can be expected to lead to healing only when tears are partial. When the symptoms of pain, instability, abnormal mobility, hemarthrosis, and circumarticular effusions testify to severe injury, conservative treatment fails. The best results in such cases have been obtained when diagnosis was precise and surgical treatment prompt. Surgery is followed, on the same day, by physical therapy, which includes muscle-setting exercises (isometric contraction without joint motion) and other graded activities. A policy of complete repair and conscientious rehabilitation has given increasingly gratifying results.

While we are not primarily concerned in this discussion with the over-all treatment of injuries to the ligaments of the knee, one cannot intelligently discuss surgical treatment of such injuries unless there is some generalized discussion of the proper indications for surgery as opposed to nonsurgical measures. I have repeatedly emphasized in previous reports the necessity for an extremely accurate diagnosis of an injury to the knee if one is to be prepared to carry out the ideal treatment.[1] If one assumes that surgical treatment is never indicated for injured knee ligaments, treatment of the injured knee becomes vastly simplified. If on the other hand one is prepared to admit that there are some cases which will require surgical treatment, it becomes immediately apparent that one must be able to determine which case should be treated by surgery and which case should be treated by nonsurgical methods. If all ligament injuries are to be treated by modifications of the same basic method, it may indeed be of only academic interest to try to determine the exact pathology which is present in any given case.

Read in the Symposium on Sports and Sports Injuries in the Session on Injury in Sports before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

I think there is a general agreement that there are certain basic therapeutic measures which should be instituted in the treatment of an injured knee ligament. Individual physicians may use many variations but, in general, aspiration, local injection, compression bandage, ice pack, immobilization, local heat, protection, and finally rehabilitation are utilized to a greater or lesser degree, depending on the severity of the injury and on the inclination of the physician. If all knee injuries are to be treated alike, it may be of little importance to determine the exact pathology, since one can play it more or less by ear and regulate the number and degree of the above measures he uses according to the response of the injury to treatment. This may be the easiest and most convenient way of treating it. The fly in the ointment, of course, is that this is not the best way of treatment.

If one could safely assume that treatment may be standardized into the measures mentioned above, the problem would become quite simple. If there is effusion, aspiration may be carried out. If the effusion recurs, aspiration may be repeated. If the effusion subsides, further aspiration will not be necessary. If the injury is mild, compression may well be the only protective appliance applied, and it may soon be discarded. On the other hand, if swelling persists, compression bandages may be continued over a longer period of time and vary from the elastic bandage to the application of a cotton cast. If symptoms do not subside promptly, more adequate treatment may be carried out to the extent of applying a plaster cast, which can be worn for several months if the knee does not respond. So, if treatment is to be identical whatever the degree of the injury and whatever the ligaments involved, one could well initiate this treatment first and then decide, depending on the patient's progress, whether he was badly hurt or had a minor injury. Why then should we demand "tender but meticulously complete examination of every injury"?

Such specious reasoning, by appearing on the surface reasonable, insidiously undermines one's actual understanding of the condition which he is treating. It is easy to see how the habit of treating these injuries by "feel" rather than by diagnosis becomes fixed. It you are called on to examine a knee injury and you respond by saying "pack in ice until morning," the next time the trainer or coach has to manage this injury he will "pack it in ice" himself. Indeed, if the treatment is to be standardized into such a pattern, he is perfectly correct to do so.

It has been shown through years of observation, however, that nonsurgical treatment is not always the best treatment. Among orthopedists there may be considerable difference of opinion as to just how often surgery is indicated and just how complete the surgery should be. But I know of no one, particularly one interested in the treatment of knee injuries, who would say that surgery is never indicated. It must be admitted, therefore, that surgery is indicated for certain types of injuries.

An objective study of results shows that surgery done early, within 10 to 14 days, is distinctly more favorable than surgery done at a later time.[1b] Careful investigation of many cases has shown that the most vital single factor governing the degree of recovery from a severe knee ligament injury is not the severity of the injury, the location of the tear, or the age of the patient; it is the time at which the operation is done.[1b] Almost without exception in this long series (over 100 cases), the patient who was operated on within two weeks obtained a better end-result than a comparable patient operated on at a later time or treated nonsurgically. The patient with a mild injury, for whom indecision and procrastination resulted in considerable delay before operation was done, obtained a much less perfect result than did the patient with a severe injury, for whom operation was done promptly. The very nature of the most severe injuries made decision to operate easy, and the operation was carried out immediately. These patients, in spite of the major injury, obtained excellent results, much better results than those obtained by patients who were less severely hurt, for whom the operative indication was not so clear and surgery was postponed or not carried out at all.

If we are prepared to concede, first, that there will be some cases in which surgery will be indicated and, second, that surgery is much more successful if done early, it must follow that the decision as to whether a patient is to be given surgical treatment must be based on early, thorough, careful examination, with the patient under anesthesia if necessary. All knee injuries must not be treated alike if the best results are to be obtained. Therefore, diagnostic procedures must be an integral part of any discussion of surgical treatment of ligament injuries.

The fact that a high proportion of these injuries occur in young athletes serves to emphasize the importance of the above statement. The athlete must have 100% recovery, or he is no longer an athlete. The athlete demands your best effort in order to preserve his athletic ability. By the same token, every patient should have this same major effort to restore him to normal.

The following precepts are a guide in the management of knee ligament injuries:

First, the goal must be complete recovery. Experience with many cases has emphasized the importance of this concept. If the immediate decision is that recovery cannot be complete and is not even worth attempting, it is obvious that it will not be complete. If we do not aim for 100% recovery, we certainly will not attain it.

Second, avoid expediency. Particularly in the athlete there are great pressures applied to avoid comprehensive treatment. The player is anxious to return to play, and the pressures of relatives and coaches that he continue competition are real. However, in the final analysis, a temporizing attitude satisfies no one. It is important that the physician decide what treatment should be done in a given case, then see that it is done.

Third, the best treatment rather than the most convenient must be selected. It must be important to the doctor to restore the patient's activity to the level he had before he was injured. If the patient wants to play football, this desire should be considered as an important one and not casually shrugged off. Once he realizes this, the player will cooperate fully with your recommendations. Bear in mind that his career is as important to him as yours is to you. Would you willingly give up your career in medicine if this could be avoided by more careful management? It is no more fair to expect him to give up his.

Fourth, treatment must be prompt. A definite decision as to proper treatment must be made at the earliest possible moment. Surgery must not be reserved for those cases where other methods have failed. Surgical treatment is a method to be chosen on its own merits and not backed into by failure of other methods.

Anatomy

The knee joint has no basic stability inherent in its bony structure. It has neither the ball and socket of the hip nor the mortise and tendon of the ankle. The slight bony stability that exists is due to the fact that the lower end of the femur is a bipod and so resists lateral motion without actual separation of one or the other condyle from the corresponding articular surface of the tibia (fig. 1 and 2). Essentially this stability is obtained by the complete investiture of ligaments which surrounds the joint and prevents separation of the femoral condyle from the tibial plateau. The medial and lateral collateral ligaments which become continuous with the posterior ligament behind and the patellar retinaculum in front serve to give this added stability. The posterior ligament which is tight only in complete extension prevents hyperextension of the knee and supports lateral stability when the knee is in complete extension. In order to permit flexion of the knee, the anterior ligament is attached to the quadriceps' mechanism, which permits motion under constant tension. The thickening of the ligamentous structures which make up the medial and lateral collaterals serves to give lateral stability. The anterior and posterior cruciates prevent anteroposterior displacement of the tibia on the femur. Each of these ligaments has its essential function and the function of each is supplemented by the other ligaments. The integrity of the knee is entirely due to the ligamentous support which it receives. Hence a ligament injury is doubly significant in the knee since the osseous portion of the joint does have so little inherent stability.

The cause of a sprain is an abnormal motion of the joint which throws a stress on the ligament designed to prevent this motion. Forcing motion beyond its normal limit will result in some degree of injury to the ligament primarily involved. In the knee joint, this motion may be in any direction; adduction or abduction, overextension, internal or external rotation, forward or backward displacement, or almost any combination of these, although certain particular combinations are much more frequent. Much depends on an accurate diagnosis of the nature of the injury. Knowing the manner of injury certainly can give a lead as to the type of ligament damage to be expected. In one classic injury, the foot is fixed to the ground, the thigh rotates inward and the leg outward; the knee is forced inward toward the opposite leg and the stress is primarily received on the ligaments on the inner side of the knee (fig. 3 and 4). This is by far the most common type of the athletic injury of the knee. Using this type as an example, what may we expect in the way of injury, provided it is known that this accident occurred by the familiar lateral blocking (fig. 3) or by the "cut back" motion of the running athlete? As the foot is forced into external rotation, stress comes against the medial collateral ligament of the knee, the superficial layer of which takes the strain first. As this stretches, tears, or gives way, the force reaches the deep layer, to which is attached the medial meniscus. If the force continues, the anterior cruciate receives the stress and it too may give way, and in severe injuries the posterior cruciate may also rupture. These injuries are shown in the accompanying illustrations. Obviously, the injury may stop at any point in this progression of events. In a similar manner, adduction or internal rotation puts the force against the lateral ligament of the knee, the lateral cartilage, and the anterior and posterior cruciate. So also hyperextension at the knee throws initial stress on the posterior ligament of the joint, followed by stress against the posterior cruciate ligament and the cartilages. Direct forward motion of the tibia on the femur will injure the anterior cruciate, while the opposite force will damage the posterior cruciate.

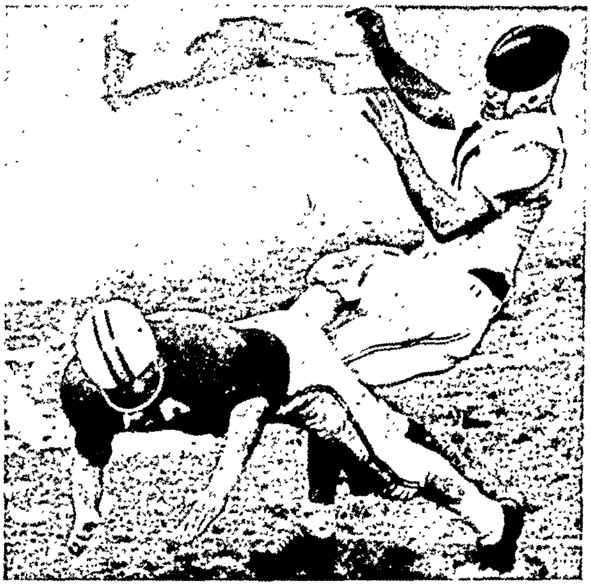

Fig. 3.—Note force applied to lateral side of knee. Cleats are fixed to ground, leg is forced into external rotation and abduction; knee opens up on medial side and tibia is forced forward in relation to femur, tension being placed on medial collateral and anterior cruciate ligaments.

Diagnosis

To consider the diagnosis of injury to the joint, what are the important factors? First a general evaluation of the situation: Did it seem to be a serious injury? Was the player immediately disabled, or was he able to keep going? Did he feel that he had a serious injury? Was he able to come off the field under his own power, or was he carried? Was he suffering extreme pain, or was it relatively mild? After this evaluation, an early, careful, and complete physical examination of the joint is of major importance. The earlier this can be done the better, since often elements can be noted early which become obscure after pain and swelling screen the symptoms. Note whether tenderness is at the joint line, above the joint, or below. Check the knee carefully for abnormal mobility in all directions, including rotation, lateral motion, and anterior and posterior motion. Observe the degree and rapidity of the swelling. Investigate whether the knee was actually locked at the time of injury or whether it is actually locked at the time of the examination. All of these things are of extreme importance if they are done in the early stage before pain, swelling, and apprehension become factors. Often, in this initial examination, a definitive diagnosis as to the location and extent of ligament injury can be made.

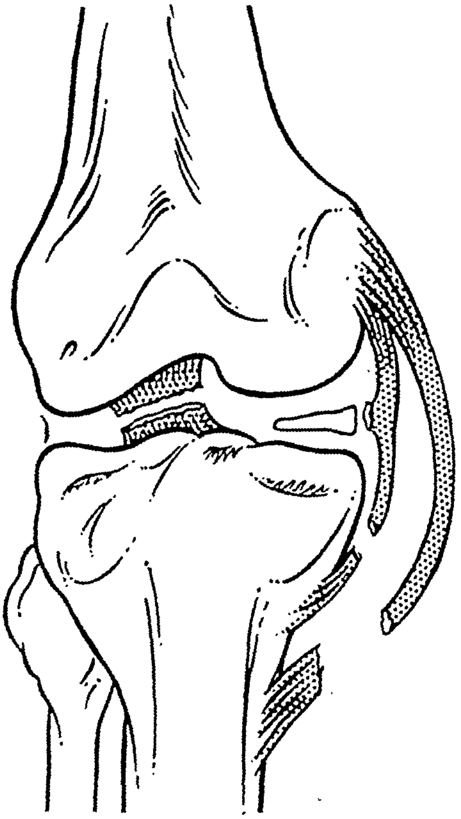

Fig. 4.—Classic injury resulting from forces shown in figure 3. Note superficial layer and deep layer of medial collateral ligament torn near tibial attachment. Medial meniscus is ruptured and anterior cruciate ligament has torn completely.

The injury must be classified as to severity as well as location. The simplest classification of knee ligament injuries is into three divisions: mild, moderate, and severe.

Mild Injury.—In a mild ligament injury, we postulate that there has been some damage in the ligament but that its strength has not been materially impaired. The symptoms of such an injury are tenderness at the site of the tear; pain on active use of the knee; local swelling at the site of the injury; pain on forced motion or attempt to duplicate the motion which caused the damage. The negative findings which are important in diagnosis of a mild injury would be no instability, no blood in the joint, no effusion in the joint, no locking of the joint, and no pain on ordinary motion of the joint.

Provided that determination can be made that it is a mild injury, treatment can be based on the premise that the ligament is actually intact. This type of ligament injury where prolonged and extensive treatment is not necessary fortunately includes the great bulk of ligament injuries. The basis of treatment is (*a*) protection against further injury and (*b*) relief of local symptoms by injection into the involved ligament some of the various substances such as procaine, hyaluronidase, or hydrocortisone. With this injury, activity can be resumed at once or at least relatively soon, but active sports should not be permitted immediately after local anesthesia. Complete immobilization is neither necessary nor desirable. The patient may be rapidly rehabilitated without danger.

Moderate Injury.—In the second group, the moderate ligament injuries, it is considered that the ligament has been partially torn, rather than just having had a few fibers of the ligament pulled apart or separated. A certain definite portion of the ligament has been damaged and its strength impaired. It may be 10 to 90% ruptured. The symptoms here are similar to those of the mild injury only greater in degree. Each of these groups shades imperceptibly into the other. The positive findings are pain in the knee; tenderness at the site of the injury; disability of a greater degree than in the mild type; swelling at first localized at the area of damage, followed by swelling diffusely about the joint; fluid or blood in the joint; pain or reproduction of the force and direction of the injury; and possibly locking due to cartilage damage. There is no abnormal motion either laterally or in anteroposterior displacement of tibia on femur. Findings indicating complete avulsion of a ligament should not be present if the damage to the ligament is only partial.

The treatment of moderate sprain is based on the premise that there has actually been significant damage to the ligament with weakening of its structure and considerable loss, or at least potential loss, of function. Therefore, it must be more comprehensive than in the mild group. Treatment consists of rest, local injection, compression bandage, cold pack early, followed by heat, later protection by splints, pressure dressing, and aspiration of the joint. This must be followed by a period of rehabilitation, the rehabilitation being necessary since there is a required period of immobilization during the course of treatment. In rehabilitation, active physical therapy, increasing active use, protective strapping, and reeducation are all of considerable importance. This group of ligament injuries is the one where injudicious overuse or too early return to physical activity may make the difference as to whether or not recovery is prompt and complete. Reduction of pain and swelling by local injection must not be permitted to cover up the true nature of the injury since active stress must not be allowed until healing is complete. Ordinarily recovery should be expected, with no residual disability in the joint. By far the major number of knee ligament injuries will fall in the first and second groups.

Severe Injuries.—In consideration of the third group, the severe ligament injuries, diagnosis is based on the premise that one or more of the major ligaments of the knee is completely torn loose from its attachment, or torn through its substance. The mechanism of this injury is that previously mentioned, namely, forcing the knee through a wide range of abnormal motion beyond the tolerance of the ligament. The symptoms in this type of injury are much more severe. Examination and evaluation reveal immediate disability; giving away of the knee joint; severe pain in the knee and leg; definite abnormal motion (may be rotatory, lateral, or anteroposterior); instability of the knee joint; blood in the joint; blood infiltrating through the tissues; local swelling first at the site of injury and very rapidly into the knee itself; locking, which may or may not be present; and confirmatory x-rays showing abnormal lateral motion at the knee joint (fig. 5).

The treatment of this serious type of ligament injury is extremely important and this is the field where there has been some difference of opinion as to the best measures to be employed. Fortunately, this type of injury is not common, but, when it does happen, it can be disabling to the point where the athletic career is abruptly terminated.

If at all possible the diagnosis must be made at once. If one waits three or four weeks until swelling and pain subside instability becomes quite obvious. The optimum time for treatment has passed. Diagnosis must be early and definitive in order to permit the proper decision as to treatment.

Once the diagnosis of a complete ligament tear has been made the method of treatment must be elected. It will not suffice to try so-called conservative treatment first and then proceed to surgery. Early repair yields so much better and surer results than late repair or reconstruction that surgery must not be reserved for those cases in which conservative treatment has failed. Modern anesthesia, operating room asepsis, highly skilled personnel, and antibiotics have minimized the hazards to the degree that in the well-run hospital with a competent surgical team, open surgery can confidently take its place alongside nonsurgical measures. In the absence of complicating factors the management chosen must be that method which will give the highest percentage of the most complete recovery and in the shortest time.

I believe that if one can demonstrate complete severance of any single ligament or of any combination of ligaments of the knee surgical repair is mandatory. The repair should include not only one ligament but all ligaments involved. It makes little sense to go to the trouble of repairing the collateral ligament and ignore the cruciate because it "adds to the severity of the operation" or is "too difficult" or "may not be essential." The cruciates are not vestigial. One has only to examine the splendid mechanism of the anterior cruciate, to note its size, to check its strength, and to recognize its vital structure in order to realize that this is not an evolutionary misfit ready for the discard. The cruciates play a living vibrant part in that ingenious mechanism that is the knee. We may argue about their exact function but be assured they have a major one.

Even though we agree that the knee has many interlocking ligaments and that it acts as a physiological unit and that it may spare some portion of that unit without disaster, the very fact that the cruciate is one of those factors means that the knee is actually or potentially less than normal without it. The cruciate should be repaired since in no other way may a normal knee joint be attained.

I examine many knees in which the only detectable complaint is cruciate instability. These patients seek treatment because to them the condition is materially disabling. This in itself is evidence that the cruciate in a given case may be vital for adequate function.

Late cruciate reconstruction is highly speculative and should be done only when the stakes are high, as, for example, a professional baseball player who is unable to play because of anteroposterior instability. Early cruciate repair is highly successful and should be done as a matter of course. It is not unduly technical and any competent orthopedist can do it if he properly prepares himself in the necessary technique.

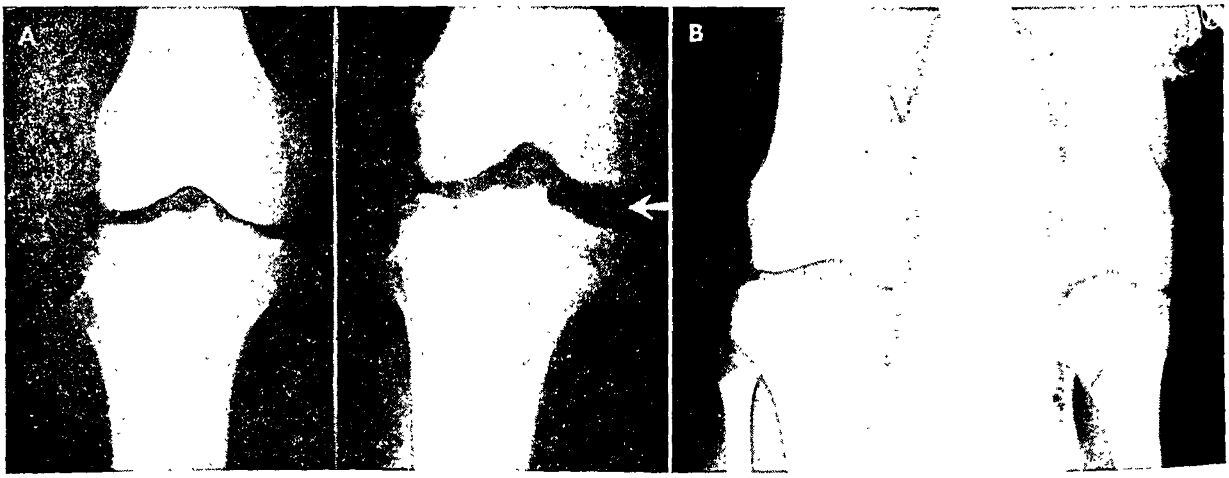

Fig. 5.—*A*, x-ray of injury to medial collateral ligament of knee: *left*, normal anteroposterior view; *right*, position of abduction of leg on thigh; arrow indicates increased tibio-femoral point space. *B*, x-ray illustrating damage to lateral collateral ligament: *left*, straight anteroposterior view of knee; *right*, with leg adducted on thigh.

In certain cases the ligament may repair spontaneously, especially the collateral ligaments. The danger is in our inability to determine short of surgery which case will heal with normal length and which will not. I have actually found at surgery the tibial end of the medial collateral lying in the joint on top of the medial meniscus (fig. 6). I have seen the ligament torn with the ends free and the tendon retracted an inch or more (fig. 7). I have located the femoral attachment of the medial collateral ligament lying in the joint on top of the meniscus (fig. 8) with the femoral end of the posterior cruciate lying over the medial meniscus. There are many other such situations which are unredeemable except by surgery. With such pathology actually seen, one becomes very skeptical of uniformly good results reported from nonsurgical treatment.

What about results of surgery? After a survey[1b] of 80 consecutive cases of ligament injuries the findings showed that, regardless of the severity of the injury, early repair gave approximately 90% of good results (over 90% in athletes). The time and the completeness of repair were much more important than the nature or severity of the injury. Failure of the cruciate repair was the biggest single cause of permanent disability in knee ligament injuries. Repair of the cruciate was highly successful early but very unpredictable late.

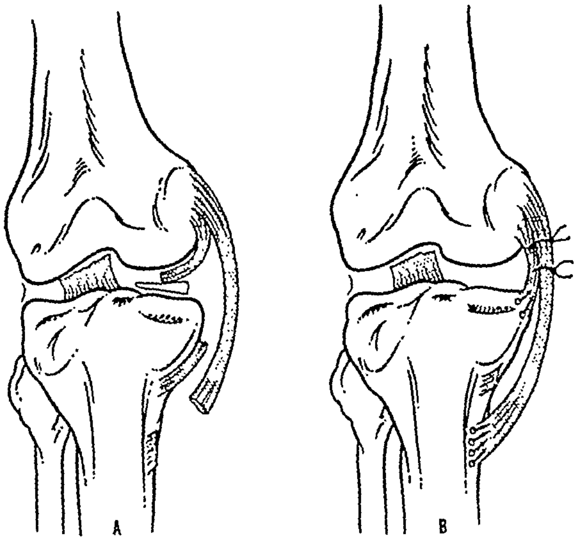

Fig. 6.—Injury from rotation-abduction force, before (*A*) and after (*B*) repair. Note deep layer of medial collateral ligament torn from tibial rim and from cartilage and lying on top of cartilage, requiring surgery for deep layer to be repaired. Note femoral attachment of anterior cruciate avulsed and widely separated.

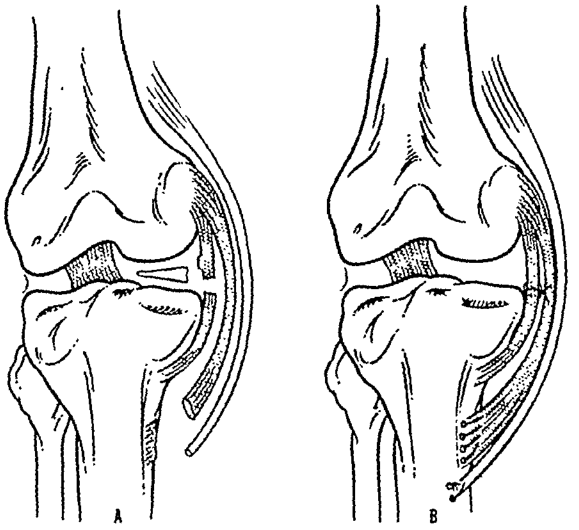

Fig. 7.—Classic injury of semitendinosus tendon attachment pulled loose, with wide separation of ligament attachment, before (*A*) and after (*B*) repair.

Bennett[2] lists four musts for the surgical treatment of knee ligament injuries: 1. The patient must be seen early. 2. The surgeon must be a good diagnostician and able to identify ligament injuries. 3. The surgeon must have good judgment. 4. The surgeon must be competent. Certainly these are not unattainable goals for the present-day well-trained orthopedist.

Management of Severe Ligament Injury

Let us consider the actual management of a severe ligament injury. In diagnosis, much depends on patient cooperation, so gentle hands are an asset indeed. Usually one finds immediate disability, often severe, knee "giving away," severe pain, blood infiltration with or without blood in the joint, "doughy" swelling, tenderness, diffuse with local areas of increased tenderness corresponding to the location of the tear or tears. Above all, one finds instability corresponding to the ligament involved. In order to determine this instability the good knee is examined first and a base obtained. Each motion in the injured knee is carefully compared with that of its fellow. The knee is checked in complete extension for adduction and abduction; then flexed to 150 degrees and abduction, adduction, and internal and external rotation are tested; then flexed to 90 degrees so the drawer sign cannot be elicited.

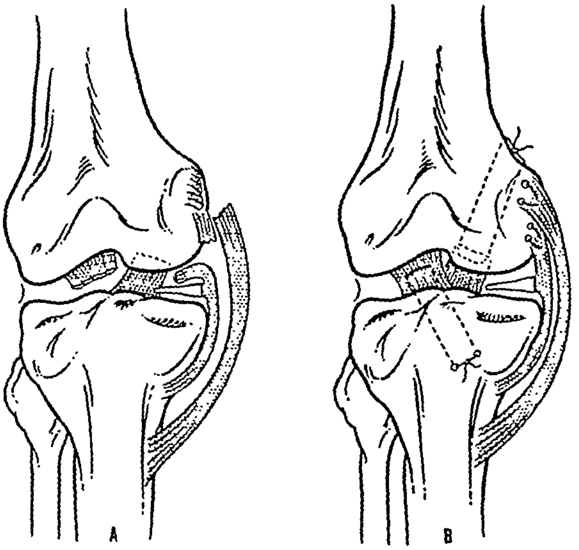

Fig. 8.—External rotation-abduction injury, before (*A*) and after (*B*) repair. Note tibial attachment of anterior cruciate torn loose and separated; femoral attachment of posterior cruciate pulled away; both layers of medial collateral ligament torn away from femoral condyle; deep layer folding inward and lying on top of cartilage. Note anterior cruciate was fastened to tibia, posterior cruciate fastened to femur. Medial collateral was pulled away from joint and attached to femur.

Twenty-five per cent of my cases of cruciate severance were not definitely diagnosed before anesthesia.[1b] After this careful examination, decision is made as to the treatment. If one can demonstrate complete severance of any ligament, surgery is advised. The exact details of surgery for repair of various ligaments to the knee have been thoroughly described elsewhere and need not be repeated here. The thing with which I am vitally concerned in this discussion is the indication for surgery, not the technique. After surgery, a heavy posterior long leg plaster splint is applied, care being taken to support the extremity by the foot and thigh, rather than beneath the calf, in order to avoid stress on the anterior cruciate ligament due to lifting the tibia forward on the femur. After this first splint has set a lateral stirrup is applied.

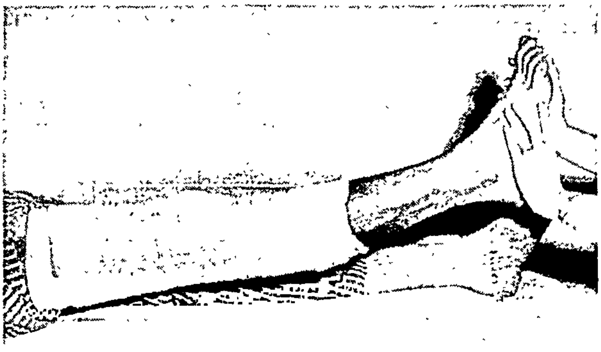

Fig. 9.—Completed cotton cast, splint being pressure bandage consisting of multiple layers of sheet wadding followed by yucca board for stability. See Campbell's "Operative Orthopedics" (edited by J. S. Speed, ed. 3, St. Louis, C. V. Mosby Company, 1956, vol. 1, p. 88) for complete details.

After the patient has returned to bed, the leg is elevated on pillows or a sling and carefully watched for circulatory impairment. The dressing is split before tightness becomes a problem and tightened up as the swelling subsides. At two weeks, this splint is carefully removed and again care is taken in the case of the anterior cruciate repair to support the extremity by the thigh and foot and not by the calf. Stitches are removed. The knee may be aspirated and hydrocortisone (Hydrocortone) or prednisolone (Hydeltra) injected if indicated by the presence of the effusion. This is not ordinarily necessary.

A very light weight long leg plaster cast is then applied with the knee fixed at 160 degrees. Frequently a walking heel is used if the repair seems stable and the patient is reasonably agile. He may use the heel for weight-bearing but is advised to continue use of crutches. At the end of two weeks in the solid cast, four weeks postoperatively, this cast is removed and a cotton cast (yucca boards over sheet wadding) applied (fig. 9). Aspiration and injection are repeated if indicated. This splint is removed in two weeks (six weeks postoperatively) and an elastic bandage utilized as indicated. If effusion persists, repeated aspirations and injection may be necessary. This is not usually necessary. Most cases do not require even one aspiration.

For rehabilitation, quadriceps setting and straight leg raising of both legs are encouraged from the first day. Patient is in a wheel chair 24 to 48 hours postoperatively. He should be able to raise the leg actively, splint and all, by 48 hours, and to walk on crutches in three to five days. Weight-bearing is not permitted, however. After the solid cast is applied (two weeks postoperatively) the patient may walk with crutches on a walking heel if progress is good. He is permitted to discard his crutches if he feels able to walk around the house without them, but in general he should use his crutches while away from home. Meantime exercise of all other available muscles is encouraged.

After he goes into the cotton cast (four weeks postoperatively), he is urged to walk, preferably without his crutches, and to continue his exercises. At six weeks the cotton cast is removed and quadriceps rehabilitation begins in earnest (see table) and continues until the circumference of both thighs is equal. Specific written instructions with definite exercises are important. The actual level of activity varies much with the individual patient. The agile, wiry type of person, relatively light weight, may be allowed more freedom than the heavy lumbering giant whose ligaments are normally relaxed in all his joints. Running is permitted as desired if synovitis permits. No contact sport is allowed until four months, and not then if the quadriceps is not completely rehabilitated.

Rehabilitative Exercises to the Quadriceps Muscle After Knee Injury or Operation

Sit on the side of the table with the legs hanging over in a vertical position.

Raise the foot on the involved side to the horizontal position slowly to the count of 3 seconds.

Hold in horizontal position to the count of 3 seconds.

Lower slowly to the count of 3 seconds.

Rest for the count of 3 seconds.

Repeat this 10 times. Rest a little.

Do this through 3 series of 10 times each, i.e., 30 times total.

These exercises should be repeated two or three times a day depending on tolerance.

When able to complete the series of 30 elevations, add weight to the foot at the next period of exercise increasing its use until it can be used the full 30 times.

Continue these exercises, adding weight successively according to tolerance until possible to raise 25 or 30 lb. through this series. Use opposite knee for control to get some idea of how much weight injured leg should be expected to raise.

Make a chart for daily progress and record on it each period of treatment, noting the ascending curve of weight-lifting capacity.

Continue exercises until circumference of involved thigh is same as uninjured thigh and until injured leg is able to raise as much weight as uninvolved side. As strength increases, these exercises can be supplemented by other exercises, such as going up and down stairs, partial knee bends, single knee bends.

Naturally, each case must be strictly individualized both as to type of repair used and as to postoperative management. A patient with a good tight repair with strong ligament fibers can be permitted more liberty. Some patients need to be pushed in their rehabilitation (for example compensation cases and females). Other cases must be held down (for example 16 to 18-year-old athletes). The elastic bandage should be discarded early in the timorous and retained as a reminder in the overbold. If effusion persists, the usual treatment is followed: aspiration, repeated as required with injection of hydrocortisone, and use of elastic bandage as long as effusion is notable.

Such a regimen carefully followed with early examination, prompt decision, and complete repair of all torn ligaments, followed by conscientious rehabilitation, will give increasingly gratifying results in treatment of major injuries to the ligaments of the knee.

In my series of over 150 cases, 80% were under 25 years of age and 55% under 20 years of age. Since so many of these cases occur in young people, one must be particularly on the alert to try to reach the goal of the best recovery of function in the shortest time.

MANAGEMENT OF ANKLE INJURIES SUSTAINED IN SPORTS

Thomas B. Quigley, M.D., Boston

Inexact diagnosis and inappropriate treatment of ankle injuries can lead to serious disability. Decisions regarding them should be left to a physician whose authority should not be questioned. The patterns of fracture of the malleoli as seen in anteroposterior roentgenograms can give valuable information about concomitant rupture or avulsion of ligaments. If advantage is taken of the 20 to 30 minutes after injury before edema, hemorrhage, and spasm occur, closed reduction of even grossly displaced fractures can sometimes be accomplished with almost no discomfort. If roentgenograms indicate that soft tissues are ruptured or trapped between bony parts, prompt surgical correction is indicated. Cold, compression, rest, and elevation are the four basic elements of treatment for minor injuries. There is no justification for the use of procaine as an immediate therapeutic agent in any athletic injury. Operation was necessary in the case here described, but active motion without weight-bearing was started at 3 weeks, weight-bearing was permitted at 15 weeks, and skiing was resumed at 18 weeks after the injury.

The doctor who assumes responsibility for a group of athletes is in a unique position to study trauma. Circumstances are ideal for observation of injury from the moment of occurrence to full recovery. In sports involving quick pivoting on a fixed foot, such as football, soccer, and basketball, or unanticipated wrenching with a lever as in skiing, a high proportion of these injuries will involve the ankle.

The incidence of injury can, of course, be reduced by physical conditioning and the acquisition of skill in the techniques of the sport. It is a truism that the outstanding athlete is rarely injured, and then only under unusual circumstances. But not all participants in active sports are neuromusculoskeletal geniuses, nor do they have the time to become technical virtuosos.

For these, a considerable measure of protection is afforded by regular use of ankle wraps.[1] Applied over the inner of two pairs of socks, with a turn around the heel (fig. 1), these nonelastic bindings, which the player applies himself, effectively limit lateral mobility without interfering with flexion or

Read in the Symposium on Sports and Sports Injuries in the Session on Injury in Sports before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

extension. When required of all players at all practice sessions and games, the incidence of ankle injuries can be reduced at least 50%.[2]

Despite conditioning, ankle wraps, and skillful coaching, ankle injuries still occur, and the doctor's duty begins at the moment of injury. He should himself go on the playing field and decide whether the injured player should continue play or leave the game, and, if he leaves, whether he should walk or be carried. To leave such decisions to a coach or trainer is to gamble with future disability with the cards stacked against the player. The doctor's authority in these and other medical matters should be absolute and unquestioned. Practically all coaches today are quite happy to be relieved of this responsibility. They have enough difficult decisions in their own field.

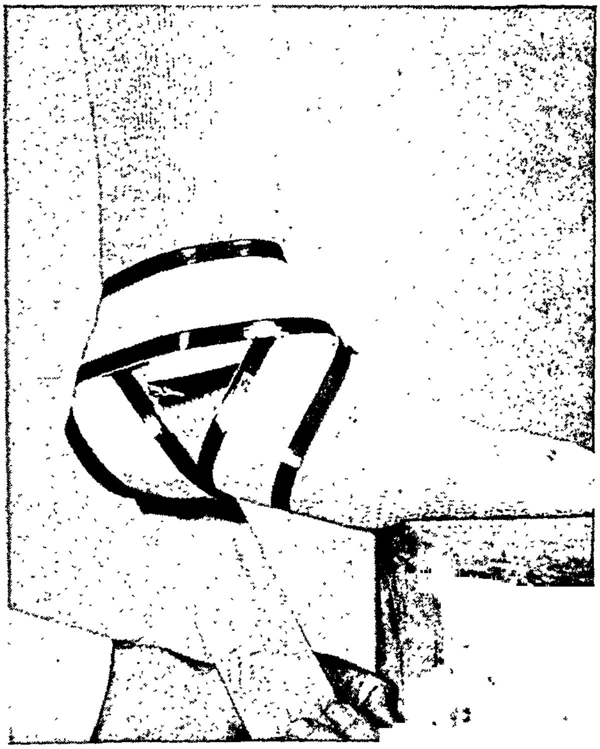

Fig. 1.—Nonelastic protective ankle wrap in process of application. Edges of wrap have been darkened to show basic turns of bandage. Turns around heel limit lateral mobility without interfering with flexion and extension.

Once off the playing field a preliminary survey can be made. All that can be accomplished at this time is differentiation between major and minor injury. Minor injury means sprain or incomplete rupture of ligament; major injury means fracture, complete rupture of ligament, or both. Almost invariably, anteroposterior and lateral x-rays will be necessary. Even the most experienced examiner cannot be certain of the presence or absence of fracture or widened joint mortise by examination alone. It is better to take 50 negative x-rays than to miss one serious injury.

Accumulated evidence from observation of the mechanism of the injury as it occurred, the location of pain, tenderness, and swelling on examination, the type of fracture, and the state of the joint mortise from the x-ray should be enough to establish a precise diagnosis of major bone and ligament injury. Fracture is, of course, obvious in the x-ray films, but the diagnosis of complete ligament rupture can be more subtle and, if not recognized, can be at least as serious as fracture in terms of future disability. For practical purposes, only three ligament complexes need be considered: the medial collateral (or deltoid), the tibiofibular-fibulotalar, and the lateral collateral (or fibulocalcaneal).

Most severe ankle injuries sustained in sport are of the abduction–external rotation type, in which the talus twists and pries the fibula from the tibia. Either the fibula itself fractures or the anterior tibiofibular ligament ruptures, producing widening of the tibiofibular syndesmosis (fig. 2). In either event, as force continues, the deltoid ligament gives way (or, more rarely in young men, pieces of the medial malleolus of varying size are avulsed) and the joint space between the talus and the medial malleolus can be seen to be wider than the horizontal component of the ankle joint.

Fracture accompanies ligament rupture more often than not, and the type of fracture, as Lauge-Hansen[3] has pointed out, is a most valuable key to diagnosis. Internal rotation-adduction forces can stretch only the fibular collateral ligament, the others being compressed, and then only if the characteristic horizontal avulsion fracture of the lateral malleolus does not occur (fig. 3). Isolated injuries to this fibulocalcaneal ligament, even when severe, only rarely require primary open surgical repair.

Analysis of ankle injuries sustained in sport should not require much time, and often advantage can be taken of the 20 to 30 minutes after injury, before edema, hemorrhage, and spasm occur, during which nature imposes analgesia, to accomplish closed reduction of even grossly displaced fractures with almost no discomfort.

For external rotation-abduction injuries in which the medial malleolus is intact, the simple device of suspending the stockinette-encased limb has proved most helpful (fig. 4). With the gastrocnemius relaxed by flexion of the knee, the ankle naturally falls into adduction, moderate flexion, and supination, reversing the mechanism of injury. Often little or no manipulation is required to achieve excellent reduction of grossly displaced fracture (fig. 5). Doughnuts of felt or foam rubber are applied over the malleoli and held with sheet wadding before plaster is applied. Most ankle injuries of such severity as to require splinting should be immobilized in a cast extending to the groin with the knee flexed 30-40 degrees.

Another set of x-rays is taken as soon as the plaster has set. If widening of the joint mortise is still present, it can be assumed that avulsed ligament is trapped either between the talus and the medial malleolus, in the tibiofibular syndesmosis, or both and prompt surgical correction is indicated.

Report of a Case

A 25-year-old student sustained a severe external rotation injury to the right ankle while skiing (fig. 6). Closed manipulation without anesthesia and application of a long leg plaster cast was carried out within an hour of injury. Films taken on his return to Boston five days later showed widening of the space between the talus and the medial malleolus and a high fracture of the fibula. At operation, a week after injury, the deltoid ligament was found avulsed from the medial malleolus and trapped in the ankle joint. The anterior and posterior tibiofibular ligaments were completely torn. Clot was removed from the tibiofibular syndesmosis, the deltoid ligament was sutured in proper position, and the tibia and fibula were bolted together. Active motion without weight-bearing was started three weeks after operation. The bolt was removed and weight-bearing permitted three months later. The patient skied again four and one-half months after injury.

Displaced bimalleolar or trimalleolar fractures in young athletes almost always require operation. Precise closed reduction is difficult, since no fixed point remains on which to hinge manipulation, and interposed soft tissue between the fragments of the medial malleolus is the rule rather than the exception. Little less than anatomic perfection can be accepted in these severe multiple ligament and bone injuries since these young men have at least five decades of use of their ankles ahead of them. Only the most trivial fractures, not involving ligaments, can safely be treated by a short leg boot and weight-bearing device.[4] Torsion within a walking boot can displace even the common, and usually uncomplicated, external rotation fracture of

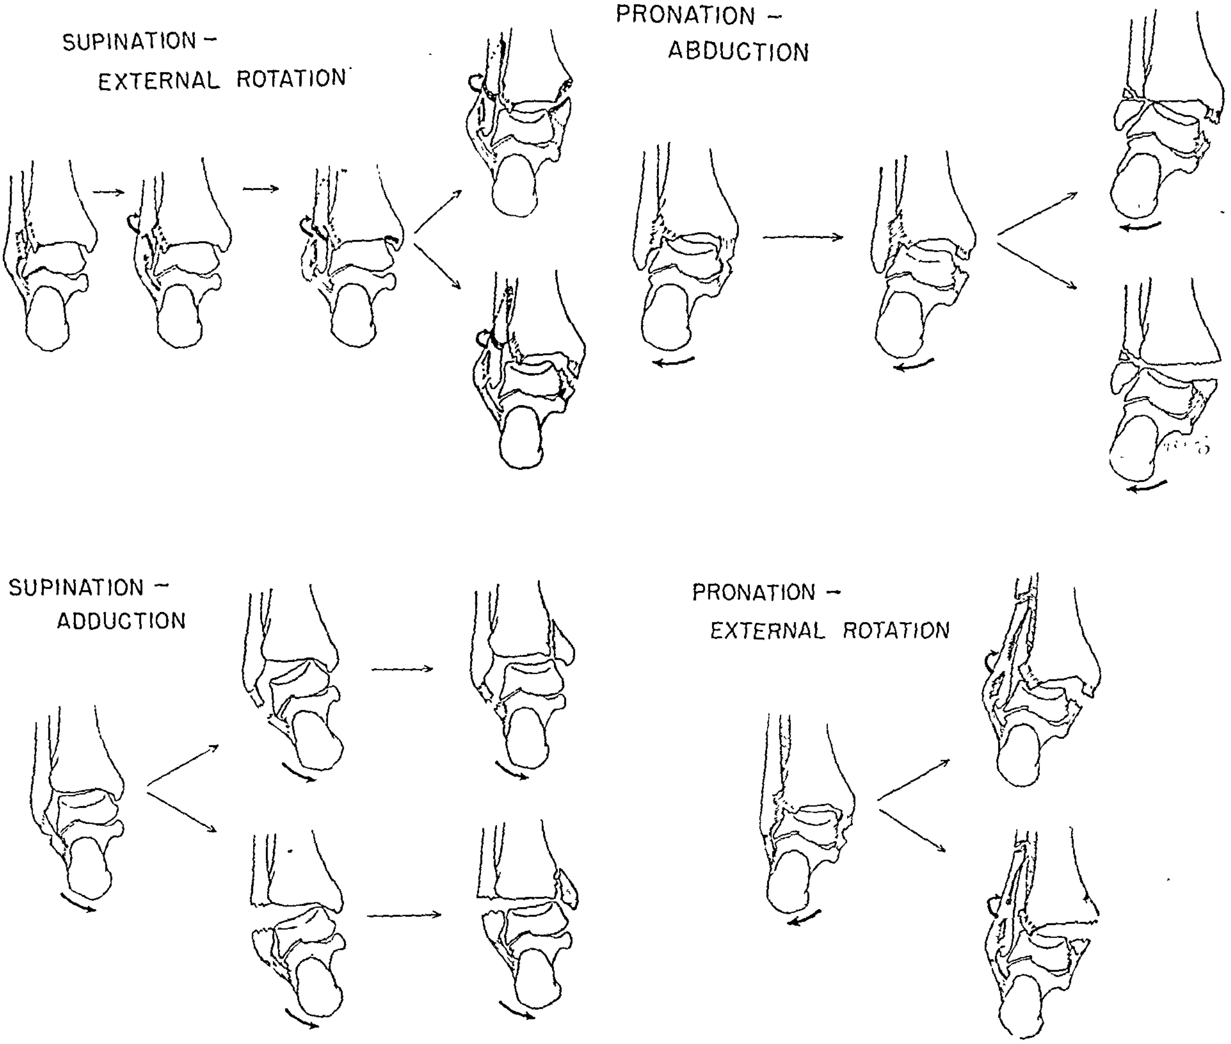

Fig. 2.—Patterns of ankle injury (after Lauge-Hansen[3]). Combinations of forces can occur but are uncommon. Fibula fracture in pronation-external rotation injuries can be in upper half of bone.

the distal fibula, since concomitant injury to the deltoid ligament can be more severe than originally appreciated.

If, at the first examination, within moments of injury, the damage is found to be minor, four principles of treatment are instituted—cold, compression, rest, and elevation. These are based on the concept that a sprain is a partial tear of a ligament, with hemorrhage at the point of tear, absorption of the resulting hematoma, and replacement of the gap by fibroblastic scar. The process is the same as the healing of any sterile wound. No method has yet been found to accelerate the process beyond nature's rate, but many are available which slow it down or disturb the end result. These include the use of procaine hydrochloride (Novocain), hydrocortisone, rough manipulation and massage, and "running it out." Cold, promptly applied, constricts the arteriolar bed and limits the hematoma. Compression disseminates the hematoma already present and speeds its absorption by

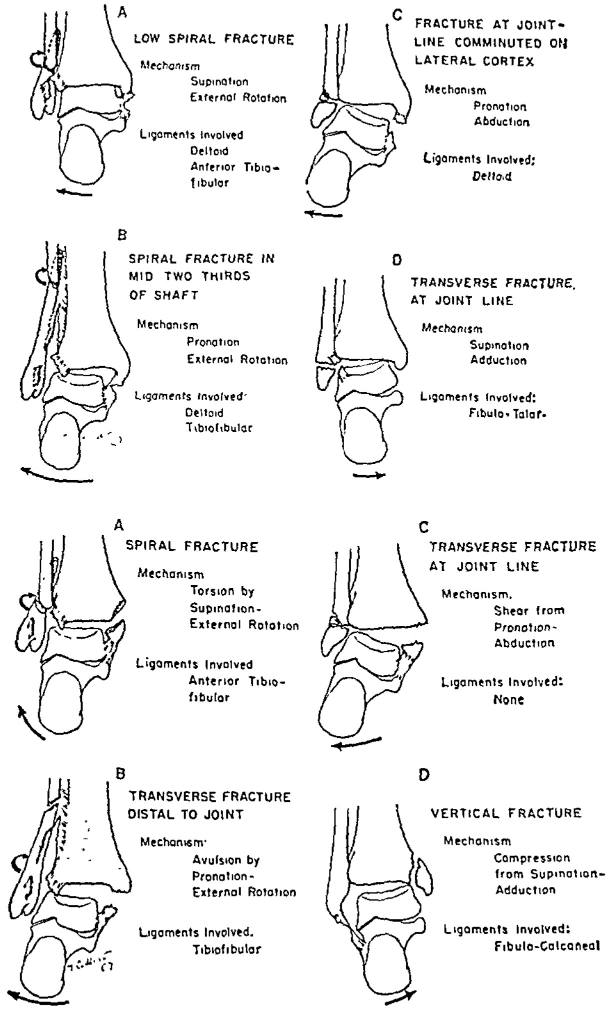

Fig. 3.—Key to analysis of ankle injuries: *top*, fibular; *bottom*, medial malleolar.

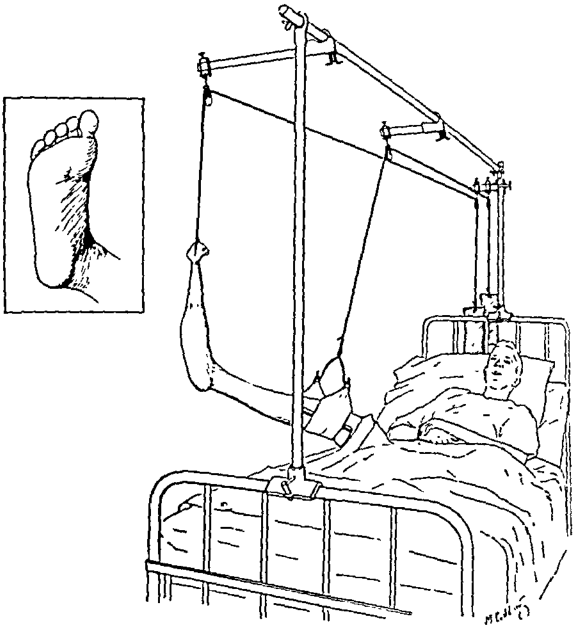

Fig. 4.—Stockinette suspension for external rotation-abduction fractures and ligament avulsions. Foot and ankle naturally fall into position which is opposite of forces producing injury. Reduction is often effected without further manipulation.

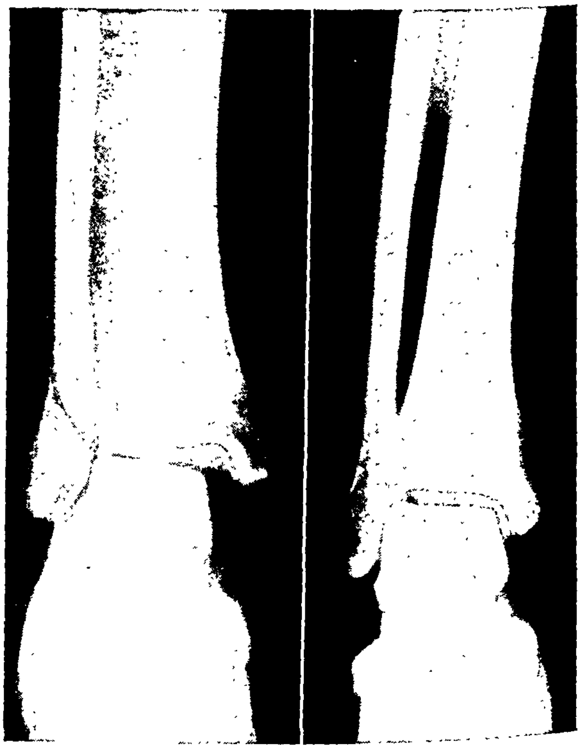

Fig. 5.—Supination-external rotation fracture of fibula with rupture of deltoid ligament before and after 12 hours' suspension in stockinette (fig. 4). Medial side of ankle was explored. Deltoid ligament was found avulsed from its distal attachment and rolled on itself but not trapped in joint.

increasing its surface area (fig. 7). Rest is obvious. As in any injury, whatever motion hurts is wrong, whatever does not hurt is right. Elevation minimizes the edema of dependency and disuse. At this first examination, when the injury has been determined to be a sprain and not a ligament rupture or fracture, a bevelled doughnut of foam rubber, of the tan open-cell type, 2.0 cm. in thickness, is placed over the injured side of the ankle with the malleolus in the aperture. The skin is protected from direct contact with the rubber by sheet wadding. The rubber is then compressed to about half its thickness with an elastic cotton bandage, extending from the toes to the upper calf. The limb is then immersed in cold water (40 degrees) or packed in ice bags for 30 minutes. The wet dressing is then replaced, crutches are fitted, and the patient is instructed in their use. He is advised to spend as much time as possible during the next 24 hours with the ankle elevated above the level of the heart.

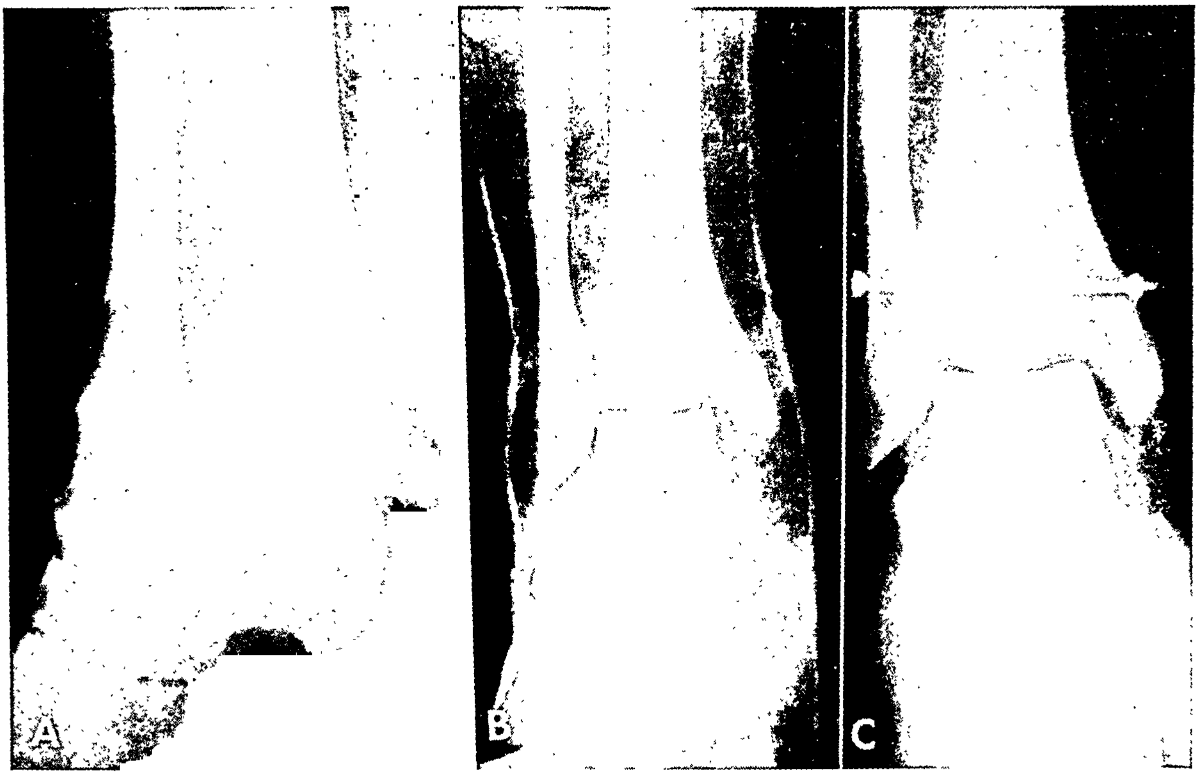

Fig. 6 (reported case).—*A*, film taken immediately after severe external rotation injury sustained in skiing. *B*, film taken five days after immediate closed reduction. Space between talus and medial malleolus is twice as wide as normal. *C*, postoperative film. Trapped deltoid ligament has been removed from joint, and joint mortise has been restored by bolt, which was removed three months later.

At the second examination, 24 hours after injury, edema should be minimal, ecchymosis may already have appeared at the periphery of the foam rubber pad, and by gentle palpation and manipulation an accurate analysis of the particular ligaments involved and their degree of involvement can be made. It is convenient to grade the severity of sprain from 1 to 4, 1 being the least degree of injury which can be classified as sprain and 4, complete rupture. Such classification is of help in prognosis, a matter of great importance to most athletes and coaches. The majority of sprains fall into grades 2 and 3. Experience during the past 70 years at the Harvard department of athletics has established that the commonest ankle injury, a grade 2 sprain of the anterior tibiofibular and fibulotalar ligaments, treated properly, with full cooperation from the patient-player, will be sufficiently healed in 8.2 days to permit full participation in contact sport. It has become equally clear over these seven decades that any prognosis ventured before the second examination, 24 hours after injury, is almost certain to be wrong.

At this second visit, it can safely be assumed that the sources of bleeding have sealed off and heat therapy, followed by gentle centripetal massage, can be started. Electronic and other complicated sources of heat have little advantage over hot water. Diathermy, in fact, is contraindicated in joint injuries since it tends to produce effusion. The psychological effect of a whirlpool bath is much greater than the massage of moving water and bubbles.

Weight-bearing is permitted as soon as natural walking is possible. When pain on manipulation and tenderness approach the vanishing point, the ankle is taped and the player is put through his paces on the playing field under the eye of his doctor, coach, and trainer. He returns to full activity only if his performance is flawless. The ankle is protected by adhesive tape, with turns around the heel to minimize lateral mobility for at least the next year for every practice session and game. The old adage "once a sprain, always a sprain" has sound basis in the fact that ligament heals with scar, which is only slowly replaced by orderly elastic collagenous tissue, and the disorganized fibroblast pattern of scar is always weaker than the tissue it replaces.

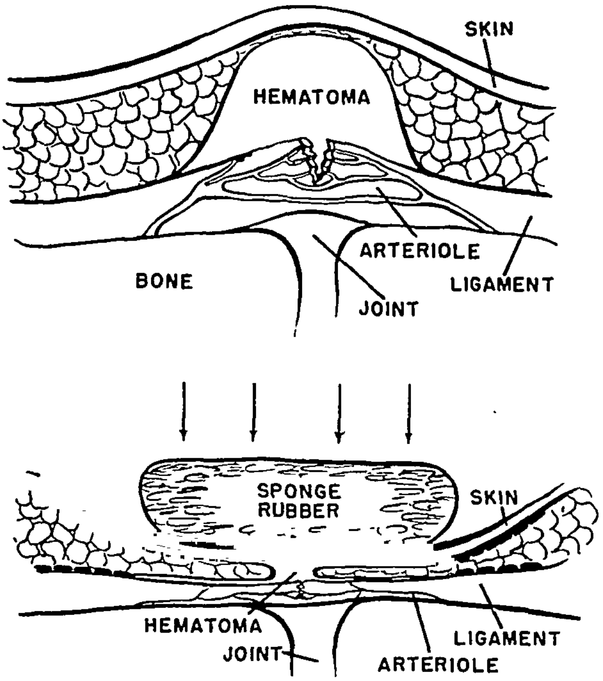

Fig. 7.—Effect of compression on hematoma accompanying a sprain. Blood is disseminated through tissue planes, increasing its surface and speeding absorption.

There is no justification whatever for the use of procaine in any athletic injury. Pain may temporarily be abolished, but performance is usually poor and further damage to the injured structure is almost inevitable. Hyaluronidase and hydrocortisone may have a place when hemorrhage is unusual in degree or sensitivity to pain high. But it must be remembered that arthrocentesis is no different from arthrotomy, from a bacteriological point of view, and a locker room is hardly as safe as an operating theater. Further, no analgesic substance should ever be injected unless it is absolutely clear that pain is much greater than the basic ligament injury usually produces.

Plaster splints are used only for severe or multiple sprains, and are removed as soon as possible. Atrophy of thigh and calf musculature can occur at a remarkable rate and can be corrected only by careful, daily, supervised, progressive resistance exercise.

Summary

A program of management of ankle injuries sustained in sport has been developed over seven decades of experience at the Harvard Department of Athletics and includes methods of prevention, prompt diagnosis, and implementation of treatment for major and minor injuries.

EFFECTS OF IONIZING RADIATIONS ON BENIGN LESIONS.—Irradiation for benign conditions may produce tissue changes more disabling than the original condition for which the x-rays were administered. A latent period of several decades between exposure to irradiation and tissue breakdown is common. Thus, those who administer the irradiation may be unaware of the late consequences. Cancer developed in 22 per cent of the 165 cases reviewed in this study and can be predicted in others. Contrary to previous teaching, carcinoma in irradiated skin of the face is usually of the basal-cell type. The morbidity of this entity is high, but death from radiation necrosis is rare. Surgical therapy should be prompt and thorough. Prophylactic excision may preclude the ultimate development of carcinoma. Evidence gained from this study and those of others suggests that those not fully qualified in the therapeutic use of x-rays be excluded from the application of this potentially dangerous tool.—Bradford Cannon, M.D., J. G. Randolph, M.D., and J. E. Murray, M.D., Malignant Irradiation for Benign Conditions, *The New England Journal of Medicine,* Jan. 29, 1959.

low no definite calendar, and the degree and extent to which they occur vary greatly even in individuals of advanced age. Not all degenerative changes are of clinical importance, and, as McRae has pointed out, disks may bulge, herniate, or rupture without any symptoms whatsoever.

This paper is written as a contribution toward a better understanding of degenerative arthritis of the lumbosacral joint. The significance of clinical and roentgen findings to be described will be considered controversial by some. Nonetheless, I feel that a reasonable approach to the treatment of low back pain of intrinsic cause must come from a better understanding of degenerative arthritic lesions which occur in the lower lumbar region of the spine and particularly in the lumbosacral joint.

This joint, the end-space of the movable spine, is a compound articulation which consists of an intervertebral disk and two facet joints. The disk is an amphiarthrosis, a modified joint with a ball-bearing-like action. The facet joints are diarthroses or true movable articulations. The first sacral nerve root bears an intimate relation both to the disk and to the facet joints. The lumbosacral joint, subjected to the greatest amount of superincumbent body weight, is more prone to degenerative disease than any other joint in the lumbar spine. In 222 patients examined over the three-year period, 1955 to 1958, degenerative arthritis occurre ion of L-3 in 5 patients, the region of l bo-sacral region in 160, and the reg -5 in 35.

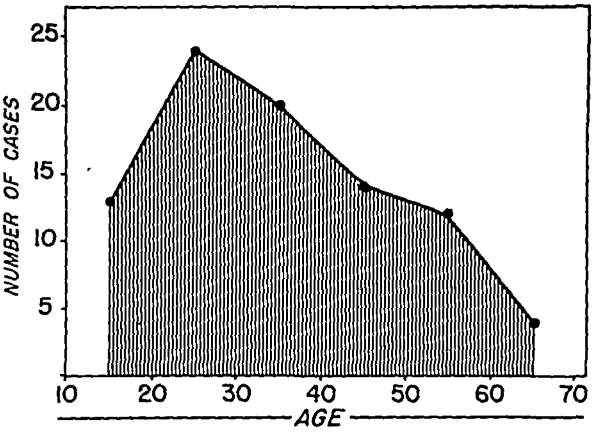

Fig. 1.—Graph showing ages of patients at onset of symptoms of lumbosacral arthritis.

The importance of the lumbosac of degenerative arthritis has bee orthopedists generally, but this co slow to extend beyond the confines Goldthwait,[9] in 1911, described a par followed forcible manipulation of the in a 39-year-old man. The patient's sig toms, viewed in light of present-day would have indicated a diagnosis of p niation of the lumbosacral disk. The catastrophic result which occurred after forcible manipulation under ether anesthesia caused Dr. Goldthwait to make extensive anatomic studies of the lower lumbar region of the spine. His article, a landmark in the recorded history of orthopedic surgery, is the first to place emphasis upon the lumbosacral joint as the site of disease which can cause pain in the lower back and legs. Prior to his article, and even subsequent to it, the sacroiliac joint, rather than the lumbosacral, has been considered the offending articulation. The concept of sacroiliac displacement as a cause of low back pain is dying a lingering death, but it is far from dead.

Method of Study

One hundred twenty-five patients, of whom 83 are female and 42 are male, were chosen for this study. The patients in the study, and whenever possible their families, were questioned carefully on repeated occasions in an effort to obtain histories of a high degree of accuracy. Special attention was given to the history, for prior to the first examination many had been treated for long periods of time by doctors of varying disciplines. The nature of the treatment that had been rendered and the patient's response to it efully recorded. The type, frequency, an n of acute episodes of pain were chart l differentiation between acute and ch toms has been [illegible]

Eleven patients were treated because of injuries sustained in industrial accidents. It is of interest that roentgenograms taken at the time of injury showed preexisting lumbosacral arthritis in 10 of these patients, and, therefore, their accidents were considered aggravations of an already existing degenerative disease. Included in the study are members of 10 families in whom there was definite evidence of a hereditary tendency toward degeneration of the lumbosacral joint (fig. 2).

The duration of symptoms prior to the initial examination varied from 1 to 40 years. Every conceivable type of treatment had been rendered, including heat of all kinds, medicaments too numerous to record, supports of many types, exercises, traction, and manipulation. It soon became apparent from scrutiny of histories that the type of treatment rendered in the early stages of disk degeneration seems to make little difference. Acute symptoms subsided in a few days regardless of what was done. With respect to manipulative therapy, questioning of the patients indicated that in the first years of their disease such treatment often gave relief. However, as the degenerative process of the lumbosacral joint progressed, manipulations either gave no relief or aggravated symptoms.

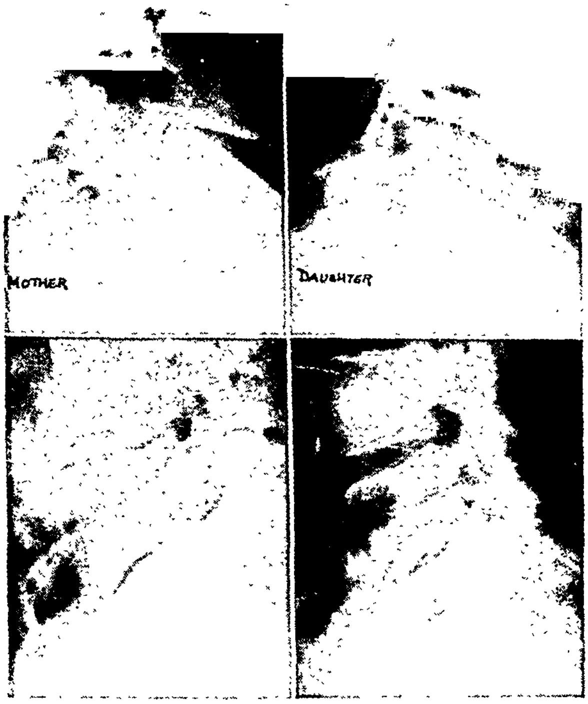

Fig. 2.—*Above*, lateral roentgenograms of lumbosacral joint of woman (*left*) aged 52 and her daughter (*right*) aged 38. *Below*, lateral roentgenograms of lumbosacral joints of two sisters, (*left*) aged 62 and (*right*) aged 56. Note obliteration of joint space.

Patients who ventured a diagnosis at the time of the first examination stated almost invariably that their sacroiliac joints slipped out of place. The frequency of this diagnosis seems to give further evidence of the extent to which this misconception is fixed in the minds of both laymen and physicians alike.

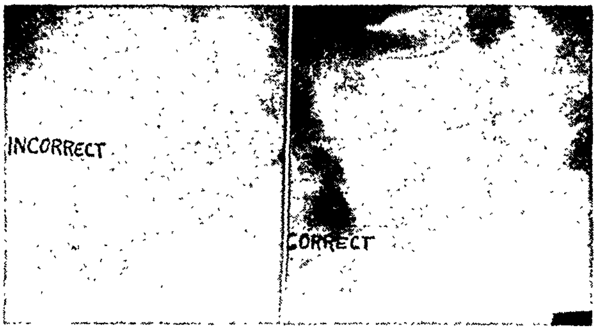

Fig. 3.—Lateral roentgenograms of lumbosacral joint in patient, emphasizing ease with which diagnosis can be missed in poorly centered film and ease with which it can be made in a well-centered film.

Regardless of whether the onset of the disease was acute or chronic, progress of lumbosacral arthritis is characterized by recurrent attacks of low back pain with or without sciatic radiation. These attacks occur at intervals of several weeks to several months. They tend to increase in severity.

Usually the actual attack occurs from a simple body motion such as bending forward to make a bed or to wash one's hands. However, the episode of intense pain is frequently preceded by a period of physical exertion, fatigue, emotional upset, or respiratory infection. The stress of the year-end holidays seems to predispose many patients to an acute attack.

With collapse of the disk space, derangement of the facet joints increases, and chronic symptoms appear. By far the most common of these is stiffness in the lower back on arising from bed in the morning. Some patients are awakened in the early hours of the morning by pain in the lower lumbar region. Others are comfortable until they attempt to arise from bed. The act of assuming the upright posture is painful and difficult. Stiffness and pain may persist for from ½ to 2 hours, but these symptoms gradually lessen with increasing physical activity. Other chronic symptoms include backache with prolonged sitting, pain in the lower back on arising from a sitting posture, backache with prolonged standing, and backache with physical exercise. A housewife with advanced lumbosacral arthritis has great difficulty making a bed, standing to wash dishes, or bending over to use a vacuum cleaner. A businessman finds it painful to sit through a lengthy conference or through a lengthier bridge game. These chronic symptoms are not to be underestimated. They can place se-low no definite calendar, and the degree and extent to which they occur vary greatly even in individuals of advanced age. Not all degenerative changes are of clinical importance, and, as McRae has pointed out, disks may bulge, herniate, or rupture without any symptoms whatsoever.

This paper is written as a contribution toward a better understanding of degenerative arthritis of the lumbosacral joint. The significance of clinical and roentgen findings to be described will be considered controversial by some. Nonetheless, I feel that a reasonable approach to the treatment of low back pain of intrinsic cause must come from a better understanding of degenerative arthritic lesions which occur in the lower lumbar region of the spine and particularly in the lumbosacral joint.

This joint, the end-space of the movable spine, is a compound articulation which consists of an intervertebral disk and two facet joints. The disk is an amphiarthrosis, a modified joint with a ball-bearing-like action. The facet joints are diarthroses or true movable articulations. The first sacral nerve root bears an intimate relation both to the disk and to the facet joints. The lumbosacral joint, subjected to the greatest amount of superincumbent body weight, is more prone to degenerative disease than any other joint in the lumbar spine. In 222 patients examined over the three-year period, 1955 to 1958, degenerative arthritis occurred in the region of L-3 in 5 patients, the region of L-4 in 22, the lumbosacral region in 160, and the region of L-4 and L-5 in 35.

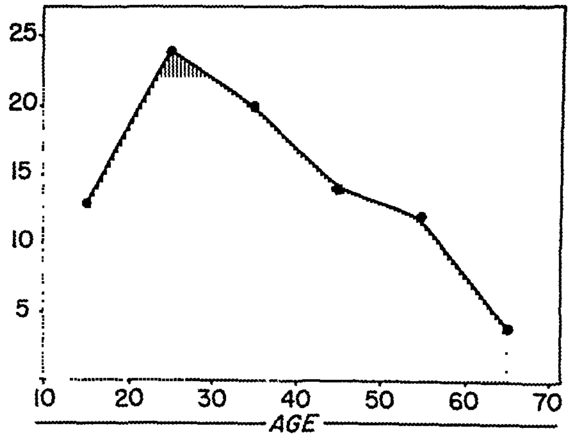

Fig. 1.—Graph showing ages of patients at onset of symptoms of lumbosacral arthritis.

The importance of the lumbosacral joint as a site of degenerative arthritis has been recognized by orthopedists generally, but this concept has been slow to extend beyond the confines of the specialty. Goldthwait,[9] in 1911, described a paraplegia which followed forcible manipulation of the lumbar spine in a 39-year-old man. The patient's signs and symptoms, viewed in light of present-day knowledge, would have indicated a diagnosis of posterior herniation of the lumbosacral disk. The catastrophic result which occurred after forcible manipulation under ether anesthesia caused Dr. Goldthwait to make extensive anatomic studies of the lower lumbar region of the spine. His article, a landmark in the recorded history of orthopedic surgery, is the first to place emphasis upon the lumbosacral joint as the site of disease which can cause pain in the lower back and legs. Prior to his article, and even subsequent to it, the sacroiliac joint, rather than the lumbosacral, has been considered the offending articulation. The concept of sacroiliac displacement as a cause of low back pain is dying a lingering death, but it is far from dead.

Method of Study

One hundred twenty-five patients, of whom 83 are female and 42 are male, were chosen for this study. The patients in the study, and whenever possible their families, were questioned carefully on repeated occasions in an effort to obtain histories of a high degree of accuracy. Special attention was given to the history, for prior to the first examination many had been treated for long periods of time by doctors of varying disciplines. The nature of the treatment that had been rendered and the patient's response to it was carefully recorded. The type, frequency, and duration of acute episodes of pain were charted. Careful differentiation between acute and chronic symptoms has been possible. The progress of the disease has been recorded by careful serial roentgenographic study.

My associates and I have had the unique opportunity of treating siblings and successive generations of the same family with lumbosacral arthritis. The hereditary nature of the disease has become increasingly apparent. Treatment, whether conservative or surgical, has been carried out along certain definite patterns, so that an opinion of some value can be given as to the response of these patients to the care rendered. The majority have been treated conservatively. Some have been followed for as long as 20 years. Clinical data from various age groups have been gathered and sifted. By taking a perspective in length it has been possible to record, in part, the natural history of this disease.

Symptoms in Lumbosacral Arthritis

Of the 125 patients, 87 were aware of the age at which symptoms developed. Most developed symptoms while under the age of 40 (fig. 1). Eighty-four patients were aware of the exact nature of their first symptoms. Twenty-four noted dull ache in the lower back which came on without any known cause. Forty-six had an acute attack of low back pain which resulted from a simple body motion. Fourteen gave histories of real trauma to the lower back which resulted usually from lifting weights in excess of 100 lb.

Eleven patients were treated because of injuries sustained in industrial accidents. It is of interest that roentgenograms taken at the time of injury showed preexisting lumbosacral arthritis in 10 of these patients, and, therefore, their accidents were considered aggravations of an already existing degenerative disease. Included in the study are members of 10 families in whom there was definite evidence of a hereditary tendency toward degeneration of the lumbosacral joint (fig. 2).

The duration of symptoms prior to the initial examination varied from 1 to 40 years. Every conceivable type of treatment had been rendered, including heat of all kinds, medicaments too numerous to record, supports of many types, exercises, traction, and manipulation. It soon became apparent from scrutiny of histories that the type of treatment rendered in the early stages of disk degeneration seems to make little difference. Acute symptoms subsided in a few days regardless of what was done. With respect to manipulative therapy, questioning of the patients indicated that in the first years of their disease such treatment often gave relief. However, as the degenerative process of the lumbosacral joint progressed, manipulations either gave no relief or aggravated symptoms.

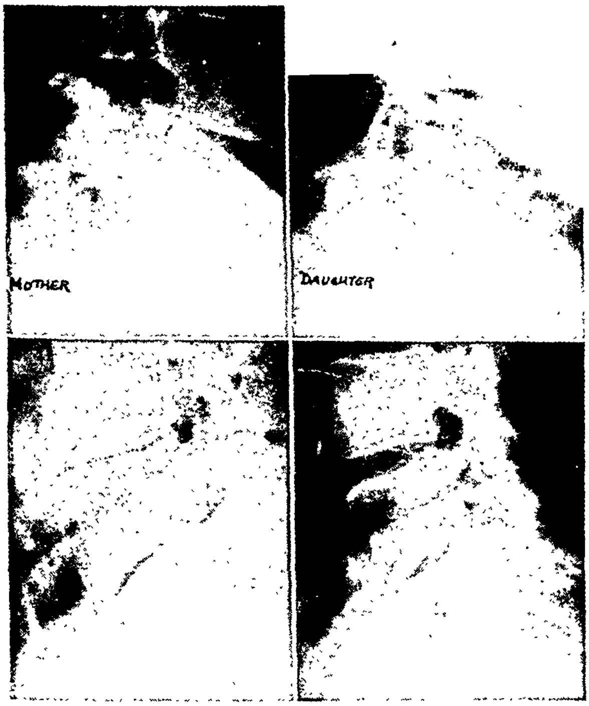

Fig. 2.—*Above*, lateral roentgenograms of lumbosacral joint of woman (*left*) aged 52 and her daughter (*right*) aged 38. *Below*, lateral roentgenograms of lumbosacral joints of two sisters, (*left*) aged 62 and (*right*) aged 56. Note obliteration of joint space.

Patients who ventured a diagnosis at the time of the first examination stated almost invariably that their sacroiliac joints slipped out of place. The frequency of this diagnosis seems to give further evidence of the extent to which this misconception is fixed in the minds of both laymen and physicians alike.

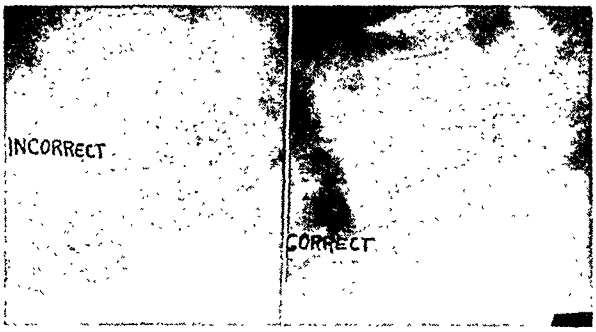

Fig. 3.—Lateral roentgenograms of lumbosacral joint in patient, emphasizing ease with which diagnosis can be missed in poorly centered film and ease with which it can be made in a well-centered film.

Regardless of whether the onset of the disease was acute or chronic, progress of lumbosacral arthritis is characterized by recurrent attacks of low back pain with or without sciatic radiation. These attacks occur at intervals of several weeks to several months. They tend to increase in severity.

Usually the actual attack occurs from a simple body motion such as bending forward to make a bed or to wash one's hands. However, the episode of intense pain is frequently preceded by a period of physical exertion, fatigue, emotional upset, or respiratory infection. The stress of the year-end holidays seems to predispose many patients to an acute attack.

With collapse of the disk space, derangement of the facet joints increases, and chronic symptoms appear. By far the most common of these is stiffness in the lower back on arising from bed in the morning. Some patients are awakened in the early hours of the morning by pain in the lower lumbar region. Others are comfortable until they attempt to arise from bed. The act of assuming the upright posture is painful and difficult. Stiffness and pain may persist for from ½ to 2 hours, but these symptoms gradually lessen with increasing physical activity. Other chronic symptoms include backache with prolonged sitting, pain in the lower back on arising from a sitting posture, backache with prolonged standing, and backache with physical exercise. A housewife with advanced lumbosacral arthritis has great difficulty making a bed, standing to wash dishes, or bending over to use a vacuum cleaner. A businessman finds it painful to sit through a lengthy conference or through a lengthier bridge game. These chronic symptoms are not to be underestimated. They can place severe limitations upon the life of the patient. Constant backache is an irksome burden for anyone to bear.

The location and radiation of pain from the lumbosacral joint is not constant. Inman and Saunders,[9A] in 1944, pointed out that localization of pain from irritation of deeply placed skeletal structures is poor. They further demonstrated the variability in the response of deep structures to painful stimulation. Lumbosacral pain may be felt in the midline of the lower back, over the coccyx, over one or both sacroiliac joints, in the buttocks, in the lower abdominal quadrants, or in the groin. If the first sacral nerve root is irritated, true sciatic pain is felt. Unusual radiation of pain from the lumbosacral joint has led to the unnecessary removal of the coccyx and pelvic organs, especially in the female.

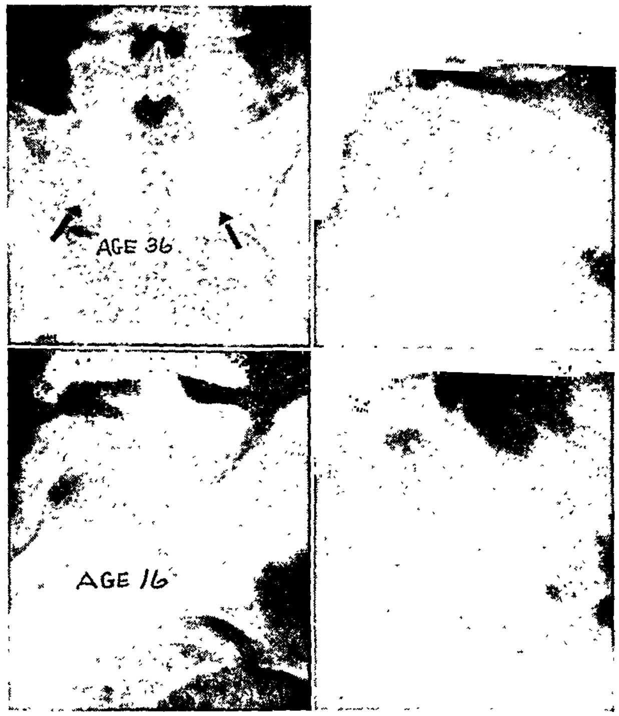

Fig. 4.—*Above,* anteroposterior and lateral roentgenograms of lumbosacral joint in 36-year-old woman. Note symmetrical collapse of disk space, lipping of anterior vertebral margins, and extreme sclerosis of superior articular plate of sacrum. *Below,* roentgenograms of lumbosacral joint of 16-year-old girl who had had symptoms for four years. Note narrowing of disk space in lateral view and loss of joint space as well as subluxation of facet joint in oblique view.

A patient examined in the acute phase of the illness demonstrates marked restriction of motion in the lumbar spine, muscle spasm, tenderness to palpation over the lumbosacral joint, and, depending upon whether the sciatic nerve is irritated or not, hamstring spasm and alteration in the achilles reflex. The signs of nerve root irritation are variable. They may be present with one attack and absent with the next. They bear no direct relationship to the degree of disk disintegration. Patients with total collapse of the lumbosacral disk space have never had leg pain, whereas others with a lesser degree of collapse have had intermittent severe leg pain.

A patient examined in the chronic phase of the disease may show surprisingly little on physical examination. Slight restriction of motion in the lumbar region of the spine and tenderness upon firm palpation of the spinous process of the fifth lumbar vertebra may be the only significant positive findings. A depressed or absent achilles reflex may be a single clue to chronic irritation of the first sacral nerve root.

The diagnosis of lumbosacral arthritis can be strongly suspected from the history and physical findings, but accurate diagnosis depends upon adequate roentgenograms. In view of the slowly progressive nature of the disease, serial x-rays are sometimes needed before the diagnosis is confirmed. Films should include standard anteroposterior and lateral views of the lumbar region of the spine with oblique views and a coned lateral view of the lumbosacral joint. Standing lateral x-rays of the lumbosacral articulation taken with the spine in flexion and extension are also helpful. The importance of accurate centering in the lateral view is especially stressed (fig. 3).

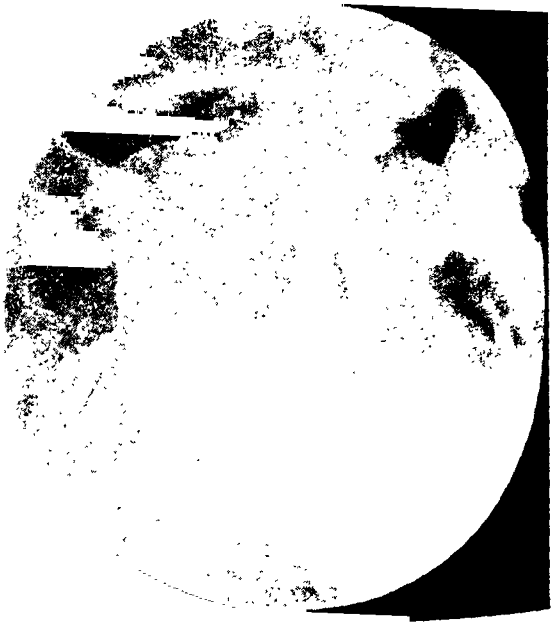

Fig. 5.—Oblique roentgenogram of facet joint at lumbosacral level in 50-year-old woman. Facets are subluxated. Superior sacral facet has impinged on pedicle of fifth lumbar vertebra to such degree that notch has formed in pedicle.

The roentgenographic characteristics of lumbosacral arthritis are demonstrated in figures 4 and 5. The progressive nature of the end-space lesion is well illustrated in figure 6.

If posterior herniation of the disk is suggested by positive neurological findings, a myelogram should be taken, provided the patient is not sensitive to iodine. In my experience, the taking of a myelogram has proved to be a procedure of low risk and high yield. No untoward results have been encountered other than headache. The electromyogram, while occasionally useful, has not proved as valuable a diagnostic aid as the myelogram.

Methods of Treatment

Eighty-three patients have been treated conservatively, and forty-two have been subjected to lumbosacral fusion. Adherence to the principle of rest has guided treatment of the acute attack. Adhesive strapping, suitable anodynes, and confinement to bed have resulted in prompt relief of acute symptoms in three to seven days. Physical therapeutic measures, including luminous heat, deep muscular massage, gentle stretching, and postural exercises, have been beneficial. A firm mattress and a bed board are indispensable. The use of a simple wedge-shaped car seat cushion can make driving for these patients a pleasure instead of an ordeal. Manipulation of any sort has been assiduously avoided.

The therapeutic aid used most frequently, both for the control of chronic symptoms and for postoperative support, has been the Goldthwait back brace (fig. 7). Made of light spring steel and covered in washed kid leather, it is comfortable to wear and is accepted without complaint by the majority of patients. The brace not only relieves chronic symptoms but it enables the patient to engage in light physical exercise without fear of an incapacitating attack of pain. Some patients in this study have worn a Goldthwait brace intermittently for as long as 20 years with remarkable relief of pain. Both backache and sciatic pain have been relieved through its use. In addition to the use of the brace, patients have been instructed in simple postural exercises. When indicated, weight reduction has been urged.

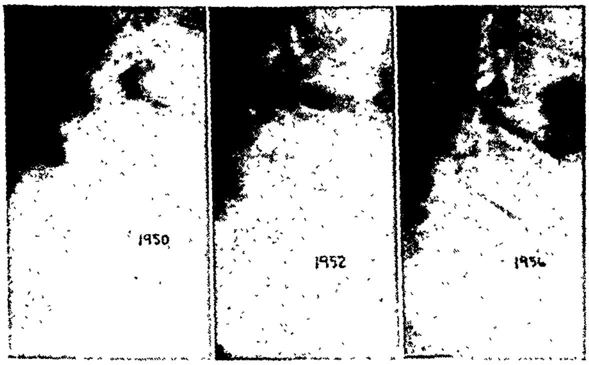

Fig. 6.—Lateral roentgenograms of lumbosacral joint of 43-year-old woman showing progression of disease over six-year period.

Of the 42 patients subjected to lumbosacral fusion, 13 had backache alone and 29 had both backache and leg pain. Of those with leg pain, 14 had posterior herniations of the nucleus pulposus. Ten of these were recent and four were older. In the remaining 15 patients, leg pain was found to be due to foraminal encroachment upon the first sacral nerve from collapse of the disk space. Forty-one patients developed solid bony fusions and one had failure of fusion. The failure occurred in the oldest patient operated on, a woman aged 57 years.

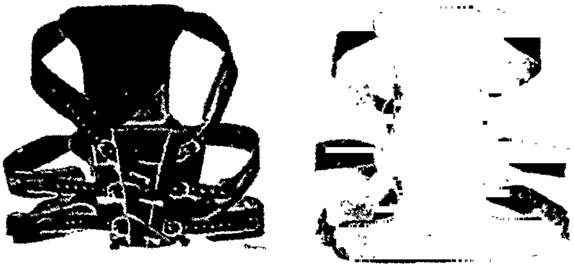

Fig. 7.—Goldthwait back brace.

The fusions have been done according to a modified Hibbs technique. Partial denervation of the joint is accomplished by total excision of the ligamenta flava. In addition, the cartilage, synovia, and capsular membranes of the facet joints have been removed. The defect in the facet is filled with bone chips from the adjacent lamina. The laminal arches of the fifth lumbar and first sacral vertebrae have been subjected to erasion, and the fusions have been completed with cancellous bone taken from the posterior superior spine of the ilium. Partial interruption of the nerve supply to the lumbosacral joint,[10] as well as decompression of the first sacral nerve roots, accounts for the improvement which patients note even in the immediate postoperative period.

No support other than adhesive tape and wound dressings has been used during the first 10 days after surgery. Between the 10th and 14th day a Goldthwait brace is fitted, which the patient wears in bed for increasing periods of time. On the 21st day ambulation is begun. The brace is worn night and day for four months and for an additional two months in the daytime only. The integrity of all fusions was tested by bending films taken nine months to one year after operation.

Results

The results in this small series of fusions are as follows: In 18 patients the results are considered excellent. The patients have no symptoms whatsoever and on physical examination demonstrate no limitation of motion in the lumbar region of the spine. Each admits to complete relief of preoperative complaints. Seventeen have had good results. Their symptoms have been relieved except for occasional mild back or leg ache, usually after exertion. However, they all demonstrate 25% loss of motion in the lumbar region of the spine, particularly in extension and lateral flexion. Two patients have had fair results, for, though fusion occurred, they complain of intermittent back and leg ache. However, both admit to considerable benefit from operation. Two are considered to have poor results. Their lumbosacral joints have fused, but they have many subjective complaints which are not explained by objective findings. One patient has a failure of fusion but is asymptomatic. Two patients have developed degenerative disk disease above the site of fusion. A woman, now aged 52, has a symptomatic lesion at the third lumbar interspace 20 years after surgery. Another woman, now aged 38, has roentgen evidence of an early degenerative lesion at the fourth space which became symptomatic after a severe respiratory infection complicated by paroxysmal coughing. Both of these complications, if they may be so termed, have been treated conservatively with relief of pain to date.

Fusion of the lumbosacral joint has proved to be an excellent procedure, for it has relieved the acute and chronic symptoms of lumbosacral arthritis in 83% of these patients. The operation provides no assurance against further episodes of back ache, for 131 movable joints remain above the area of fusion.

These patients have not all been followed for 20 years. No prophecy is made as to their future complaints. However, taken as a group, their response to operation has been most gratifying, and these operative results are far better than those in patients subjected to so-called disk surgery alone.

Summary and Conclusions

Lumbosacral arthritis is a chronic progressive disease which may be hereditary. Symptoms can appear as early as the second decade of life, but most patients develop backache from this cause in the third or fourth decades. Onset of symptoms may be acute or chronic. While severe attacks occur generally from a simple body motion, they are preceded by fatigue, emotional strain, infection, and occasionally trauma. Although backache is a constant symptom, sciatic pain may or may not be present. There is no definite correlation between collapse of the disk space and irritation of the first sacral nerve root. With progressive loss of disk space and concurrent degeneration of the facet joints, chronic symptoms appear. These may place severe limitations upon the life of the patient and can at times become incapacitating. While conservative treatment of lumbosacral arthritis is often both practical and advisable, spinal fusion in the carefully selected patient relieves the acute and chronic symptoms of the disease.

The author of an essay on backache is likely to find himself making a series of positive statements. There is harm in being always positive, for one may not be always right. The conclusions reached in this paper have not been arrived at hastily. They have been formulated after careful study. The diagnostic criteria and roentgenologic interpretations are founded upon a firm belief that degenerative disease in the lumbar vertebral joints, and especially in the lumbosacral joint, is the major cause of chronic recurrent severe low back pain with or without sciatic radiation. The treatment which has been described, while not the only approach, is reasonable, conservative, and effective.

Morbidity from low back pain is of concern to the general practitioner as well as to the specialist. There is need throughout the profession of medicine for dissemination of knowledge concerning the pathological anatomy of the spine so that the diagnosis and treatment of one of man's most common afflictions will rest upon a firmer scientific basis.

LATE RESULTS IN OSTEOCHONDROSIS OF CAPITAL EPIPHYSIS OF FEMUR (LEGG-CALVÉ-PERTHES DISEASE)

Warren G. Stamp, M.D., Gregorio Canales, M.D.
and
Richard T. Odell, M.D., St. Louis

In treating osteochondrosis of the capital epiphysis of the femur, it has been difficult to evaluate results and consequently difficult to compare the effectiveness of various methods. There is a need for more reliable measures of hip function and better criteria of results. Of 132 patients in the present series, 34 were treated with bed rest and traction, 31 with crutch and sling, and 25 with crutch and lift; 42 received inadequate treatment or none at all. The percentage of results classified as satisfactory or fair was highest (93%) in the group with bed rest and traction. This group included 10 of the 14 patients with both hips affected. The group inadequately treated had satisfactory or fair results in only 30% of cases. Treatment by means other than bed rest and traction is feasible only if the disease is unilateral and the patient cooperates.

The management of osteochondrosis of the capital epiphysis of the femur (Legg-Calvé-Perthes disease) has been controversial since the original description in 1910.[1] In 1934 Danforth[2] demonstrated the rationale of non-weight-bearing treatment to prevent deformity in the disease. In 1936 Eyre-Brook[3] compared his results of bed rest and traction versus other non-weight-bearing methods of treatment. In 1940 Gill[4] confirmed Eyre-Brook's report, and both claimed essentially normal hips as a result in every case, if therapy with bed rest and traction was begun prior to deformity. In 1951 Pedersen and McCarroll[5] reported the experience at the St. Louis Unit of Shriners Hospital for Crippled Children with bed rest and traction versus ambulatory non-weight-bearing means, and they also concluded that bed rest gave vastly improved results.

Methods

For approximately five years after Pedersen and McCarroll's report, we continued with the bed rest and traction regimen. The crutch and sling replaced the previously used crutch and shoe lift in patients whom we felt would cooperate. Since 1956, only an occasional patient has been admitted to the hospital for a full course of bed rest and traction. At present, traction is used only for a short period to allow the muscle spasm to subside, and then the crutch and sling is recommended. The patients with bilateral cases are still treated by bed rest whether at home or in the hospital. The patients in this series have all been seen at the St. Louis Unit of the Shriners Hospital for Crippled Children. When it was not possible for the patients under study to return to St. Louis for the follow-up examination, we utilized a Shriners hospital in the immediate area or an orthopedic surgeon who would complete the examination. The type of therapy recommended has not been contingent on the financial situation of the family as long as they are eligible for our service. Hospitalization is free, and we have the public school system in the hospital; thus we are not influenced for economic reasons as to which would be the ideal way of managing the patient.

We were interested in ascertaining the outcome of the original patients reported by Pedersen and McCarroll and also in determining whether it is desirable to discontinue the bed rest treatment. Mindell and Sherman[6] could not find a statistical difference between the ambulatory and the nonambulatory methods, provided the therapy was started early. Heyman and Herndon[7] used a modified program consisting of bed rest until regeneration of the femoral head was noted, 6.3 months on the average, and then followed with a non-weight-bearing brace. They reduced the hospital time without endangering the outcome of the patient.

We have seen 224 patients with osteochondrosis of the capital epiphysis of the femur between 1926 and 1957. The follow-up period has ranged from 5 to 32 years and includes 138 patients. An additional 33 patients have not completed the course of their disease and thus cannot be included in this study.

Evaluation of our results was difficult, and a sincere attempt was made to utilize the comprehensive quotient advocated by Heyman and Herndon. We found that no two observers could measure the adult deformed hip and obtain comparable figures. This difficulty arises when the epiphysis is closed, when the head is slightly or moderately deformed,

---

From the St. Louis Unit, Shriners Hospital for Crippled Children, and the Department of Surgery, Washington University School of Medicine.

Read before the Section on Orthopedic Surgery at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

and when x-rays are not taken with the hips in similar rotations. We used the epiphysial quotient (fig. 1) as a numerical index in evaluating our cases, and, to reduce the error of variation in measurement, one man did all the calculation. The measurement is taken as the height of the epiphysis divided by the greatest width of the head, as described by Eyre-Brook. Herndon used the width of the epiphysis, but this is not possible to measure in the patients with older cases when the line is closed and the head is deformed. The measurement for the normal hip is then divided into that for the diseased hip to determine the apparent percentage of normal. We used 40.7 as the epiphysial index in patients under 15 years old and 37.8 for patients over 15 in determining the epiphysial quotient in the bilateral cases.

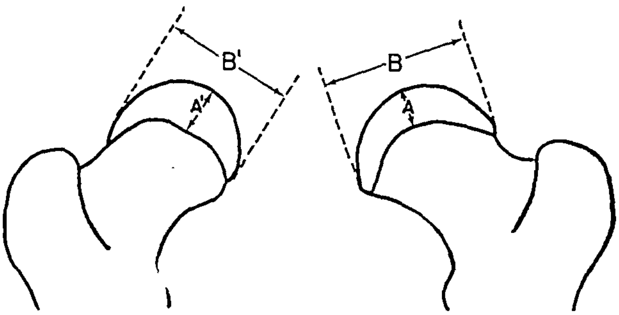

Fig. 1.—Epiphysial quotient described by Herndon but measured by Eyre-Brook's method. *Left,* normal hip. A′=21 mm.; B′=54 mm.; and index 100 A′/B′=39. *Right,* hip affected by osteochondrosis of capital epiphysis of femur (Legg-Calvé-Perthes disease). A=17 mm.; B=61 mm.; and index 100 A/B=28. Epiphysial quotient=28/29=72%.

Mindell and Sherman utilized a simple and broad classification embracing the clinical and radiographic examinations in a follow-up study of the disease. We have attempted to follow their criteria, and even with this relatively flexible classification some difficulty was encountered. A satisfactory hip (fig. 2) is one that is symptom-free but may have a few degrees of limitation of motion. The x-ray shows the hips to be without deformity. A fair result (fig. 3) has occurred when there are minor complaints, and 1 to 2 cm. of shortening will be noted. X-rays show a moderately flattened and widened femoral head, with or without acetabular changes. Patients with poor results (fig. 4) will have more pain, limp, and have some disability. There will be significant limitation of rotation and abduction. X-rays demonstrated gross deformity of the femoral head and neck and occasionally of the acetabulum.

Results in 132 Patients with Osteochondrosis of the Capital Epiphysis of the Femur (Legg-Calvé-Perthes Disease)

Method of Treatment	Patients, No.	Hips, No.	Results, No. Satisfactory	Fair	Poor	% of Satisfactory or Fair Results

Crutch and sling	31	31	14	7	10	67
Crutch and lift	25	27	5	11	11	59
Inadequate or none	42	44	6	8	30	30

Results

The 132 patients in our series, with 146 affected hips, have been divided into four groups, according to method of treatment. The results of treatment are shown in the table. The first group was treated with traction, the second with crutch and sling, and the third with crutch and lift. The fourth group is made up of those patients who received no treatment or inadequate treatment or who were seen so late that treatment could not be expected to reverse the severe deformities already established. Those who were seen early but did not cooperate were retained in one of the three specific treatment groups, as lack of cooperation represents one of the hazards of treatment. Even after reviewing this series of cases, we are still uncertain as to the best method of treatment for patients who are seen late in the course of their disease and with seemingly severe established deformity.

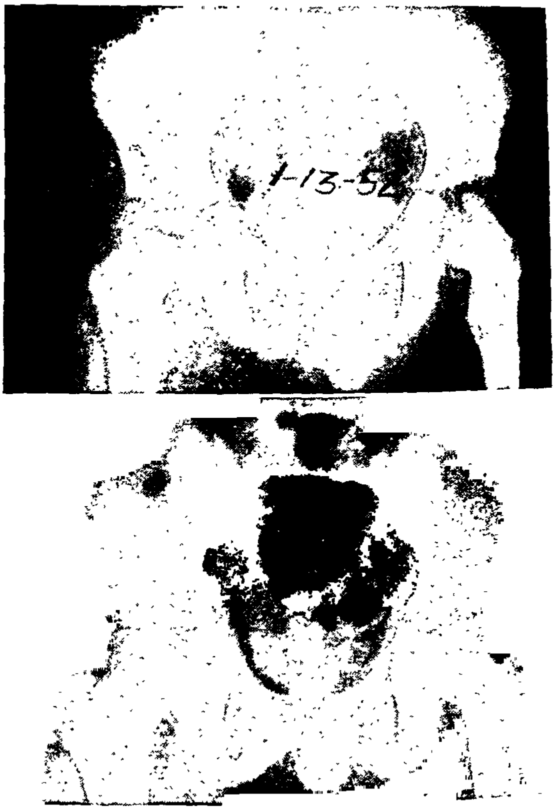

Fig. 2.—*Above,* roentgenogram made when patient was first seen at age 4. *Below,* satisfactory result, with no pain or limp, about six years later.

We attempted to correlate these results with the epiphysial quotient and found that in the groups with satisfactory results the hip was 70% or more of normal, the hips in which results were fair varied between 55% and 70%, and those in which results were poor were under 55% of normal. It was also noted that for 28% of the satisfactory hips the epiphysial quotient was lower than 70%, such as in the example shown in figure 5, which we considered satisfactory but in which the epiphysial quotient was 63. We also found that 25% of the fair results did not fall within the prescribed range and 10% of the poor exceeded 55% of normal.

All of the above patients were followed for at least 5 years and some for as long as 32 years (fig. 6). The average length of follow-up by groups is bed rest and traction, 8 years; crutch and sling, 6.6 years; crutch and lift, 12.2 years; and inadequate treatment, 19.8 years. The average follow-up period for the entire group was 11.8 years. Ninety-five per cent of the patients in this series have been seen during the six months prior to the time of writing for clinical and roentgenographic examination.

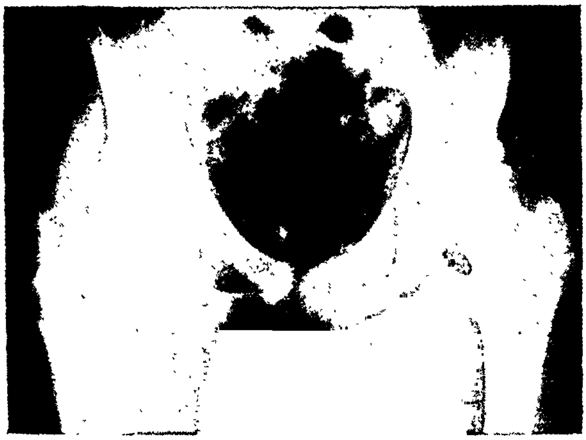

Fig. 3.—Patient treated with crutch and sling for 29 months. Fair results seven years later include no pain, no limp, negative results from Trendelenburg test, 1-in. thigh atrophy, and 0.5 in. shortening.

It is interesting that in the three so-called adequately treated groups, the length of treatment was virtually the same. In the bed rest and traction group, the average length of time this therapy was used was 17.7 months. Unrestricted weight-bearing was not permitted, however, for an additional 11.2 months, for a total treatment time of 28.9 months. Those with the crutch and sling were treated for an average of 27.4 months and those with a crutch and lift for 26.7 months. The additional therapy in the bed rest and traction group was with the use of a crutch and sling. Ten patients in the traction group were allowed unrestricted weight-bearing after traction was discontinued.

We have attempted to analyze the three poor results in two patients in the traction group. One of these two patients had bilateral involvement and was kept in bed for 56 months (fig. 7). Although therapy was begun early in this case, we still are unable to understand why it failed. The other failure was due to our error in permitting too early weight-bearing and demonstrates that even if the hip has started to regenerate flattening can occur.

Six of the 11 patients with poor results in the crutch and lift group were uncooperative, as were 6 of the 10 in the crutch and sling group. Thus, if we were to remove the uncooperative patients from these latter two groups, the number of those classified as having poor results would be virtually the same in the treated patients.

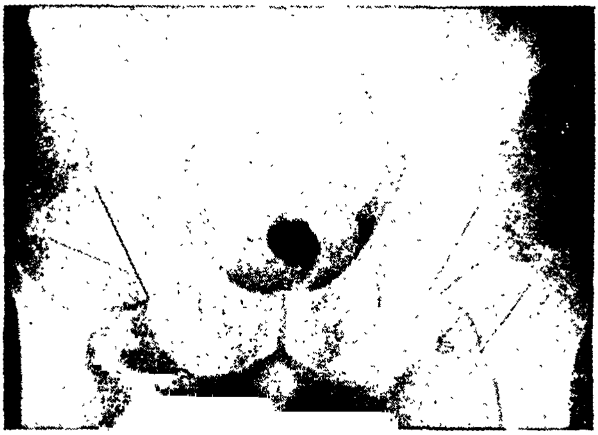

Fig. 4.—Poor result, after 31 years, in patient, first seen at age 9, with symptoms for two years. He was not adequately followed but supposedly wore an ischiatic weight-bearing brace for eight years.

Perhaps the main advantage of the traction treatment is that we force the patient to cooperate, and the calculated risk one takes in treating this disease with the ambulatory non-weight-bearing method is removed. Thirty per cent of the inadequately treated group had a satisfactory or fair result. These were not followed as closely, but 40%

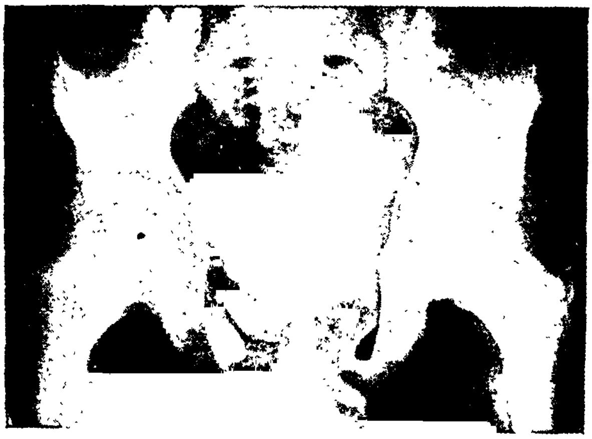

Fig. 5.—Patient, followed for eight years, with 0.5 in. shortening but no pain and no limp. Result is classed as satisfactory despite epiphysial quotient of 63. Head obviously is flatter than opposite side but if viewed alone would probably be regarded as normal.

of them may have had sufficient treatment during the vital period to at least slow down their activity and thus achieve a satisfactory or fair result many years later. This 30% did not develop the severe metaphysial changes and appeared to pass through the degenerative and regenerative phases much faster than the average. We cannot state the optimum time for full unprotected weight-bearing, but we agree with Herndon that once regeneration is started increased flattening rarely develops. We prefer to see regeneration of the outline of the femoral head before unrestricted weight-bearing is allowed in the early regenerative phase, lest too early weight-bearing lead to increased flattening of the femoral head.

It is evident from our results that treatment by bed rest and traction will insure the best results in the treatment of this disorder. It is also our contention that a patient with unilateral involvement, who can be followed closely, may be treated with a crutch and sling. Weight-bearing on the degenerating femoral head must be reduced to a minimum to get a satisfactory result. In spite of the fact that bed rest and traction have given a more uniformly satisfactory result in the treatment of this disease, we continue to use the crutch and sling. This seeming paradox arises because there are gradations in severity of this disease and when properly managed the crutch and sling method can insure satisfactory results.

Conclusions

Bed rest and traction (nonambulatory and non-weight-bearing) will insure the best results in the majority of patients with osteochondrosis of the capital epiphysis of the femur (Legg-Calvé-Perthes disease). Therapy with crutch and sling is indicated in cases of unilateral disease where instruction can be given as to the importance of non-weight-bearing methods. Inadequate treatment carries a 70% chance of causing a poor result. Ambulatory non-weight-bearing methods must be replaced with bed rest if the patient is unable to cooperate.

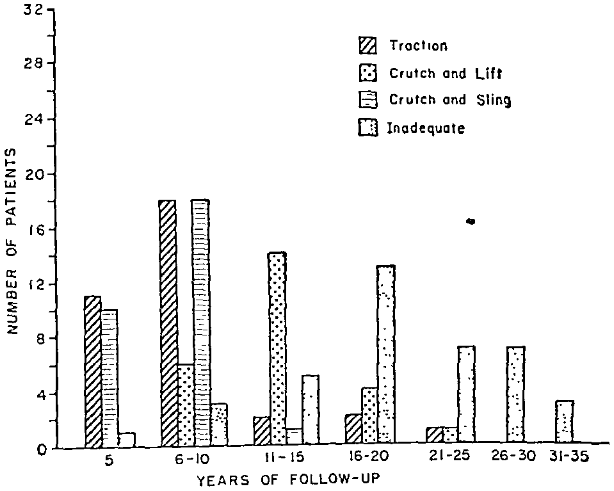

Fig. 6.—Length of follow-up in 132 patients.

600 S. Kingshighway Blvd. (10) (Dr. Stamp).

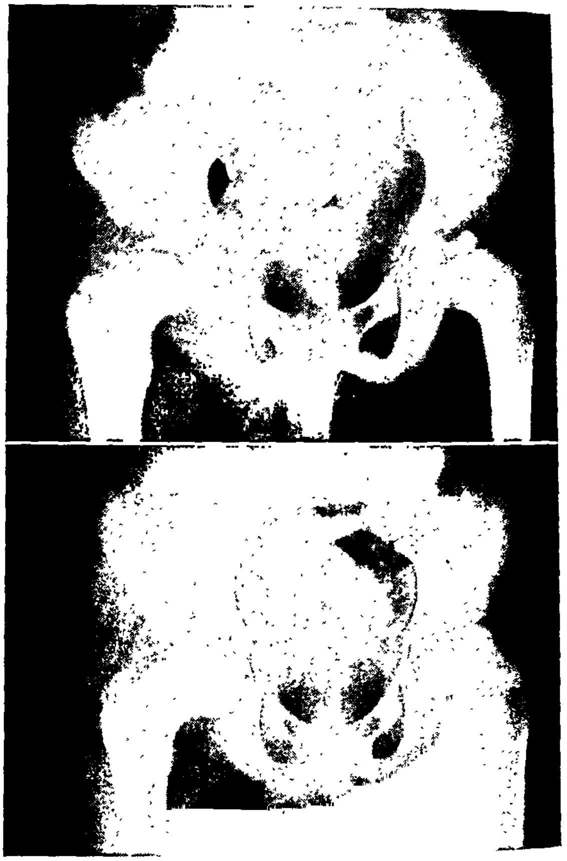

Fig. 7.—*Above,* 4½-year-old boy with pain in left hip and knee for 12 months; no treatment prior to our examination. Patient was started on bed rest and traction. *Below,* marked limitation of rotation, no pain, cystic area remaining in left femoral head. Result is presently classified as poor but may improve to fair. Epiphysial quotient is 55 on right and 45 on left.

PATHOLOGY OF JAUNDICE RESULTING FROM INTRAHEPATIC CHOLESTASIS

Hans Popper, M.D.
and
Fenton Schaffner, M.D., New York

Organic disease of the liver can cause cholestasis by mechanical hindrance at any level from the bifurcation of the common hepatic duct to the septal bile ducts within the small portal tracts; moreover, protracted cholestasis from any cause provokes enough inflammatory exudation and connective tissue formation to add a secondary intrahepatic mechanical obstructive component. The more difficult problems in differential diagnosis are presented by cases in which cholestasis occurs without tangible mechanical explanation. Certain drugs, endocrinopathies, and viral infections must then be considered as possible causes. The biliary concrements found in children with the "inspissated bile syndrome" are probably the result rather than the cause of obstructive phenomena. Liver biopsy is sometimes helpful in diagnosis, but at times surgical exploration or percutaneous cholangiography becomes necessary.

Jaundice with impairment of bile flow is said to result either from a disturbance at the site of bile formation, the epithelial cells of the liver, or from interference with the flow in the biliary passages without necessarily being associated with alteration of the liver cells. The mechanism of an obstruction to the bile flow in the extrahepatic bile ducts, for instance, by stones, tumors, or strictures, or jaundice from liver cell injury, appears obvious, and the pathological causes are established. In contrast, interference with the bile flow within the intrahepatic biliary passages is still shrouded in mystery. Although little agreement exists as to both the pathological causes and the mechanism, it might be profitable to review once more the thorny problem which has puzzled clinicians and pathologists since Naunyn's and Hanot's time and which represents one of the main difficulties in the differential diagnosis between "medical" and "surgical" jaundice. It has become more pressing in recent years because therapy with various drugs has produced this type of jaundice with increasing frequency.

Nomenclature

Interference with bile flow in the biliary passages in the liver, as clinically reflected in jaundice with pruritus, and functionally, in elevation of serum alkaline phosphatase activity, and often in total serum cholesterol activity, has been designated by various names. "Intrahepatic biliary obstruction"[1] implies a mechanical obstacle which frequently is not demonstrable. "Cholangiolitis"[2] presupposes an inflammatory process not necessarily present and usually assumed to be in the "cholangioles" by exclusion rather than by actual demonstration. "Periacinose hepatitis"[3] implies a specific localization not found in all cases. It therefore may be advantageous to use the noncommittal term "intrahepatic cholestasis"[4] until the phenomenon is better clarified. Intrahepatic cholestasis, defined functionally rather than structurally, may be the only abnormality present or the predominant one, or it may be just a component of a hepatic disease associated with damage of the liver cells with its functional characteristics.

For any attempt of localization, agreement upon the designation of the anatomic structures is required (fig. 1). The initial biliary radicles lined by the hepatic cell walls thrown into fine microvilli seen under the electron microscope are best designated as bile canaliculi or bile capillaries. They form a chicken-wire-like network separated under normal circumstances from the blood capillaries by half the width of the hepatic cell.[5] They are connected with the bile ducts in the portal tracts by narrow tubes lined by cuboid epithelium with similar microvilli. These tubes, mainly located around the portal tract and far less frequently within the lobule, are best called ductules, although the terms canal of Hering, ampulla, and intermediate pieces (Zwischenstücke) have been applied. The term "cholangioles" creates confusion, since some use it to designate bile canaliculi and others ductules or even the small septal bile ducts.

Intrahepatic Biliary Obstruction

Intrahepatic cholestasis may be produced by mechanical obstruction demonstrable by morphologic means, or it may be apparent only from its

consequences, i. e., bile imbibition without obvious structural causes. Bile pigment is found predominantly in the lobular center in the hepatic cells, usually staining protein coagulums varying in size, in bile plugs in the bile canaliculi, and diffusely staining the cytoplasm of the Kupffer cells. In prolonged jaundice, secondary liver cell injury is indicated by a *rarefication of the cytoplasm* (*feathery degeneration*) followed by loss of cells and accumulation of scavenger cells. Bile also accumulates on the lobular periphery, and sometimes proliferated ductules contain microcalculi (fig. 2).

Mechanical obstruction may be located in the larger intrahepatic bile ducts, in the small septal bile ducts within the portal tracts, or in the ductules.

Obstruction at Bifurcation of Common Hepatic Duct.—Occlusion at the forking of the common hepatic duct involves the most proximal point of the main axis of the total bile flow and thus regularly produces jaundice just as lesions of the extrahepatic biliary ducts. Although the process is actually intrahepatic, its clinical and functional manifestations are those of an extrahepatic lesion.

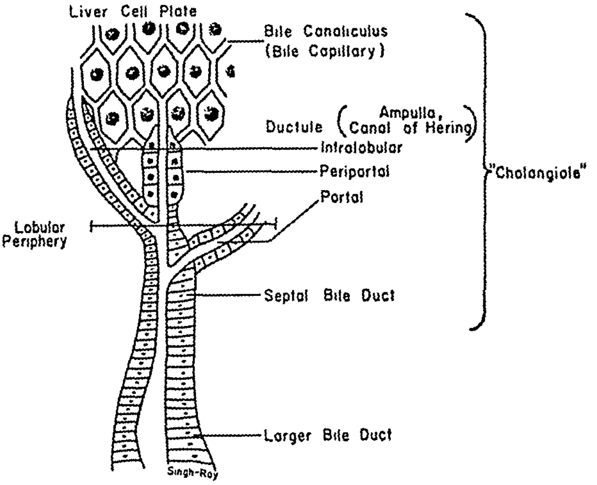

Fig. 1.—Illustration of nomenclature of intrahepatic biliary passages.

Obstruction of Larger Intrahepatic Bile Ducts.—Compromise of the lumen of one main branch of the common hepatic duct without involvement of the other, for instance, by carcinoma, by stone, or after operation, produces elevation of the serum alkaline phosphatase level but no, or only transient, jaundice because the unobstructed part of the biliary system excretes the retained bile in a compensatory fashion. Rarely is obstruction of intrahepatic bile ducts outside of the smallest portal tracts widespread enough to produce persisting jaundice. Diffuse carcinomatosis of the liver and considerable parenchymal damage complicating local obstruction are exceptions. In very rare instances, xanthomatous areas around the intrahepatic bile ducts also produce cholestasis (fibroxanthomatous cirrhosis).[6] However, space-occupying lesions may produce focal bile stasis. Thus, morphologic evidence of bile stasis in liver biopsy specimens in the absence of jaundice suggests such a lesion, particularly metastatic carcinoma.

Obstruction of Septal Bile Ducts Within the Small Portal Tracts.—In a variety of conditions, the bile flow in septal bile ducts and ductules in the portal tract may be interfered with by compression, disruption of their continuity, or alteration. The evidence that accumulation of inflammatory exudate compresses the ductules is not convincing, since large amounts of exudate may accumulate without jaundice. Leukemic infiltration of portal tracts, even if severe, is not accompanied by jaundice. Similarly, severe portal fibrosis with portal hypertension, as in schistosomiasis, or granulomas, such as in sarcoidosis, does not necessarily produce jaundice. The only reliable morphologic evidence of a biliary obstruction within the portal tract is the absence of septal bile ducts or ductules within the inflamed or scarred portal tract. This occurs on a developmental basis in the rare instances of intrahepatic ductal atresia called acholangic biliary cirrhosis.[6] Of greater importance is the disappearance of ductules and ducts which has been considered the anatomic basis of the protracted jaundice occurring mainly in older women and frequently associated with hypercholesteremia and xanthomatosis. This lesion, as the most important representative of the syndrome of primary biliary cirrhosis (see below), has been designated as pericholangiolitic biliary cirrhosis [6] (fig. 3*A*). If the ductules are present, their morphologic alterations, namely, excessive proliferation, distortion, and fibrosis around them, are not as clearly established as causes of mechanical intrahepatic obstruction because similar features can apparently be found without jaundice. Such entities as obliterating cholangitis [7] and subacute cholangiolitic biliary cirrhosis [8] belong to this group. The French author Albot [9] lists two other entities: (1) *obstructive cholangiolitis* in the course of Rössle's nonobliterating diffuse cholangitis and (2) diffuse mesenchymatous hepatitis with nodular lymphomatosis of Hanot and Kiener. Further anatomic studies should identify the morphologic appearance of ductular alterations which exert an obstructing effect. Disruption of the ductules seems also to account for relatively acute jaundice in Hodgkin's disease.

Periportal Ductular Destruction.—In prolonged cholestasis of both intrahepatic and extrahepatic types, bile imbibition of the hepatic cells on the lobular periphery is associated with degenerative changes of these cells reflected also in the presence of granules giving a periodic acid Schiff reaction even after diastase treatment. This is accompanied by some inflammatory exudation and the appearance of collagenous fibers around these cells and their neighboring ductules, all of which disintegrate. The fibers seem to aggregate, forming a continuous collagenous barrier between these liver cell plates and their draining ductules (fig. 3*B*). Therefore, in both intrahepatic and extrahepatic protracted cholestasis from any cause, a secondary intrahepatic mechanical obstructive component is added. It may account for persisting jaundice after surgical correction of a protracted extrahepatic obstruction.

The end stage of all the lesions listed is biliary cirrhosis, designated as primary biliary cirrhosis[10] if the extrahepatic biliary tract is not involved. The connective tissue may aggregate in the portal spaces or abound within the parenchyma (hypertrophic cirrhosis of Hanot). In the earlier stages, the altered reconstruction of the lobular parenchyma reflected in regenerative nodules and formation of septums connecting portal tracts and central canals is still in the background, and the manifestations of cholestasis dominate the picture. In advanced stages, all signs and symptoms of cirrhosis are present.

Intrahepatic Cholestasis Without Structurally Demonstrable Causes

Conditions falling under the heading of intrahepatic cholestasis without structurally demonstrable causes are of particular differential diagnostic importance, and far more frequent clinical examples are seen than in the group with obvious obstruction. However, the lack of an established pathogenesis permits only an enumeration of examples rather than a rational classification.

Intrahepatic Cholestatic Component of Hepatic Disease.—In almost all hepatic diseases associated with diffuse liver cell injury, the degree of jaundice may not be directly related to the degree of hepatocellular damage or that of hemolysis. In such instances it is well correlated with the degree of cholestasis as morphologically seen in the liver and with the results of hepatic tests assumed to reflect cholestasis. These are increases of serum alkaline phosphatase activity and total serum cholesterol and reduction of fecal and urinary urobilinogen. On this evidence rests the assumption that an intrahepatic cholestatic component accounts at least for part of the jaundice in various types of hepatitis and cirrhosis.[11] Between the two extremes of liver cell injury without cholestasis and cholestasis without liver cell injury, all degrees of combinations may occur in different patients and in different stages of the same disease in an individual patient.

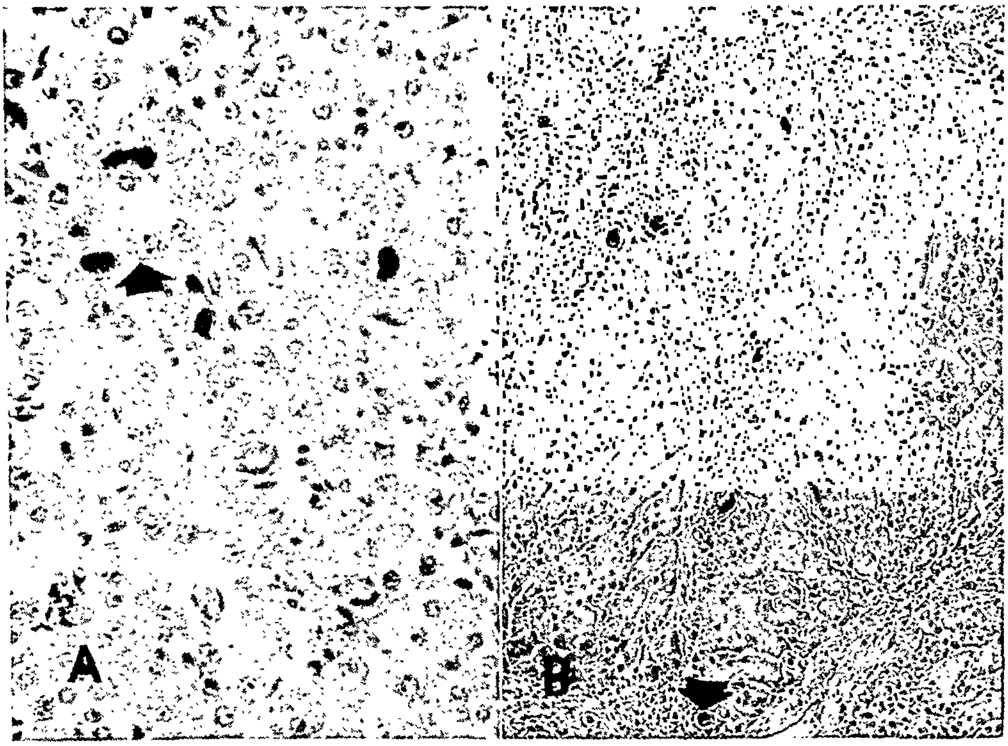

Fig. 2.—*A*, bile stasis in center of lobule reflected by presence of bile in form of various sized granules in liver cells (*arrow*), in casts in bile canaliculi, and in Kupffer cells. Hematoxylin and eosin stain (× 240). *B*, intrahepatic bile stasis in postnecrotic cirrhosis evidenced by microcalculi in proliferated ductules and in septal bile duct (*arrow*). Hemotoxylin and eosin stain (× 63).

The question of surgery because of assumed extrahepatic biliary obstruction may arise, but here liver biopsy is helpful in clarifying the nature of the disease process. In rare cases of viral hepatitis with an otherwise typical morphologic picture, cholestasis is clinically in the foreground.[12] More frequently, cholestasis predominates in one phase of an otherwise clinically typical instance of viral hepatitis.[4] Cholestatic features may also complicate large fatty livers with jaundice, diffuse septal cirrhosis, and particularly active stages of postnecrotic cirrhosis in which the deposition of microcalculi in ductules may be conspicuous. A cholestatic component may also be in the foreground of various hepatic disorders of vague etiology, such as "toxic hepatitis" occurring after operation or in the neonatal period.

Intrahepatic Cholestasis as Dominant Feature of Hepatic Disease.—Probably the most difficult differential diagnostic problems are presented by a group of cases in which cholestasis without a tangible anatomic substrate is clinically, functionally, and structurally in the foreground. Liver cell damage, if present, is relatively mild or is frequently the result of the cholestasis if feathery degeneration of liver cells is seen. In the early stages, inflammatory reactions in the parenchyma and in the portal tracts may be absent. They are regularly present after several weeks' duration and the term cholangiolitis then appears appropriate.[11] They probably are the result of the lesion rather than its cause.

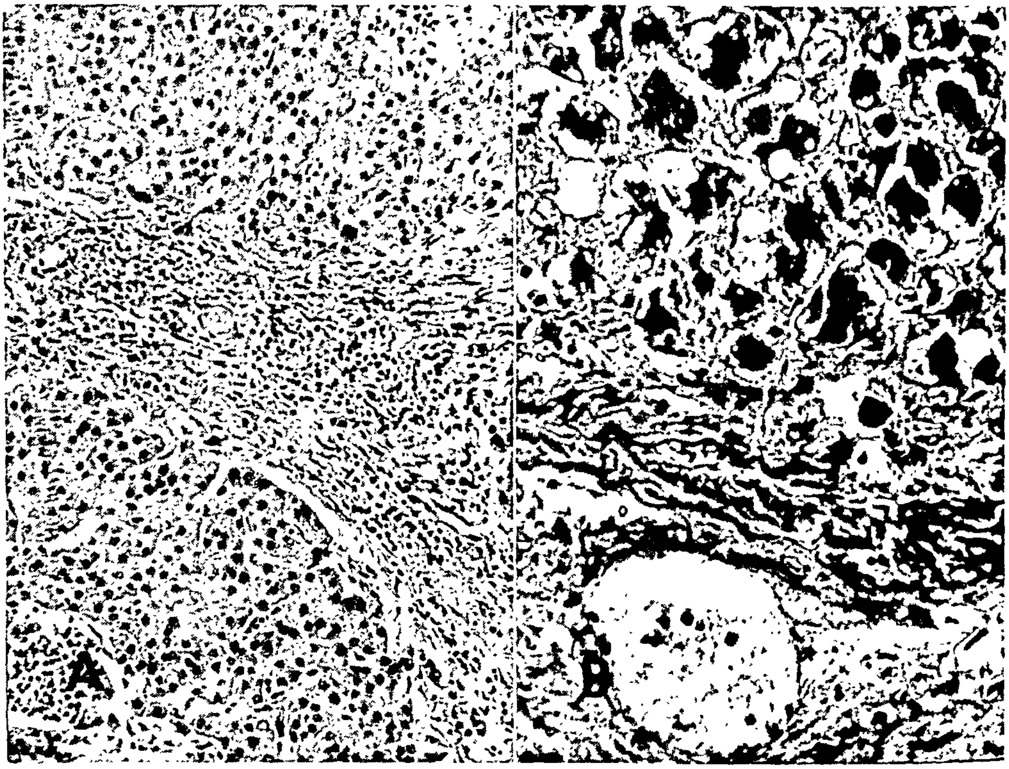

Fig. 3.—*A*, absence of bile ducts and ductules in trabeculae of pericholangiolitic biliary cirrhosis with xanthomatosis. Hematoxylin and eosin stain (× 120). *B*, aggregation of collagenous fibers on border between portal tract and parenchyma containing degenerating liver cells in secondary biliary cirrhosis after stricture of common bile duct. Mallory aniline blue stain (× 240).

In chronic stages the picture of pericholangiolitic biliary cirrhosis previously referred to may appear. However, the incidence of the progression of the cases of this group into primary biliary cirrhosis still remains to be established. In view of the absence of characteristic inflammatory changes, liver biopsy may not be of great assistance in the separation from extrahepatic biliary obstruction. It may become more helpful but also more dangerous after several weeks. Then extrahepatic biliary obstruction may have produced diffuse dilatation of the entire biliary tree. This mechanical pressure effect of hydrohepatosis is histologically reflected in the pathognomonic findings of bile infarcts and bile extravasation. Drugs of quite divergent nature chemically are reported, in increasing numbers, to produce cholestasis. In another group of cases, at present better designated as idiopathic, the etiology is unknown or at best doubtful.

Drug-Induced Intrahepatic Cholestasis: Of the various drugs producing intrahepatic cholestasis associated with little or no liver cell injury, chlorpromazine (Thorazine) seems to be the most important in recent years from the point of view of incidence.[13] In cases of intrahepatic cholestasis produced by arsphenamine,[1] chlorpromazine, para-aminosalicylic acid,[14] thiouracil, and sulfanilamide, portal infiltration has been present. In cases produced by methyltestosterone,[15] norethandrolone (Nilevar),[16] para-aminobenzoyl caffein hydrochloride, methimazole (Tapazole), and sulfadiazine, portal infiltration has not been present. Although all of the drugs produce the same structural and functional manifestations of cholestasis, only some elicit at least temporary inflammatory reactions in the portal tracts reflected in accumulation of lymphocytes, histiocytes, and segmented leukocytes, many of which are eosinophilic, associated with proliferation of ductules and circulating eosinophilia (fig. 4*A*). This lesion has been called allergic cholangiolitis [4] and has been implicated in the development of the cholestasis.

However, this portal reaction is absent, for instance, in jaundice produced by methyltestosterone [15] or norethandrolone [16] (fig. 4*B*). It may be present without jaundice in reactions produced by chlorpromazine or para-aminosalicylic acid.[14] Moreover, morphologically identical reactions may occur without previous drug therapy in random liver biopsy specimens [16] or in systemic hyperergic reactions without jaundice. In patients dying with progressive cholestasis from chlorpromazine treatment, the portal tract may be entirely normal even if preceding liver biopsies demonstrated portal reactions.[11] It thus appears that cholestasis and portal inflammatory reactions (hyperergic or not) are independent phenomena. In a very few patients exposed to chlorpromazine [17] or arsenicals,[18] transition into what has been called primary biliary cirrhosis with xanthomatosis has been reported.

Idiopathic Intrahepatic Cholestasis: The ill-defined group of patients with idiopathic intrahepatic cholestasis includes those with possible endocrine disturbances, particularly if jaundice develops during the menarche or menopause, and patients with suspected viral hepatitis,[2] at least on epidemiologic grounds, in which case it is an extreme of the condition discussed in the section on cholestatic component of hepatic disease.

Pathogenesis

Intrahepatic biliary obstruction as a mechanism producing cholestasis requires no further consideration. Since intrahepatic biliary obstruction develops in chronic stages of all forms of cholestasis, the pathogenesis of acute cholestasis in both the pure form and as a component of hepatic disease is the major problem. Much has been written about this since Naunyn assumed an alteration of the polarity of the bile flow from liver cells into the blood stream. Recent morphologic and biochemical investigations have pointed to the probable site of cholestasis although not to its mechanism. The morphologic integrity of the liver cells and the usually normal results of hepatic tests indicating hepatocellular damage as well as the presence of bile within the intraparenchymal biliary passages speak against impairment of hepatic cell function. The bilirubin in the serum gives a direct van den Bergh reaction and, therefore, interference with its glucuronide conjugation is unlikely.

Since no evidence exists for any anatomic alteration of the septal or larger bile ducts, cholestasis had been localized in the bile canaliculi or ductules (fig. 5). The possibility that an actual obstruction

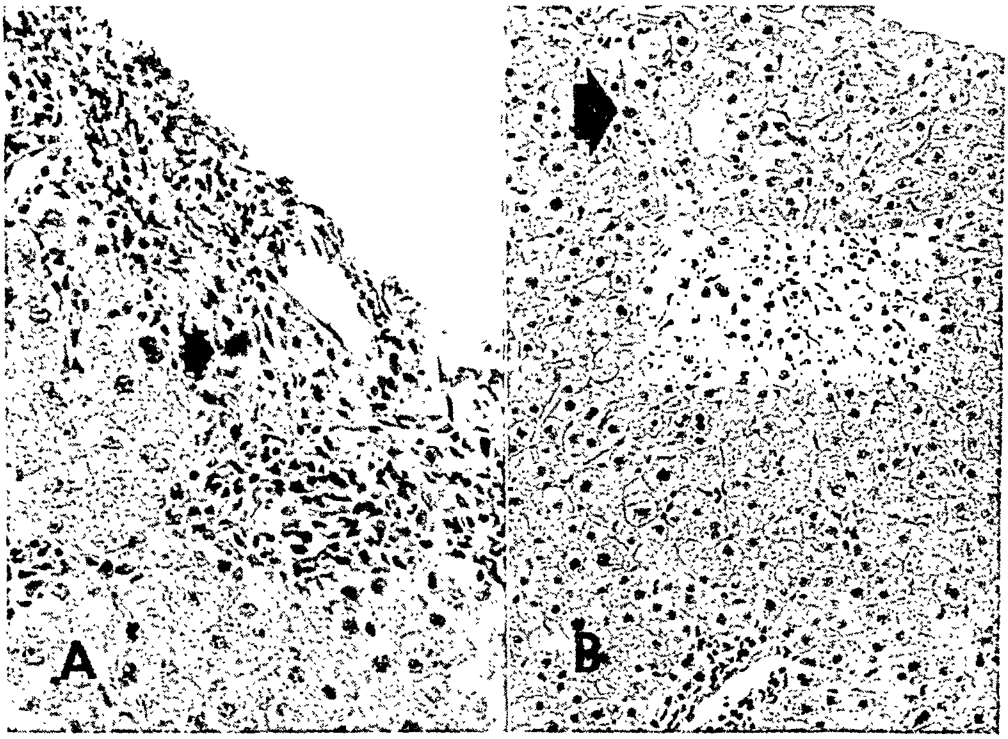

Fig. 4.—*A*, accumulation of segmented leukocytes, including many eosinophils, histiocytes, and lymphocytes and proliferation of ductules (*arrow*) in edematous small portal tract indistinctly delineated from surrounding parenchyma in liver biopsy specimen from patient with jaundice occurring after administration of chlorpromazine. Hematoxylin and eosin stain (× 240). *B*, intrahepatic cholestasis in centrolobular zone (*arrow*) in absence of alterations of portal tract in biopsy specimen from patient who had received norethandrolone. Hematoxylin and eosin stain (× 120).

exists within the bile canaliculi or ductules by either swollen, disorganized, or regenerating liver cells, or by bile plugs in the canaliculi or ductules, is negated by the presence of bile, at least in some cases, along the entire length of the bile canaliculi and ductules. Occasionally bile may even be seen under these circumstances in the form of microcalculi in the septal bile ducts. These findings suggest that the bile is inspissated or altered in its constitution. This is supported by the frequent occurrence of biliary concrements in the extrahepatic biliary ducts which gave rise to the term "inspissated bile syndrome" in children. They are more probably a reflection of altered bile rather than the cause of obstruction, especially since the biliary passages are not dilated.

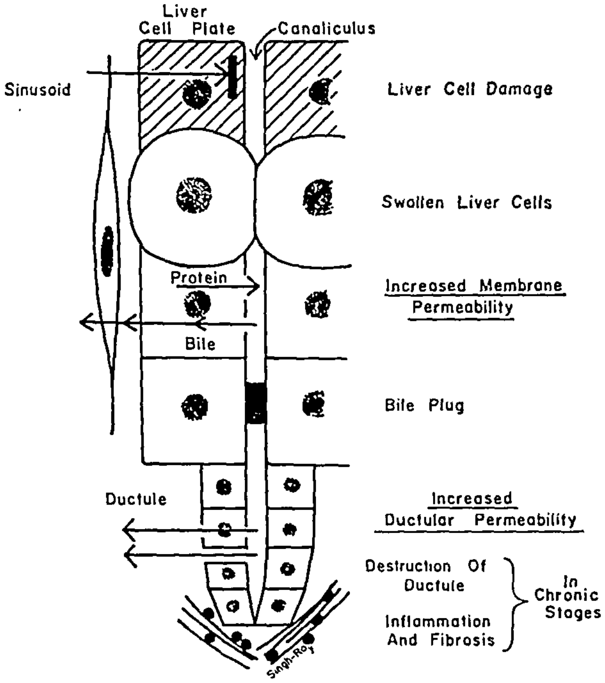

Fig. 5.—Illustration of possible mechanisms responsible for intrahepatic cholestasis.

Inflammation around the ductules and ducts in the portal tract (cholangiolitis) has already been excluded as a pathogenetic factor since it is not always present in cholestasis and may be present in the absence of jaundice. Thus, a permeability change, as previously assumed,[2] appears to account for intrahepatic cholestasis. Permeability may be increased in two opposite directions. Regurgitation of biliary substances from canaliculi or ductules may account for jaundice and possibly also for periductular inflammatory reactions. Moreover, a relatively greater backflow of fluid rather than solids may explain the dehydration and inspissation of bile with formation of bile plugs. Increased permeability in the other direction with oozing of protein from the liver cells into the bile (albuminocholia) [3] may increase the viscosity of the bile, leading to its inspissation. Material, apparently carbohydrate-protein complexes, is stained with the periodic acid Schiff reaction around bile plugs.

The alteration of the bile by possibly both dehydration and albuminocholia may best explain acute intrahepatic cholestasis. Differences in the conjugation of bilirubin in the bile deserve further study. The permeability alteration seems to be localized in the hepatic cell membrane lining the bile canaliculus and possibly also in the ductules. Further study of the microvilli visible under the electron microscope in these locations may clarify the time-worn problem of the pathogenesis of hepatogenous jaundice.

Conclusions

Intrahepatic cholestasis results from mechanical obstruction or has no demonstrable pathogenesis. The latter process seems to be a characteristic reaction of the liver to a variety of injuries. It may be only a component of a hepatic disease with structural and functional involvement of the liver cells and is, therefore, found in any type of cirrhosis or hepatitis. On the other hand, intrahepatic cholestasis may be an independent phenomenon which either is induced by drugs or is of unknown (idiopathic) etiology. The acute and subacute stages of nonobstructive intrahepatic cholestasis, more so than with demonstrable mechanical obstacles, present a difficult differential diagnostic problem because of similarity to the "surgical" type of jaundice in extrahepatic biliary obstruction. Clinical observations and hepatic tests may not provide the answer, while liver biopsy is helpful only in the presence of positive findings such as the "hyperergic" type of portal inflammation in drug-induced cholestasis or the effects of hydrohepatosis in mechanical obstruction. Surgical exploration or percutaneous cholangiography may still be a diagnostic last resort.

CLINICAL ASPECTS OF JAUNDICE RESULTING FROM INTRAHEPATIC OBSTRUCTION

F. W. Hoffbauer, M.D., Minneapolis

The various disorders associated with jaundice resulting from intrahepatic obstruction represent a major clinical problem in adult patients with icterus. Fundamentally all instances of jaundice not caused by a gross mechanical obstruction to the free outflow of bile from the liver represent intrahepatic obstruction. Popper's classification of jaundice,[1] i. e., according to impairment or nonimpairment of bile flow, is a helpful approach in discussing the mechanisms involved. In clinical practice, instances of jaundice without impairment of bile flow (jaundice associated with over-production of free bilirubin as in hemolytic disorders and retention jaundice, as in constitutional hepatic dysfunction), can usually be recognized without undue difficulty. Chronic idiopathic jaundice (Dubin-Johnson syndrome) is probably not associated with a significant quantitative reduction in total bile flow despite the mild degree of regurgitation jaundice that characterizes the condition. The diagnosis can be established by clinical study and liver biopsy. It is not customarily included in discussions of jaundice resulting from intrahepatic obstruction.

Currently drug sensitivity reactions are responsible for most instances of self-limited jaundice due to primary intrahepatic cholestasis. Icterus associated with chlorpromazine therapy represents a classic example. The development of jaundice after the drug therapy is discontinued and the occurrence of prolonged jaundice are illustrated in two patients as uncommon but noteworthy examples of this drug idiosyncrasy. In a third case, a 54-year-old man became jaundiced after four months' medication with methyl testosterone. A chronic progressive form of jaundice resulting from intrahepatic obstruction is exemplified by a 47-year-old woman with primary biliary cirrhosis of unknown etiology. The slowly increasing rise of the serum bilirubin level was temporarily reversed by steroid therapy. This effect was more likely due to the suppression of a mild concomitant hemolytic than to an effect on her liver disease. Subsequently the serum bilirubin level rose again. Death occurred after hemorrhage from esophageal varices.

From the Department of Medicine, University of Minnesota Hospital.

Read in the Symposium on Modern Concepts of Intrahepatic Obstructive Jaundice before the Section on Gastroenterology and Proctology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

Patients with impaired bile flow exhibit regurgitation jaundice; increased amounts of both conjugated and free bilirubin are present in the blood serum. The major problems in differential diagnosis are encountered in patients with regurgitation jaundice. The term cholestasis is useful in a descriptive sense for a discussion of the phenomenon of impaired bile flow in the liver itself. Cholestasis produced by extrahepatic obstruction, i. e., "surgical jaundice" due to gallstones, cancer, or stricture, usually presents a fairly well-defined clinical, biochemical, and morphologic picture. On the basis of careful clinical studies, the existence of extrahepatic biliary obstruction can be correctly predicted preoperatively in 90% of surgical cases. The problem cases encountered in the 10% group are mainly in patients who have moderately severe hepatocellular damage associated with the obstruction or who have unusual types of obstructing lesions.

Cholestasis resulting from an intrahepatic obstruction to the flow of bile presents a more formidable problem in diagnosis. Intrahepatic cholestasis is a component in the majority of patients who exhibit hepatocellular degeneration, i. e., viral hepatitis, toxic liver injury, and the various forms of cirrhosis.[1] When the component of hepatocellular degeneration predominates, a correct diagnosis of the hepatic condition can usually be established without undue difficulty. The clinical features are fairly distinctive, and the biochemical and the morphologic changes (as seen in a biopsy specimen) are revealing. Unfortunately the component "cholestasis" is not accompanied by a specific recognizable morphologic lesion; the deposition of bile pigment in the liver cells and in the canaliculi is nonspecific. Intrahepatic cholestasis may at times be the major or predominant component of a liver disorder that ordinarily is considered to be a typical example of jaundice due to hepatocellular degeneration.

Thus the physician is occasionally confronted by a patient with viral hepatitis or cirrhosis in whom the degree and duration of icterus and other evidences of biliary obstruction seem out of proportion and unusually prominent when compared with the average or classic case. This is reflected in the clinical picture; i. e., the patient may be more jaundiced than ill. It is reflected in the biochemical picture; i. e., the bilirubin, alkaline phosphatase, and lipid pattern indicate obstruction while the quantitative and qualitative changes in the serum proteins characteristic of hepatocellular damage are often minimal. Yet, even when cholestasis is a major component in cirrhosis or in viral hepatitis, an experienced pathologist can usually recognize the basic underlying disturbance by a careful study of the liver biopsy.

Gall and Braunstein[2] emphasized that in viral hepatitis the fundamental morphologic features can be recognized in biopsy specimens, even though the pathologist may not be able to predict which patients exhibit clinical or biochemical manifestations simulating excretory impairment and which patients exhibit the accepted clinical and biochemical evidences of hepatocellular degeneration. The recognition of intrahepatic cholestasis as the predominant component of certain liver disorders associated with jaundice can often be accomplished by analyzing a combination of clinical, laboratory, and histological evidences. It must be admitted that some patients do present extremely complex problems. The variables inherent in extrahepatic biliary obstruction (cholestasis with hepatocellular damage as a variable component) and the hepatitis-cirrhosis-toxic liver injury group (hepatocellular degeneration with cholestasis as a variable component) are very great indeed. At times the correct diagnosis cannot be established until the exact status of the extrahepatic bile duct system is determined.

In certain patients cholangiography must be performed. In these complex situations the safest course is to treat the patient as a medical problem for four to six weeks before resorting to operation. The arbitrary period of study and medical treatment of these diagnostic problem cases admittedly constitutes a hardship for the patient who ultimately proves to have a surgical lesion. However, it is likely to be lifesaving for the patient with medical jaundice in whom early surgical intervention is not only unrewarding but actually hazardous.

Jaundice due to intrahepatic obstruction is not limited to patients with hepatocellular degeneration, i. e., cirrhosis, viral hepatitis, or toxic liver injury. Manifestations of cholestasis may be the sole component discernible in certain liver disorders in which the liver cells appear normal and the extrahepatic duct system is completely patent, i. e., primary intrahepatic cholestasis. The patient with jaundice due to chlorpromazine sensitivity is a classic example. A number of drugs have been incriminated in the hypersensitivity reactions that produce primary intrahepatic cholestasis. In rare instances no cause can be definitely established.

The basic mechanism involved in primary intrahepatic cholestasis is unknown. If a single mechanism is involved, it is presumed to be a regurgitation of bile back through morphologically intact "cholangioles." (The term cholangiole has been used broadly to include the biliary canaliculi, the ductules, and the terminal ducts.[3] As used in current American literature the term presumably includes the ductules—intralobular and perilobular ducts—and the interlobular ducts, but not the canaliculi.) One must assume that a functional derangement in the cholangioles permits biliary substances to leak back into the tissues and eventually to regurgitate into the lymph and blood. This explanation is invoked to account for the presence of bile thrombi in the canaliculi up to but not beyond the ductules, the apparently normal histological appearance of the ductules and ducts and the pericholangiolitis. The inflammatory reaction is presumably due to irritation produced by substances in bile.

The explanation has been offered that an increased permeability of the cholangioles favors an increased absorption of water with a resultant inspissation of bile. The occurrence of bile plugs or thrombi, so prominent in intrahepatic cholestasis, is thought to be on this basis. Bile thrombi themselves are not believed to be the fundamental cause of the intrahepatic obstruction. One must accept the fact that the morphologic evidences of cholestasis, i. e., the bile staining, the bile plugs, the inflammatory reaction, and the evidences of parenchymal cell injury (usually very minimal and insignificant in primary intrahepatic cholestasis) are probably secondary to the stasis of bile rather than its cause.

The critical student of the subject may not be entirely satisfied with the explanation that a functional impairment of the cholangioles, i. e., an increased permeability, is responsible for jaundice due to intrahepatic obstruction. This has been regarded as a plausible explanation to account for the available biochemical and histological observations. The inability to produce a liver lesion in an experimental animal that completely mimics primary intrahepatic cholestasis as seen in man is a distinct handicap in fundamental investigations of this important subject. The experimental studies of Hanzon[4] dealing with basic mechanisms involved in regurgitation jaundice did not indicate that the ductules or ducts exhibited an undue vulnerability as a site of bile escape. In graded liver cell injury and in the early stages of extrahepatic obstruction, regurgitation of bile (visualized by virtue of fluorescent uranin) was observed to occur directly from intact canaliculi and from morphologically intact liver cells.

The apparent absence of a specific morphologic lesion in primary intrahepatic cholestasis disturbs the pathologist in his attempts to explain the pathogenesis of the disorder. The absence of a specific lesion also constitutes a very real obstacle in the practical problem of establishing the diagnosis on the basis of a liver biopsy specimen. The similarity of the histological appearance of the liver irrespective of whether cholestasis is due to intrahepatic or extrahepatic obstruction has been emphasized repeatedly. At times the hydromechanical effects of extrahepatic obstruction are sufficient to produce specific morphologic changes that have diagnostic value. However, when liver biopsies are performed early, i. e., within the first two or three weeks of the onset of jaundice, the pathologist may not be able to make the distinction.

Primary intrahepatic cholestasis presents a clinical picture that may be easily confused with some forms of extrahepatic biliary obstruction, since the features are often those of icterus and pruritus without signs of toxicity or sepsis. The liver tests are not usually distinctive; the alkaline phosphatase and lipid levels are elevated in both conditions, and the abnormalities in the proteins (quantitative or qualitative) are usually minimal in each type. Fortunately, many instances of intrahepatic obstruction, especially cases of drug-induced jaundice, are self-limited and soon relent. A correct diagnosis can often be established during the course of clinical observation and medical treatment. Occasionally cases of protracted jaundice due to primary intrahepatic cholestasis are encountered, and an operative cholangiogram may be required to establish the diagnosis with absolute certainty. In selected instances this may be performed under local anesthesia through a small abdominal incision.

Acute (Self-Limited) Forms of Jaundice Resulting from Intrahepatic Obstruction

Drug reactions are responsible for the majority of instances of primary intrahepatic cholestasis that are currently encountered in clinical practice. The characteristic histopathological and biochemical features of this type of reaction were described in 1940 by Hanger and Gutman in cases of arsphenamine sensitivity, and in the ensuing 18 years[5] a number of other drugs have been incriminated as causative agents. Jaundice due to chlorpromazine has been the most common cause of this reaction in recent years.

Jaundice due to Chlorpromazine.—The incidence of jaundice due to chlorpromazine (Thorazine) hydrochloride is stated by the manufacturer to be "low," but in view of its administration to more than 10 million patients, even a low incidence of this reaction results in a large number of individuals with icterus. There have been many opportunities to study the problem; the literature has been reviewed in recent reports.[6] Although the pattern of reaction has varied somewhat, the majority of patients develop jaundice during the second or third week of the drug administration. The onset of jaundice is often preceded by three or four days of prodromal symptoms that include fever, malaise, anorexia, and indefinite gastrointestinal symptoms. At times patients experience mild degrees of abdominal pain at the onset. The jaundice is typically obstructive in type with dark urine and light stools.

With the onset of jaundice many of the symptoms disappear, and, save for pruritus, the patients become relatively comfortable. The prostration that usually attends viral hepatitis is customarily lacking in patients with jaundice due to chlorpromazine. Fortunately, the intrahepatic obstruction to bile flow usually relents within a few weeks to two months, and the patients recover uneventfully. Although most observers regard the disorder as a hypersensitivity phenomenon, there are many aspects of the problem that remain obscure. In a few patients the drug can be administered again without producing a recurrence of icterus, and yet in other patients an exquisite hypersensitivity to the agent has been demonstrated.

The histopathology of jaundice due to chlorpromazine is characteristic and represents the typical picture of primary intrahepatic cholestasis. The findings usually observed are centrolobular bile staining, bile casts or plugs predominately centrolobular in location, and minimal evidence of periportal or periductular inflammation. When present, the latter is usually nonseptic in character. The occasional occurrence of some eosinophils scattered among the round cells in the infiltrate lends weight to the concept that the reaction may be allergic in nature.

The laboratory tests in jaundice due to chlorpromazine follow a fairly uniform pattern in the majority of cases. The regurgitation jaundice that occurs is characterized by elevations of both direct and indirect reacting types of serum bilirubin. The degree and duration of the hyperbilirubinemia varies greatly. An increase in the level of the alkaline phosphatase is an almost constant phenomenon; this often precedes the elevation of the serum bilirubin level.[7] The cephalin cholesterol flocculation test, the thymol turbidity reaction, and similar liver tests are usually normal in chlorpromazine-induced jaundice.

Several unusual aspects of the chlorpromazine-induced jaundice problem warrant comment. The occurrence of jaundice some days after the drug therapy has been stopped deserves emphasis. Cases have been described in which jaundice developed 14 to 19 days after chlorpromazine therapy had been discontinued, even though the patient had received the drug for only 5 or 6 days.[8] The diagnosis of intrahepatic cholestasis was confirmed by a liver biopsy secured at the time of operation. In each instance the common bile duct was patent. The apparent late development of jaundice after chlorpromazine therapy has been discontinued has also been witnessed in a patient on the medical service of the University of Minnesota Hospitals. In this instance jaundice was first noted approximately three weeks after the drug was withdrawn. The icterus reached its peak in another three weeks and gradually relented. Icterus lasted approximately two months. The patient was admitted late in the course of the illness, and a liver biopsy was not deemed necessary.

A review of the available liver tests that had been performed indicated the rather characteristic pattern exhibited by patients with chlorpromazine-induced jaundice. Throughout the period of icterus, the bilirubin, phosphatase, and the serum lipid levels were elevated and the cephalin-cholesterol flocculation and thymol turbidity test remained normal. Although the diagnosis was not established with absolute certainty, the clinical course strongly suggested a delayed drug reaction as the cause of jaundice. Such episodes are admittedly uncommon, but they do emphasize the need for a careful inquiry regarding use of recent drugs in all jaundiced patients.

In a few reported instances, jaundice due to chlorpromazine has been very protracted. A remarkable example was reported by Myers and associates.[9] A man, aged 31, developed jaundice and pruritus after receiving the drug for two weeks. He remained jaundiced for 20 months. Five months after the onset of icterus, the patient developed many of the characteristic features of primary biliary cirrhosis, including extensive xanthomata and splenomegaly. Eventually the marked hypercholesterolemia declined and the xanthomata disappeared. Though the patient's jaundice entirely cleared, the spleen remained enlarged and fear was expressed that his cirrhosis might yet progress. Instances of prolonged jaundice due to chlorpromazine have been observed by others. In one reported series,[10] a patient remained jaundiced for 13 months, and a second patient who became jaundiced during early pregnancy remained icteric for eight and one-half months.

I have had an opportunity to see in consultation one patient in whom jaundice lasted for an entire year. The patient received chlorpromazine in the treatment of severe vomiting during the first trimester of her pregnancy. Jaundice developed 17 days after the drug therapy was first started. The patient's jaundice persisted throughout her pregnancy. After an uneventful delivery in December, 1956, the icterus increased in intensity and was followed by a rise in the blood cholesterol level. Fortunately a gradual remission occurred, and by July, 1957, the jaundice had virtually disappeared. Whether or not protracted jaundice is more prone to develop when this form of drug sensitivity occurs during pregnancy is not known. It would seem a wise precaution to discontinue use of the agent very promptly in any pregnant woman receiving chlorpromazine when even a slight rise in the serum phosphatase or bilirubin level indicates the possible onset of this drug reaction.

Jaundice due to Methyl Testosterone.—The clinical and histological observations in patients who have developed jaundice during the course of methyl testosterone therapy have been described by several observers.[11] The following case, studied with other physicians in 1951, illustrates the occurrence of intrahepatic biliary obstruction in a patient who received methyl testosterone orally for a period of four months.

Case 1.—A 54-year-old white man was admitted to the medical service of Drs. Altnow and Bowers at the Eitel Hospital in Minneapolis, March 27, 1951. The patient was referred for study and treatment of jaundice that had been present for one month. The patient had experienced mild indigestion and fatty food intolerance for the preceding two months. Physical examination revealed a deeply jaundiced man; the liver was palpable just below the costal margin. There were no stigmata of cirrhosis present. Routine laboratory studies yielded normal results. The icteric index was 130 units; the prothrombin time was 41% of normal. After a single injection of vitamin K the prothrombin time returned to normal. The stools appeared acholic.

On March 29, a surgical exploration was carried out by Dr. W. I. Nelson. The liver was found to be smooth but deeply bile stained. The gallbladder and bile ducts were collapsed but patent. A T-tube was inserted into the common duct, and a cholangiogram was secured. This revealed that the larger intrahepatic ducts were patent and a free flow of contrast media through the common bile duct into the duodenum was demonstrated. A biopsy of the liver was secured at the operation. Postoperatively small amounts of bile appeared in the T-tube after several days. The patient's jaundice persisted for some time. The T-tube was removed after two weeks.

The liver biopsy revealed bile staining most marked in the center of the lobules. A minimal degree of liver cell damage was apparent in the centrolobular portion where slight disorganization of the cell plates was evident. In general, the architecture of the liver was well preserved. Although numerous bile thrombi were seen, no "bile lakes" were noted. The larger bile ducts were empty. Inflammatory exudate was inconspicuous. The pathologist, Dr. Craig Freeman, termed the lesion an intrahepatic obstruction of unknown etiology. Further inquiries regarding antecedent drug therapy were made. It was learned from the referring physician that the man had received methyl testosterone, 15 mg. per day, from October, 1950, to February, 1951. The medication was discontinued with the onset of jaundice.

Two weeks after operation a series of liver tests was repeated. These were secured during the eighth week of the patient's jaundice, and the results were as follows: serum bilirubin level (one minute) 5.4 and (total) 8.5 mg. per milliliter; cephalin-cholesterol flocculation, negative; thymol turbidity, 1 unit; zinc turbidity, 8 units; serum alkaline phosphatase level, 27.6 King-Armstrong units; serum cholesterol level, total, 298 mg. per 100 ml.; and feces urobilinogen level, 51 mg. per day. The patient's jaundice slowly receded; on May 20, 1951, the total serum bilirubin level was 2.7 and the total cholesterol level, 288 mg. per milliliter. The patient made an uneventful recovery, and the jaundice disappeared by July, 1951. The patient has remained well subsequently.

It seemed evident that this patient developed painless jaundice as a result of intrahepatic cholestasis brought about by a drug hypersisitivity reaction. In most of the reported instances of jaundice associated with methyl testosterone, icterus has appeared after two or three months of therapy. This unusual and admittedly uncommon reaction seems to be limited to patients receiving methyl testosterone; as far as is known it has not been reported in patients receiving testosterone propionate.

Methyl testosterone may be given to relieve itching in patients who have obstructive jaundice.[12] In my experience this usually causes a further rise in the serum bilirubin level. The mechanism by which this agent acts on the liver is unknown. In selected patients with jaundice, methyl testosterone may be administered in an attempt to relieve pruritus, provided such patients are willing to accept the risk of increasing icterus and probable aggravation of any existing tendency toward edema formation. To some patients with intolerable itching this price they must pay for relief of their distress does not seem too high. The following case illustrates the aggravation of the jaundice concomitant with the relief of the pruritus in a patient with secondary (cholangitic) biliary cirrhosis.

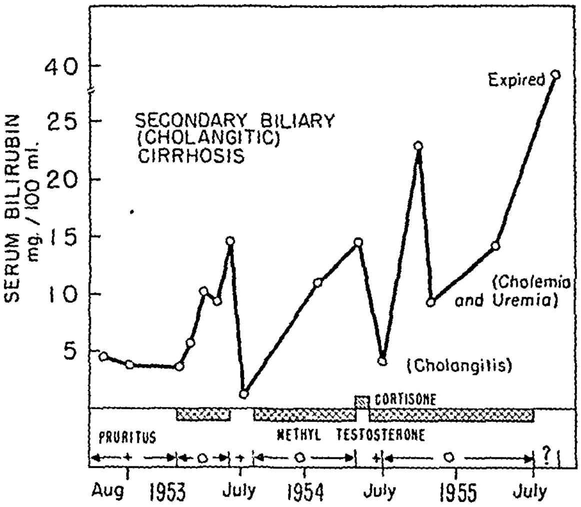

Fig. 1 (case 2).—Jaundice and severe pruritus in patient with biliary cirrhosis. Oral methyl testosterone therapy relieved itching but was accompanied by increase in degree of icterus.

Case 2.—A 69-year-old woman suffered an injury to the common bile duct at the time of a cholecystectomy performed by her private physician in 1950. After a stormy postoperative course the patient developed marked jaundice. Five months later an experienced surgeon operated on the patient and succeeded in anastomosing the right and left hepatic ducts directly to the duodenum. Eighteen months later the patient had an episode of ascending cholangitis. She was first treated at the University of Minnesota Hospitals in August, 1952. After intensive antibiotic therapy and drainage of a right subphrenic space abscess, the patient recovered; low-grade jaundice and intense pruritus persisted. In February, 1953, the patient was given methyl testosterone in amounts sufficient to control her pruritus. This usually amounted to 20 mg. per day.

As shown in figure 1, the patient did obtain relief of her pruritus, but the serum bilirubin level rose. When the drug therapy was discontinued, the jaundice receded and the pruritus returned. These observations were repeated again in 1954. The drug therapy was discontinued in May, 1954, and the patient received cortisone for one month. Although the serum bilirubin level fell, the rate of decline was no faster than previously noted without cortisone. The development of gastrointestinal distress and bleeding necessitated the discontinuing of cortisone therapy. The patient's final year of life was marked by recurrent attacks of cholangitis; this made it difficult to determine how much of the elevation of the serum bilirubin was due to the administration of methyl testosterone and how much to an aggravation of her underlying disease. She eventually developed cholemia and uremia and died.

The case illustrates the aggravation of a preexisting jaundice when methyl testosterone was given to obtain relief of distressing pruritus.

In addition to the agents mentioned, other drugs have been held responsible for the occurrence of jaundice resulting from intrahepatic obstruction. The incidence of such reactions has been far less than with chlorpromazine. The experiences emphasize the need for a careful evaluation of drugs recently administered when one first examines a jaundiced patient. Jaundice due to intrahepatic obstruction resulting from a drug sensitivity reaction may so closely mimic obstructive jaundice produced by gallstone or tumor that the examiner may easily be misled.

An occasional patient with viral hepatitis may exhibit features of prolonged regurgitation jaundice and thus simulate bile duct obstruction. The value of needle biopsy of the liver in establishing the existence of viral hepatitis as the underlying or fundamental disorder in such patients has been recently emphasized.[13] The histopathological changes may not be correctly interpreted unless the specimen is examined by an experienced pathologist who has taken a particular interest in this type of differential diagnosis.

Chronic (Progressive) Forms of Jaundice Resulting from Intrahepatic Obstruction

A classic example of a chronic form of intrahepatic obstructive jaundice is represented in the patient with primary biliary cirrhosis.[14] The victims of this disorder are usually well-developed, well-nourished, middle-aged women who exhibit melanotic pigmentation of the skin. On examination the sclerae are often found to be icteric and the liver enlarged, readily palpable, but seldom tender. The spleen is also enlarged. The skin over the arms and legs, thickened and revealing evidences of self-inflicted scratch marks, attests to the presence of prolonged pruritus. Such patients may or may not exhibit xanthelasma and xanthoma.

The case histories of 30 adult female patients studied at the University of Minnesota Hospitals during the 12-year period 1945 to 1956 have been recently reviewed. In each instance most of the typical features of primary biliary cirrhosis existed. Because of the relative rarity and long duration it is difficult to witness the entire natural course of this chronic disorder in more than a few instances. In the cases reviewed there was no conclusive evidence that a single entity was represented, despite the similar clinical findings exhibited by most of the patients. Nearly all students of the disease have observed its striking predilection for adult women.

The disease often begins so insidiously that it is difficult to determine the onset. This was estimated to be before age 40 in eight instances in the series reviewed; 15 patients appeared to develop the disease between the ages of 40 and 60 years. Three were beyond the age of 60 years when the first symptoms appeared. The exact time of onset could not be determined in four cases. No clear-cut relationship to menses, to pregnancy, or to the menopause was evident. The estimated duration of the disease was from 3 to 16 years in the patients who could be followed.

The existence of primary biliary cirrhosis can be suspected on the basis of the characteristic symptoms of fatigue and pruritus and the physical signs of pigmentation of the skin and enlargement of the liver. It should be emphasized that detectable jaundice may not develop until some time after the onset of the disease. A pathological diagnosis can usually be established during life if an adequate liver biopsy specimen can be obtained. The earliest lesion that can be recognized is a pericholangiolitis, initially associated with bile ductule proliferation. Later the number of bile ductules appears to decrease, and the pathological findings in the liver become increasingly complex as the disease advances.[14]

The etiology of the disease is unknown; MacKay's recent observations [15] offer promise of new insight into this obscure illness. In the majority of instances the disorder appears to be relentlessly progressive once it is established. The late stages are characterized by evidences of portal hypertension and hepatic insufficiency. At present, no specific remedies are known; treatment must be symptomatic and supportive. The clinical management of the patient with primary biliary cirrhosis poses a very difficult problem for the attending physician. In the early phase of the disease, a phase which incidentally may last 3 to 10 years, the problems of the control of itching and fatigue are prominent. In some patients the prolonged elevation of the blood cholesterol level leads to xanthoma formation, with its associated discomfort and disfigurement. As the disorder progresses and slow deterioration of liver function becomes manifest, the elevated blood lipid levels often diminish. The prolonged exclusion of bile from the intestine in some instances may lead to skeletal demineralization. Severe bone pain was noted in three of the patients studied in the present series of 30 cases. Each patient obtained some relief from bone pain when the calcium and vitamin D intake was augmented.

The late phase of the clinical course of primary biliary cirrhosis is marked by the problems of liver insufficiency with edema and ascites formation. Portal hypertension and the occurrence of hemorrhage from esophageal varices is a prominent feature in some instances. The following case has been selected from the series reviewed to illustrate this point and also to emphasize another feature. In assessing the significance of the degree of jaundice in any given patient, it is necessary to consider the total daily pigment production and the excretory ability of the liver. In most of the common forms of cirrhosis, for example, a primarily fatty cirrhosis in an alcoholic patient or an idiopathic postnecrotic cirrhosis in a young woman, an increase in the depth of jaundice usually signifies increasing parenchymal cell damage and is an ominous sign.

In primary biliary cirrhosis, during the early phase at least, the depth of jaundice does not necessarily reflect the same degree of liver cell impairment but rather the inability of the intrahepatic biliary system to excrete the daily bilirubin load. Such patients are barely able to excrete the normal daily load of bilirubin produced by the normal daily rate of red blood cell destruction. If there is even a slight increase in the daily production of bilirubin, i. e., a mild hemolytic process related to the presence of congestive splenomegaly, the degree of jaundice may become quite intense. The depth of jaundice must be considered in relationship to the factors of bilirubin production and the impaired ability of the liver to excrete pigment.

Case 3.—In February, 1955, this 47-year-old woman was referred to the medical service of the University of Minnesota Hospitals because of chronic jaundice, pigmentation, and pruritus. The patient had first consulted a physician in August, 1954; jaundice was observed and bed rest advised on the presumptive diagnosis of hepatitis. There were no known contacts with cases of viral hepatitis in the community, and none had occurred in the family. Six weeks of bed rest failed to produce an alteration in the status of the patient. In October, 1954, she was more thoroughly investigated because the low-grade jaundice persisted. Cholecystography was performed; this revealed a normally functioning gallbladder. A needle biopsy of the liver was interpreted by the pathologist as showing "benign low grade hepatitis." The blood serology report at this time was "V.D.R.L. doubtful positive 1-16" and "Wassermann doubtful positive." The patient's condition remained unchanged despite various measures used.

The admission examination of the patient in February, 1955, revealed an icteric and pigmented woman in no apparent distress save for pruritus. The liver and the spleen were palpable. No ascites was noted. Skin lesions on the legs were considered to be those of lichen planus; this diagnosis was subsequently confirmed by skin biopsy. The patient was closely questioned regarding antecedent jaundice; she admitted that she might have been jaundiced as long ago as 10 years before (at age 37) and the pigmentation and pruritus had begun, insidiously, some time before 1955. The presence of esophageal varices was demonstrated on x-ray examination.

Laboratory studies at the time of this admission revealed the following values: hemoglobin level, 13.3 Gm. per 100 cc.; red blood cell count, 4,300,000 per cubic millimeter; hematocrit reading, 38%; reticulocyte count, 0.5%; white blood cell count, 3,100 per cubic millimeter; and differential count, normal. The results of the liver tests were as follows: serum bilirubin level (one minute and total), 1.3 and 3.7 mg., respectively, per 100 ml.; alkaline phosphatase level, 82 and 45 units (King-Armstrong method) on two studies; cholesterol level, 249 mg. per 100 ml.; cephalin-cholesterol flocculation, 3+; and thymol turbidity, 11 units. The total serum protein level was 7.1 Gm. per 100 ml. (albumin 3.2 and globulin 3.9). The prothrombin time was normal. The fecal urobilinogen level was 507 mg. per day. A bone marrow biopsy disclosed normoblastic hyperplasia and an increased number of megakaryocytes.

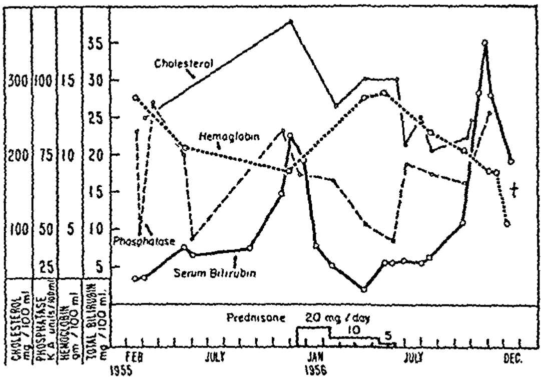

Fig. 2 (case 3).—Primary biliary cirrhosis and hypersplenism. Hemoglobin level rose and bilirubin level declined during period of treatment with steroid. Decrease in jaundice was more likely due to suppression of mild concomitant hemolytic process than to primary effect on liver. Cholesterol level was not significantly affected. Fluctuations in phosphatase levels could not be correlated with any therapeutic agent administered.

Peritoneoscopic examination was performed by Dr. J. B. Carey Jr. The liver appeared coarsely nodular and enlarged. A liver biopsy was reported by the hospital pathologist as indicating "portal cirrhosis." The patient was discharged with a clinical diagnosis of primary biliary cirrhosis and followed in the outpatient department.

The significance of the elevated fecal urobilinogen excretion in the presence of impaired excretory function on the part of the liver was not appreciated. This undoubtedly reflected an increased rate of erythrocyte destruction related to hypersplenism. The patient's condition remained virtually unchanged. Antihistaminics and lotions failed to relieve the pruritus; but except for this discomforting symptom the patient felt well. Her appetite and strength remained satisfactory, and she continued to carry out all of her household duties. In June, 1955, the patient was readmitted to the hospital for a lumbar puncture; the blood serology tests again showed positive results (V.D.R.L., + diluted; Kahn, 3+; Hinton, 4+) in May, 1955. The cerebrospinal fluid was entirely normal, and the spinal fluid (Wassermann) was negative. The treponema pallidum immobilization test, submitted to the Venereal Disease Research Laboratory in Chamblee, Ga., was reported as "nonreactive." In view of the entirely negative evidence for syphilis, the serologic tests were considered to have given biological false-positive reactions. An L.E. clot test was negative at this time.

The physical examination at the time of the second hospital admission revealed no essential change from that observed earlier. The laboratory values remained essentially unchanged (fig. 2); the hemoglobin level had declined somewhat. Although further evidence of hemolytic activity was not sought, the effect of the congestive splenomegaly was suggestive in that the leukocyte count was 2,750 per cubic millimeter, though the differential count was normal. The platelet count was 104,000 per cubic millimeter. The patient was again discharged, and her course was followed in the outpatient department.

As shown in figure 2, the serum bilirubin level gradually rose throughout the 10 months after the patient's original investigations. In December, 1955, the patient was readmitted for the third time for reevaluation. The degree of icterus was intense. The hepatosplenomegaly was again demonstrated. The patient's only complaints were related to pruritus and mild fatigue. The values for the liver tests were similar to those obtained initially. The hemoglobin level was 9.4 Gm. per 100 ml. Evidence of mild hemolytic activity (reticulocyte counts 1.9 and 4.6%) and an elevated fecal urobilinogen level (360 mg. per day) were demonstrated. The leukocyte count was normal (5,200 per cubic millimeter), and a normal differential count was recorded. The platelet count was 184,000 per cubic millimeter.

The administration of prednisone, 20 mg. per day, was begun during this admission, and the patient was discharged on this therapy to be followed in the outpatient clinic. The icterus declined, as can be seen from the values shown in figure 2. Initially, the patient did seem to be somewhat relieved of her troublesome pruritus, although the results were not dramatic. Despite dietary salt restriction the patient experienced fluid retention while receiving steroid therapy. She complained of epigastric distress; this discomfort was only partially relieved by an antiulcer regimen. A search was made for x-ray evidence of an ulcer, but none was demonstrated. In April, 1956, the itching was again as severe as formerly, even though the degree of icterus was greatly decreased. Methyl testosterone, 10 mg. per day, was added to the regimen during May, 1956. This afforded little subjective relief but did aggravate the problem of fluid retention. In June, 1956, prednisone therapy was discontinued. During the ensuing months, several other agents were used in an attempt to relieve the pruritus. They proved ineffectual.

In November, 1955, the patient was admitted to the hospital for the fourth time. The jaundice was again intense, but in other respects the patient's general condition remained relatively satisfactory. Clear-cut evidence of hemolytic activity was obtained at this time in a study conducted by Dr. A. Sigrid Gilbertson. The half-life of the patient's chromium-tagged red blood cells was shown to be only 12 days as compared to a normal of 25 to 30 days. A splenectomy and spleen-renal anastomosis was advised. The patient requested that this be postponed until after the Christmas holidays. This seemed to be a reasonably safe request to grant in view of the apparent well-being of the patient and the chronic nature of her illness. She was permitted to return to her home in rural Minnesota.

Unfortunately the patient experienced a massive hemorrhage from esophageal varices on Dec. 26, 1956. She was subsequently returned to the University Hospital. Despite multiple transfusions and esophageal tamponade the patient continued to bleed massively and remained in a shock-like state. In desperation, an emergency operation was performed and an attempt made to ligate the bleeding esophageal varices by a transthoracic approach. The patient was in a critical condition preoperatively and failed to rally. She died the next day. An autopsy examination revealed cirrhosis, esophageal varices, splenomegaly, ascites, and bilateral hemothorax, most marked on the left side. The spleen weighed 900 Gm. and exhibited congestive changes. The liver weighed 2,540 Gm. and was deeply bile stained and nodular. The gallbladder and bile ducts were normal. Microscopic sections of the liver revealed the characteristic architectural alterations of cirrhosis. The pathologist reported a diminished number of small bile ducts in the fibrous septums. The larger intrahepatic bile ducts were not believed to be abnormal.

This case illustrates a number of features that occur in primary biliary cirrhosis. It is possible that the disease actually began some time before the patient first consulted a physician. The manifestations of the disease were well advanced when the patient was first admitted in February, 1955, since hepatosplenomegaly, pigmentation, and demonstrable esophageal varices already existed. There was suggestive evidence of a slight increase in the rate of erythrocyte destruction even then, though its significance was not appreciated. The slight elevation of the fecal urobilinogen level in a patient with evidence of impaired ability of the liver to excrete bilirubin was such an indication. The slow rise of the serum bilirubin level over a period of the next 10 months (fig. 2) reflected an imbalance between the daily pigment load and the ability of the excretory system to fully meet these demands.

In view of the complexity of such cases it is not at all surprising that the true significance of a gradually rising bilirubin level was incorrectly interpreted and the assumption made that the patient's liver function was seriously decreasing. The trial of steroid therapy was commenced in December, 1955, with the thought that this might possibly reduce the intrahepatic obstruction. In retrospect, the decrease in the serum bilirubin level that occurred between December, 1955, and June, 1956, was more likely due to a suppression of the patient's mild hemolytic activity rather than any primary effect upon the liver. Presumably, the liver was able to cope with a moderate bilirubin load but could not quite keep pace with a moderately increased work load.

The decision to advise a splenectomy and spleen-renal anastomosis should have been reached earlier. It is difficult to advocate a shunting operation as a prophylactic measure in patients with esophageal varices before an episode of bleeding has once occurred. This is especially true in patients with cirrhosis where the operative mortality is appreciable. If the patient survives the first episode of bleeding, the victim and the family are in a much better position to understand the hazards imposed by the presence of varices and the need for taking the necessary operative risk to forestall future episodes. Unfortunately the initial episode of bleeding may prove fatal, as in the case just cited.

In instances of cirrhosis and congestive splenomegaly, consideration should be given to the additional effect of hypersplenism with its attendant hemolytic activity, leukopenia, or thrombocytopenia in the decision regarding prophylactic shunting operations. When a patient with x-ray evidences of esophageal varices exhibits signs of hypersplenism, there may be reason to adopt a bolder attitude and to advise splenectomy and spleen-renal anastomosis without waiting for the first hemorrhage to occur. Admittedly a portocaval anastomosis does effect a greater reduction in portal pressure than does a spleen-renal anastomosis, but in some cases, at least, the congestion of the spleen is not relieved rapidly after a portocaval anastomosis, and the harmful effects of hypersplenism are not promptly eradicated. In selected cases, the removal of the spleen and the performance of a spleen-renal anastomosis may be the operation of choice.

Primary biliary cirrhosis illustrates some additional clinical aspects of intrahepatic obstructive jaundice. It seems important to emphasize that icterus may not necessarily be the first manifestation of the disorder, though the diagnosis is seldom considered before jaundice does appear. In this disease the degree of elevation of serum bilirubin level does not necessarily parallel the degree of parenchymal cell damage as it usually does in other forms of cirrhosis. In such patients, a coexisting hemolytic process related to congestive splenomegaly may greatly exaggerate the degree of icterus.

Summary

The clinical features of jaundice due to intrahepatic obstruction closely simulate those of extrahepatic biliary obstruction. In most instances a correct diagnosis can be made by analyzing the data obtained by clinical, laboratory, x-ray, and histological studies. In some instances operative cholangiography may be required if, after four to six weeks of medical treatment and study, the distinction cannot be made.

Primary intrahepatic cholestasis represents one form of jaundice resulting from intrahepatic obstruction. It is usually a manifestation of a drug sensitivity phenomenon of the type seen in patients who develop reactions to arsenical drugs or chlorpromazine. The intrahepatic obstruction to bile flow is usually self-limited. In rare instances, jaundice may be protracted.

Jaundice due primarily to intrahepatic obstruction (cholestasis) rather than to hepatocellular damage is occasionally seen in patients with viral hepatitis. An experienced pathologist can usually make the correct diagnosis on the basis of a needle biopsy of the liver.

Jaundice due to intrahepatic obstruction is a prominent clinical feature of primary biliary cirrhosis. The rate of bilirubin production (i. e., rate of red blood cell destruction) must be considered in assessing the clinical significance of the degree of icterus at any given time in the course of this progressive disease.

MECHANISMS OF BILE SECRETION

Ralph W. Brauer, Ph.D., San Francisco

The formation of bile in the liver is a complicated process. One group (A) of substances appears in bile in the same concentrations as in blood; this includes glucose and the chlorides of sodium and potassium. A second group (B) appears in bile concentrated as much as hundredfold; this group includes the bile salts, bile pigments, and certain test substances like sulfobromophthalein. A third group (C) is retained in the blood and appears in the bile only in very low concentrations, if at all. Groups A and B are controlled independently of each other, and substances of group B are transferred from blood to bile by an active secretory process. The transfer of sulfobromophthalein involves some active secretion, some storage, and some chemical conversion with other phenomena in addition. Since better understanding of these processes is essential to the interpretation of functional tests and the planning of treatment, further fundamental research is needed.

Bile occupies a peculiar position among secretions: It appears to be somewhere intermediate, from the point of view of its origin, between urine—the result of a sequence of filtration, reabsorption, and secretion—and milk, saliva, or other secretions which spring fully formed from the body of the cells of many typical glands. Understanding of the mechanisms of bile formation has lagged, in spite of a large volume of experimental observations, largely because the pattern of a functional anatomy of the hepatic secretory apparatus has not been established to date. Yet, I believe that enough data have accrued in recent years to justify an attempt at formulating such a picture. This communication will present the results of such an attempted synthesis together with a brief synopsis of the type of experimental material on which my model is based.

Bile is a highly complex composite secretion of widely varying composition. Sometimes this truism if lost sight of, especially in discussions of histopathological material where long-standing usage sanctions the use of the term "bile" to describe the visualization of stainable bile salts or of bile pigments. Many of the difficulties in understanding the pathophysiology of cholestasis can be traced back to this semantic difficulty.

For present purposes, the major bile constituents can be divided into three classes on the basis of the degree of concentration they experience in passage from blood to bile. Class A includes Na^+, K^+, Cl^-, and glucose, with a bile-blood concentration ratio of nearly 1.0; class B includes taurocholates, glycocholates, other bile salts, dehydrocholates, bilirubin diglucuronide, other bile pigments, sulfobromophthalein, fluorescein, rose bengal, and possibly creatinine, with a concentration ratio of 1:10 to 1:1,000; and class C includes alkaline phosphatase, inulin, sucrose, phosphates, and possibly cholesterol, phospholipids, and mucoproteins (plasma proteins, with the exception of alkaline phosphatase, appear not to be represented in the bile), with a concentration ratio of less than 1.0.

This classification can be traced back at least to the experiments of Höber and his school.[1] For the present discussion only classes A and B are relevant. They account for the water and about 95% of the dry matter of bile. Class C poses a series of intriguing but as yet largely unsolved questions and will be left out of the following discussion.

Class A Substances

Class A substances, almost by definition, are transferred to bile in a group, and the rate of their transfer bears no necessary relation to the rate of class B compound secretion.[2] The table lists a few examples in which changes in bile flow rate or composition occur in the absence of corresponding blood composition changes, suggesting that the mechanisms of class A and of class B secretion should be considered as independent of each other in any analysis of bile secretion.

The fact that class A substances as a group appear in bile in concentrations closely reflecting those of plasma has suggested to some that a filtration reabsorption process is the basis of bile volume control. This, however, is incompatible with the experimental facts.

Thus, filtration can be ruled out because bile flow continues up to limiting pressures which, in the isolated rat liver, are always greater than blood pressures.[3] If, furthermore, one takes into account the effective colloid osmotic pressure of the plasma proteins (all but one or two minor ones of which are absent from bile), a pressure differential of such magnitude results that any filtration process can be ruled out a priori. Even a second order con-

tribution of blood pressures to bile flow rate can be ruled out, since bile flow rates are independent of blood flow or blood pressure whenever the oxygen supply to the tissue is not the limiting factor. This condition can be satisfied at fairly high rates of perfusion at body temperature[3] or over an extreme range of perfusion rates (from 0.3 to 3.0 cc. per gram of liver per minute) either at reduced temperature (30 C) or at elevated oxygen partial pressures (4 atm.).[4]

Active reabsorption also can be eliminated as a factor in bile volume regulation. Under constant blood flow conditions, cooling of the liver results in a sharp fall of bile flow rate—not a rise, as would be predicted from any mechanism dominated by reabsorption. In the rat liver, a 10 C reduction of perfusion temperature reduces bile flow rate by a factor of four between 38 and 18 C.[5] Likewise, ether anesthesia results in a reversible fall of bile flow rate. Thus, it would appear that, in essence, bile formation involves the active transfer of water and possibly of other class A substances from blood to bile.

Examples of Independent Variability of Secretion into Bile of Class A and Class B Components

	Condition	BSP Secretion Rate	Taurocholate Concentration	BSP Concentration Maximum	Bile Flow Rate
Dog (BSP infusion)	Breathing actively	1.30 mg./min.	...	...	98 microliters/min.
	Diffusion respiration (2.5 atm. O_2)	1.07 mg./min.	...	...	38 microliters/min.
Rat (isolated liver)	During 1st hr. of perfusion	...	2.3 mg./cc.	...	1.2×10^{-2} cc./min.
	During 3rd hr. of perfusion	...	0.25 mg./cc.	...	1.0×10^{-2} cc./min.
Rat (isolated liver; 3 mg. of BSP injected)	38 C	...	...	94 mg./cc.	1.5×10^{-2} cc./min.
	30 C	...	...	97 mg./cc.	0.42×10^{-2} cc./min.
Rat (isolated liver)	During steady state	95 mcg./min.	...	...	2.2 cc./min.
	In spontaneous failure	85 mcg./min.	...	...	0.50×10^{-2} cc./min.
Dog (bile fistula)	Continuous BSP (or penicillin) infusion at various rates	BSP (or penicillin) "clearance" rate decreasing sharply with increasing plasma BSP concentration			
	Sodium or lithium chloride by continuous infusion at various rates	Sodium or lithium "clearance" independent of plasma sodium or lithium concentrations			

Further light on blood-bile relations is shed by the study of such other class A components as the monovalent ions Na^+, K^+, and Cl^-. The concentrations of all of these in bile rigorously parallel their concentrations in blood plasma regardless of how much deviation from normal blood levels is seen. In rat bile, potassium concentrations exceed plasma potassium concentrations by about 15%, while sodium and chloride concentrations are very nearly equal in the two phases.[6] This equality of plasma and bile electrolyte concentrations—and osmotic pressures—is preserved even when plasma osmolarity is doubled by the addition of sodium chloride. Bile flow rate, however, is drastically reduced by such a procedure, indicating once again that a cellular phase rather than extracellular equilibrium governs bile flow rate. The location of this cellular phase is suggested in this case by the appearance of watery vacuolation in the hepatic polygonal cells.[7]

The dominant role of the hepatic cells in bile secretion is further confirmed by the observation that in many forms of toxic hepatitis, where bile suppression is among the earliest physiological manifestations, early histopathological changes are confined to these hepatic cells.[8] Thus, transfer of water to bile involves an active, energy-consuming process, is likely to be located at the level of the hepatic cells, and consequently would appear to involve of necessity the transfer of water into the bile capillaries enmeshing these cells.

Once in the biliary tree, bile is not completely isolated from the blood stream. Thus, a net transfer of fluid out of the biliary tree could be demonstrated at elevated bile pressures.[3] The rate of such backflow is dependent on bile pressure: it appears to be nil or very slow, relative to bile secretion at pressures up to about 12 cm. H_2O, and increases very rapidly with further increases in bile pressure until backflow balances secretion rate. This point is the one commonly determined in measurement of so-called bile secretion pressures. Bile composition appears to be independent of bile pressures below 10 or 12 cm. and varies at higher pressures in a manner suggesting interference with the secretory apparatus rather than concentration of bile by selective back filtration.[1] When hepatic venous pressures are elevated at constant portal pressure, it has been found in the isolated rat liver that limiting bile secretion pressures are not similarly raised but either remain constant or decrease slightly. This finding suggests that leakage of bile from the biliary tree under these conditions occurs not at the level of the sinusoidal bed but, rather, hemodynamically close to the entry of the portal blood into the liver, i. e., at the level of the portal areas or even further upstream.

Exchange of electrolytes can occur between bile in passage through the biliary tree and blood plasma. This follows in particular from studies of bile potassium: after radioactive potassium (K^{42}) injection into the blood stream, the specific activity of the large hepatic intracellular potassium pool rises somewhat gradually while bile potassium specific activity has reached the values prevailing in plasma within about one minute.[4] Bile potassium thus is derived from blood and not from the cellular phase of the hepatic parenchyma. The rate of K^{42} appearance, furthermore, suggests that this ion entered the biliary tree pretty well downstream rather than in the canalicular headwaters. Similar results, though less sensitive because of the small sizes of intracellular stores, have been obtained for Na^+ and Cl^-. Together with the above data on the origin of the biliary fluid phase, these data, then, provide the basis for the conclusion suggested above that bile secreted by the hepatic cells in passage down the biliary tree is afforded an opportunity to reach electrolyte equilibrium with the blood plasma. It is tempting to assign this process to the small bile ducts and ductules with their investing vascular plexuses.[9]

Class B Substances

In contrast with class A bile components, those of class B appear in bile in such concentrations that there can be no doubt about the fact that an active secretory process of some kind must be involved in the transfer from blood to bile. Class B compounds share a number of chemical characteristics: they are usually organic carboxylic acids or their salts of molecular weights of the order of 300 or greater, and they share a marked tendency to form complexes with plasma proteins, particularly with plasma albumin. With respect to secretion into bile, also, there are many similarities between these substances, although quantitative differences may exist between them with respect to the degree to which particular properties are displayed. Sulfobromophthalein sodium, an exogenous dye, has had perhaps more study than any other compound from the point of view of its fate in relation to bile secretion. Since, wherever they have been checked, conclusions derived from the study of sulfobromophthalein secretion correspond with observations for other class B compounds, attention here will be focused on this substance as a prototype of the entire class.

Sulfobromophthalein is secreted into bile at concentrations that always far exceed those in the blood stream. Characteristically, however, there is a limiting rate of dye secretion beyond which increasing the dose or the infusion rate of sulfobromophthalein no longer affects the secretion rate; the mechanism involved, whatever its nature, appears to be saturated.

Similar saturation phenomena have been seen for sodium dehydrocholate, bilirubin, and fluorescein[7] and would appear to be characteristic of the biliary secretion of class B compounds in general. Related to this property may well be that of competition for uptake and excretion by the liver, a phenomenon well recognized for the pair dehydrocholate and sulfobromophthalein[10] and recently described also for other pairs, such as bilirubin and sulfobromophthalein and bilirubin and bile salts.[7] A similar mechanism may underlie the inhibition of sulfobromophthalein uptake in the presence of probenecid (Benemid) and of certain shellack suspensions.[7] There is a suggestion in these data that uptake—that is, blood to secretory cell transfer—rather than secretion into bile is involved in these mutual inhibitions.

The path of class B compounds from blood to bile has been explored visually, by tracer methods, and physiologically. By visual observation of fluorescein secretion, Hanzon has demonstrated a sequence of uptake into parenchymal cells, secretion into bile canaliculi, and transport down the biliary tree for this dye.[7] Tracer studies involving sulfobromophthalein labeled with radioactive sulfur (S^{35}) have confirmed and expanded this picture. In the first place, they have proved that blood to bile transport of sulfobromophthalein must involve a cellular phase. Bile in several species does not contain sulfobromophthalein as such but, rather, a series of sulfobromophthalein derivatives together with traces of sulfobromophthalein only.[11] The conversion does not take place in the blood stream, for blood contains mere traces of these sulfobromophthalein derivatives over most of the course of sulfobromophthalein excretion, and the hepatic parenchyma is very active in effecting the conversion. The end product of sulfobromophthalein metabolism in the rat is a phthalein dye, provisionally designated as sulfobromophthalein II, which is secreted without further conversion into bile. The fact that blood-to-bile concentration ratios for this dye, too, are always considerably below 1:1, ranging around 1:10 to 1:50 during continuous infusions in the isolated rat liver, conclusively proves that chemical conversion is not essential to uphill secretion of class B compounds into bile.

Transfer of sulfobromophthalein from blood to bile is not a simple a-to-b process. Even at subsaturation doses, as much as half of the dye entering the cells is stored away.[12] The site of storage appears to be the hepatic cell, both from analogy with fluorescein and on the basis of radioautographic studies. The stored dye is eventually available for excretion into bile. However, maintenance of high secretion rates depends on continued delivery of sulfobromophthalein or of its derivatives to the liver via the blood stream: transferring an isolated liver loaded with sulfobromophthalein or sulfobromophthalein II from the dye-containing circulation to a fresh, sulfobromophthalein-free circulation results in a rapid falling off of dye concentrations in the bile. This behavior is in line with the mode of action of the inhibitors of sulfobromophthalein handling mentioned above.

If S^{35}-labeled sulfobromophthalein II is used in the first and ordinary sulfobromophthalein in the second circulations of such perfusion experiments, the falling off in the rate of excretion of stored up S^{35}-labeled dye after the transfer is virtually the same as though no dye were present in the second system, suggesting that stored sulfobromophthalein and freshly delivered sulfobromophthalein are secreted independently at these dosage levels. That storage and secretion of sulfobromophthalein are somewhat independent processes can also be observed in toxic liver injury; here, secretion of sulfobromophthalein is severely impaired,[12a] while storage remains effective as shown both by direct analysis[12a] and, for the damaged cells, by histological methods.[13] Similarly, in the chick embryo hepatic storage and chemical conversion are demonstrable several days before biliary sulfobromophthalein excretion.[14]

Thus, a complex picture of sulfobromophthalein handling in the liver is gradually emerging, incorporating a storage phase, possible chemical conversion, and secretion as its elements. Anatomic counterparts to these at present can only be derived by analogy with the results of direct observation of fluorescein. As before for water transfer, the parenchymal cell appears to emerge as the central secretory element for class B substances. Rigorous proof of this, however, remains to be furnished.

If the hepatic cell is the primary agent of sulfobromophthalein secretion, the dye thus secreted is delivered into the bile canaliculi which invest the hepatic cells. This conclusion once again is in agreement with Hanzon's in vivo microscopic observations.[7] In passage down the biliary tree, the sulfobromophthalein-laden bile must traverse the zone where plasma-bile equilibration occurs with respect to sodium, potassium, and chloride. In the case of class B substances, however, the rate of exchange must be far slower, since otherwise the very large concentration gradients between blood and bile could not be maintained. Possible evidence for the existence of such exchange may be found in the gradual appearance in plasma of biliary sulfobromophthalein derivatives after sulfobromophthalein injection. In bile stasis, far greater back-transfer is seen both in the blood and in liver lymph,[7] together with recycling which results in accumulation of the end product of sulfobromophthalein metabolism—sulfobromophthalein II in the rat—in the blood and liver; this, however, could represent bulk regurgitation rather than diffusion exchange. The difference in rate of exchange between sulfobromophthalein and similar compounds on the one hand and of K^+ or Cl^- on the other can be reproduced in simple collodion bag dialysis experiments, where the rate constant for sulfobromophthalein exchange is less than one-tenth as fast as that for Cl^- or K^+ exchange at concentrations comparable to those in plasma and bile. Thus, when in a typical experiment sulfobromophthalein concentration inside the bag had decreased from 100% to 80% of the initial value of Cl^- exchange was 92% complete.

Hypothermia affects sulfobromophthalein secretion rates to about the same extent as bile flow.[4] Elevated bile pressures fail to affect bile sulfobromophthalein concentrations until levels are reached where bile backflow assumes important proportions; in that region bile sulfobromophthalein levels may decrease below normal for a given dose. Both these lines of observation confirm the view that selective reabsorption is not a factor in establishing sulfobromophthalein concentrations in bile.

I would like to mention two alternative points of view on sulfobromophthalein handling in the liver. Kupffer's cells were once considered involved in this process on the basis of the effect of India ink on sulfobromophthalein clearance.[15] More recent work has resolved this experiment by the demonstration that something in the suspension medium (the shellack, on most recent evidence) rather than the so-called RE blocking colloid is at the base of the effect and that loading of Kupffer's cells with inert colloid fails to modify sulfobromophthalein handling in the liver.[16]

Again, a most interesting point of view was proposed on the basis of the demonstration of an extensive peribiliary vascular plexus supplied by the hepatic artery; it was proposed that this was an expression of a major functional role of the bile ducts and that this role was the secretion of important bile components, including sulfobromophthalein.[17] As far as the latter assertion is concerned, direct check with use of simultaneous injection of sulfobromophthalein into the portal vein and of S^{35}-labeled sulfobromophthalein into the hepatic artery of dogs has shown either that there are no route-dependent differences in secretion of dye or that the dye introduced into the portal vein is actually secreted preferentially. Thus, the bile ducts do not appear to play a predominant active role in sulfobromophthalein secretion.[18] The peribiliary plexus would, however, appear to be an excellent anatomic device for effecting the exchange between blood and bile constituents described in preceding sections of this paper.

Comment

The following concept represents a useful working hypothesis of the mechanism of bile secretion: Bile flow is initiated by the secretory activity of the hepatic cells. Since, at present, no other single bile component appears to be linked with this process, it seems useful to consider this process as water secretion. Substances of class B are transferred from blood to bile by the same hepatic cells, forming a primary bile in the bile canaliculi.

Primary bile, in passage down the biliary tree, comes into restricted contact with blood plasma. This results in equilibration of Na^+, K^+, and certain other ions and may result in a limited loss from bile of class B components. The difference in exchange rates seems to be largely due to differences in diffusion rates in solution and to differences in ionic radii in relation to the effective pore sizes of the membranes separating blood and bile.

Bulk transfer of bile from the biliary tree to the blood stream can occur when bile pressures are raised. Under such conditions, as well as in the normal liver, selective retention in bile of specific components appears to be of minor importance in determining bile concentration. Anatomically, the peribiliary vascular plexus may represent the area of blood-bile exchange and the juxtasinusoidal extensions of the bile canaliculi,[19] as well as the ductular region,[7] appear likely sites for bulk backflow.

Conclusions

The physiological anatomy of bile secretion, as has been proposed, must be subjected to much further experimental work along such promising lines as the analysis of liver lymph composition, the effects of intermittent or of relative bile stasis, and the ontogeny of bile secretion and its relation to the biochemical and morphological development of the liver. At the same time, I feel that enough background is available to justify preliminary turning of attention to the basic mechanisms which convert the energy provided by biochemical reactions to the physical work of bile secretion. A beginning in this direction has been made in oxygen tension—bile flow studies, in the exploration of enzyme inhibitor effects on bile flow and of the biochemical effects of certain hepatotoxins, in attempts to correlate nutritional studies and bile secretion, and, in particular, in the exploration of the intriguing variety of effects of the several bile flow–stimulating or choleretic agents. This, however, is another tale which, I hope, can be considered in a future discussion.

CLINICAL NOTES

PERSISTENT SUBARACHNOID-PLEURAL SPACE FISTULA

REPORT OF A CASE

Frank J. Milloy, M.D., Noble O. Correll, M.D.
and
Hiram T. Langston, M.D., Chicago

A fistulous connection between the subarachnoid space of the spinal canal and the pleural space is evidently a rare pathological entity. We have been unable to find a previous account of this condition in the literature. We feel, therefore, that the following case report should be of interest.

A 19-year-old paraplegic man was admitted to the Chicago State Tuberculosis Sanitarium on Oct. 31, 1955, because of a right pleural effusion. The history revealed that he had had no significant illness until 1952, when he received a thoracoabdominal gunshot wound. This wound made an emergency exploratory laparotomy necessary and also was the cause of his present paraplegia. Since the onset of paraplegia he had developed chronic urinary tract infection and decubitus ulcers.

Examination revealed paraplegia of the lower extremities and skin anesthesia from the level of the 10th thoracic segment down. There was a surgical scar on the upper part of the abdomen and a bullet could be palpated in the subcutaneous tissues of the back, near the midline, at about the level of the sixth thoracic vertebra. Breath sounds were impaired in the right lung base.

On Oct. 2, 1955, the patient had developed the pleural effusion while in another hospital. This occurred six weeks after intraspinal alcohol injection, which was given in an attempt to convert the paraplegia from the spastic to the flaccid type. At thoracentesis, 1,800 cc. of clear fluid was obtained. The pleural fluid was negative bacteriologically. The Mantoux test (with purified protein derivative) gave a positive finding in second strength.

Even though there was no bacteriological confirmation of a tuberculous cause, the patient was placed on therapy with streptomycin, aminosalycilic acid, and isoniazid. After eight months of treatment with these drugs, the patient continued to form fluid at a rate requiring removal of 1,000 to 1,500 cc. every two or three weeks. All bacteriological studies of this fluid, including guinea pig inoculations, continued to show negative results. The specific gravity of the fluid was 1.010, the cell count varied from 1 to 3 per cubic millimeter, and the total protein content varied from 1.25 to 1.83 Gm.%. Total cholesterol level was 22 mg.%.

At thoracotomy, 3,500 cc. of straw-colored fluid was removed from the right side of the chest. The pleura was completely normal in appearance except for adhesions along the bullet tract. This appearance was baffling until a minute, dimple-like defect was found in the pleura on the lateral surface of the vertebral column which was exuding small amounts of clear fluid. This defect was probed and found to be a fistulous tract which passed toward the posterior portion of the seventh thoracic vertebra. This tract was unroofed to the point of its termination in the spinal canal, where a small perforation in the dura was discovered. The dura was opened sufficiently to inspect the cord and to make sure no foreign body was present. The dura was then closed with fine silk, and flaps of intercostal musculature and pleura were brought across the site of the fistula to help obliterate it. The parietal pleura was then stripped in the gutter and lateral chest wall to insure subsequent pleural symphysis.

Postoperatively, the patient complained of headaches for about six weeks. This symptom was relieved by lumbar puncture on one occasion. These headaches gradually subsided, and the patient was returned to his original hospital. He has had no recurrence or subsequent complications in a follow-up period of one and one-half years.

Comment

We have presented the case of a paraplegic youth who developed a pleural effusion three years after a gunshot wound which caused his paraplegia. The offending bullet had apparently traversed the right side of the chest, vertebral column, and spinal canal. The pleural effusion developed six weeks after an intraspinal alcohol injection. It was at first presumed to have a tuberculous origin, but after an adequate period of antituberculosis therapy the effusion did not subside and exploratory thoracotomy was performed. This revealed the presence of a fistula between the pleural and subarachnoid spaces.

We are unable to account for the three-year interval between the gunshot wound which produced the fistulous tract and the onset of the effusion. Although the alcohol injection seems to be the only significant event associated with the appearance of the effusion, a causal relationship is not clear.

1919 W. Taylor St. (12) (Dr. Langston).

BLOOD DYSCRASIAS ASSOCIATED WITH TOLBUTAMIDE THERAPY

Franz Jost, M.D., New York

During the three years of its use, tolbutamide has established a remarkable record for safety. Side-reactions have been relatively few, consisting of mild gastrointestinal disturbances, skin eruptions, and mild granulocytopenias.[1] These reactions are generally not serious and disappear either after discontinuation of use of the drug or in spite of its continued administration. To date, no serious untoward reactions have been reported. Reactions, however, do occur. It should not be surprising, therefore, if an occasional case should assume grave proportions. With this thought in mind, a case is reported in which serious depression of the bone marrow was observed during the course of treatment with tolbutamide.

Report of a Case

A 69-year-old man was admitted to St. Vincent's Hospital on Aug. 7, 1956, with the chief complaint of weakness and collapse. The history revealed that in 1940 he was hospitalized for rectal abscess and in 1942 for cellulitis of the legs. In 1950, he was found to be hypertensive and suffering from obliterative arteriosclerosis and varicose veins with intermittent claudication. In 1951, a saphenous vein ligation was done; three months later, a sympathectomy on the left side was performed. In 1952, sympathectomy was done on the right. In 1954, he began to suffer from angina pectoris.

Diabetes was detected in 1939 when he was hospitalized for treatment of a rectal fistula. There were no symptoms of diabetes. The diabetes was treated with diet alone for the first year; thereafter, 30 to 35 units of protamine zinc insulin was taken daily. Control of diabetes had been poor due to lack of cooperation. Two years prior to the present illness, the patient changed his attitude and paid close attention to his diet and insulin dosage. Since then, control has been excellent, as manifested by almost normal blood sugar levels, minimal glycosuria, and freedom from hypoglycemic reactions. The weight remained stable. Several blood cell counts during this period were either normal or showed mild degrees of anemia attributed to rectal bleeding from hemorrhoids.

On May 29, 1956, the fasting blood sugar level was 132 mg.%; the urine showed a trace of albumin but no sugar or acetone. His weight was 164 lb. (74.4 kg.). The patient was well and asymptomatic. Therapy with protamine zinc insulin was discontinued.

On June 5, 1956, the fasting blood sugar level was 211 mg.%. A mild postprandial glycosuria was recorded, but acetone was not present. His weight was 159 lb. (72.1 kg.). The patient felt well and was asymptomatic. No insulin was recommended.

History of Present Illness.—On June 19, 1956, the fasting blood sugar level was 279 mg.%; a moderate glycosuria was noted throughout the day but no ketonuria. The patient's weight was 157 lb. (71.2 kg.). He had no symptoms and no complaints. A blood cell count was ordered, and the patient was placed on tolbutamide therapy, 1 Gm. before breakfast and supper. No report on the blood cell count was received.

On June 26, 1956, the fasting blood sugar level was 127 mg.%; there was mild postprandial glycosuria. His weight was 156 lb. (70.8 kg.). There were no signs of hypoglycemia, no symptoms, and no complaints. The evening dose of tolbutamide was reduced to 0.5 Gm.

On July 10, 1956, urine findings were unchanged. The fasting blood sugar level was 162 mg.%. The patient looked and felt well but complained of mild exertional angina in the morning. Tolbutamide dosage was increased to 1 Gm. given twice daily.

During the following weeks, the patient did not return for weekly check-ups as was advised. When he appeared again on Aug. 7, 1956, he was pale. He reported that for three weeks he had felt weak and had collapsed several times. He blamed the tolbutamide for his symptoms and stopped taking it, but he did not resume insulin therapy. When he did not notice any improvement, he returned to the clinic.

The urine showed glycosuria but no ketonuria. He was admitted to the hospital. Physical examination showed his weight to be 154 lb. (69.9 kg.), temperature 98 F (36.6 C), pulse 80 per minute and irregular, blood pressure 140/76 mm. Hg, and respiration rate 20 per minute. The lungs showed crepitant rales at both bases. The heart was slightly enlarged, and a faint systolic murmur was heard over the apex. There were operative scars on the lower extremities. The feet were cool, and the pedal pulses were not palpable. The tendon reflexes were absent in the lower extremities. Chest x-ray showed cardiac enlargement, pulmonary congestion, and a small pleural effusion on the right side. The electrocardiogram showed atrial fibrillation with a left ventricular strain pattern. The blood cell count was as follows: hematocrit value, 20%; hemoglobin level, 5.8 Gm.%; red blood cell count, 2,300,000 per cubic millimeter; and white blood cell count, 2,200 per cubic millimeter, with reticulocytes 0.6%, polymorphonuclears 43%, lymphocytes 48%, monocytes 4%, and platelets 80,000 per cubic millimeter. Bone marrow revealed sparsely cellular marrow with relative hypoplasia of the myeloid and relative hyperplasia of the erythroid series.

The patient was given blood transfusions. The diabetes was promptly controlled with diet and insulin and the cardiac decompensation corrected with digoxin and diuretics. Attempts to improve the blood dyscrasia with vitamin B_{12}, liver extract, iron, and steroids were unsuccessful. The patient was kept comfortable by repeated transfusions. He was discharged on Aug. 29, 1956, and advised to return at stated intervals for reevaluation. Repeated bone marrow examinations were done during his stay in the hospital but revealed no significant change.

The patient was readmitted to the hospital on Sept. 11, 1956. Except for the absence of congestive failure the physical findings were unchanged. The vital signs were normal. The laboratory data revealed blood urea nitrogen level, 20 mg.%; creatinine level, 2.5 mg.%; hemoglobin level, 6.4 Gm.%; red blood cell count, 2,400,000 per cubic millimeter; and white blood cell count, 2,600 per cubic millimeter, with polymorphonuclears 40%, eosinophils 2%, monocytes 1%, lymphocytes 57%, and platelets 61,000 per cubic millimeter. Repeated blood cell counts at weekly intervals revealed no significant changes.

The patient was given blood transfusions. A second trial with the above-mentioned hematinics proved equally unsuccessful. The patient remained fairly comfortable until Oct. 9, 1956, when he experienced a moderate sustained fever and signs of pneumonia at both lung bases. Tetracycline (Achromycin) was given, and the temperature returned to normal after four days. On Oct. 16, 1956, the patient, while sitting quietly in a chair, suddenly fell over and died.

Autopsy was performed on Oct. 18, 1956, by Dr. Julia Miyares. A brief summary of the findings is as follows: arteriosclerotic heart disease with coronary artery sclerosis; segmental narrowing and subintimal hemorrhage of the left anterior descending coronary artery; and subendocardial and subepicardial petechiosis of the myocardium. The lungs showed confluent lobular pneumonia, involving the right

---

From St. Vincent's Hospital.

middle and left lower lobe with a small caseous tubercular focus in right upper lobe. The pancreas was the site of mild hemorrhagic peripancreatitis. The bone marrow revealed marked hypoplasia of the granulocytic, megakaryocytic, and erythroid series. The features were those of severe hypoplasia.

Comment

It may well be said that conclusive proof for causal connection between tolbutamide therapy and the blood dyscrasia has not been established since there is no record of a blood cell count immediately preceding use of the drug. Against this contention, however, are the following facts: For quite some time before and for at least three weeks after the use of tolbutamide, the patient felt well, looked his usual self, and had no complaints except that of occasional mild angina, which he had been having for over two years. Search of his records for over four months prior to his anemia failed to reveal any suggestive complaints or use of other medication. The patient himself denied taking any medicine, nor could any history be elicited that indicated exposure to other toxic agents. The patient's history and the blood findings in August, 1956, are compatible with the suggestion that the onset of the dyscrasia occurred shortly after the beginning of the use of tolbutamide. Certainly, the consideration of the possibility of a causal connection between the drug and blood findings appears justified.

Summary and Conclusions

Severe, protracted, and probably lethal aplastic anemia occurred in a patient taking tolbutamide. This should in no way discourage the use of this effective and generally remarkably safe drug. It should, however, remind the physician of the possibility that mild and inconsequential reactions may occasionally assume grave proportions and alert him to the necessity of detecting them by frequent blood cell counts early in the course of treatment.

LEG ULCER IN RHEUMATOID ARTHRITIS

Louis W. Granirer, M.D., Jamaica, N. Y.

Rheumatoid arthritis has many visceral manifestations which serve to emphasize the systemic nature of the disease. Lesions have been reported in the nerves, muscles, heart, brain, eye, bones, gastrointestinal tract, pleura, lungs, and larynx.[1] This paper presents the clinical and histological findings in a patient with a leg ulcer in rheumatoid artritis.

Report of a Case

A man, aged 52, was admitted to the Arthritis Clinic on Feb. 2, 1957, with a history of rheumatoid arthritis since 1946. He was thin and pale. The hip joints, right knee, ankles, and right elbow and wrists were swollen and tender. The adjacent muscles were conspicuously wasted. The proximal interphalangeal joints showed characteristic "spindling" deformities, and the fingers were deviated to the ulnar side. There was a poor response to therapy with gold salts, prednisone, prednisolone, and triamcinolone in large doses. Facial roundness was evident, and he had a palpable spleen. The blood hemoglobin level was 11 Gm. per 100 cc.; the white blood cell count was 4,200 per cubic millimeter, with 65% polymorphonuclear neutrophil leukocytes; and the erythrocyte sedimentation rate (Westergren) was 55 mm. in the first hour. The latex fixation test gave a positive result. The serum uric acid level was 2.5 mg. per 100 cc. The L. E. cell test and Wassermann test showed negative results. The temperature was 99 F (37.2 C) and blood pressure, 130/90 mm. Hg. The heart showed a moderate degree of left ventricular hypertrophy. Subcutaneous nodes (3 cm. in diameter) were found over both olecranon processes.

In April, 1957, he suddenly developed a painful ulcer in the posterior lower third of the right leg. It measured 4 by 5 cm. and was 0.5 cm. in depth (fig. 1). The ulcer was similar to those previously reported.[2] The margins were sharply demarcated with a typical punched-out appearance. There was little discharge, with minimal inflammatory reaction in the surrounding tissue. A greyish exudate was evident at the base of the ulcer. The pain was very distressing. My interest was intensified by the fact that this lesion did not respond to routine and accepted measures of therapy. There was no evidence of varicosities, no deep or superficial venous thrombosis, no diabetes mellitus, no evidence of infection, and no edema. Repeated cultures showed no pathogenic organisms. Complete bed rest with elevation of the foot of the bed had no effect. Prolonged local and general antibiotic therapy, steroids, gold salts, phenylbutazone, trypsin (Parenzyme), streptokinase-streptodornase (Varidase), ultraviolet rays, sulfonamides, and flexible adhesive bandage were unsuccessful.

A specimen of tissue from the ulcerated area showed three distinct features: a zone of necrosis and fibrinoid alteration; an intermediate zone characterized by palisading of histiocytes and young fibroblasts with infiltration of small round cells; and an outer zone of fibrous tissue with numerous blood vessels (fig. 2). These histological characteristics are in accord with the typical lesion of the rheumatoid nodule described by Klinge[3] in 1933 and are considered to be pathognomonic.

With large doses of methylprednisolone, this patient experienced a dramatic relief from pain and stiffness as well as a decrease in all the objective signs of joint disease. The subcutaneous nodules rapidly lost their tenderness and diminished in size. Withdrawal of the drug was followed by a rapid increase in the size and tenderness of the subcutaneous nodules. The leg ulcer, however, demonstrated no change during steroid therapy. This feature has been previously recorded in similar patients and was of considerable interest.[2]

From the Arthritis Clinic and Department of Medicine, Queens General Hospital.

Comment

Although rheumatoid disease has previously been described in practically all of the viscera, the precise site and the histological appearance of the leg ulcer has not been clearly defined. In a recent report of 200 leg ulcers, 150 were classified as varicose, 30 as post-thrombotic, and 20 as miscellaneous.[4]

Edema was considered to be the final cause in all three groups. The edema was due to the failure of weakened or poorly used calf muscles to maintain an adequate venous return (e. g., hemiplegia, rheumatoid arthritis, arthritis of hip and knee).

The leg ulcer reported here was very painful and was not relieved by rest. It presented a typical punched-out appearance with very little drainage. It occurred in the lower third on the posterior aspect of the leg and did not respond to conventional therapy. (The original hypothesis of edema as the cause did not provide a satisfactory explanation.)

Not all patients with rheumatoid arthritis develop leg ulcers. It is plausible that trauma may play an important etiological role. Two ulcers of this type have been observed to heal with no specific type of therapy.

Whether the connective tissue is a prime reactor in rheumatoid disease or is involved secondarily, Gross [5] believes that the crippling deformities and much of the functional impairment result from failure of the newly forming connective tissue to reproduce the normal structures. Although this healing phase may be nonspecific, it is a major feature of the course and ultimate consequence of this disease. In his opinion, there is little evidence as yet that collagen is involved in any way other than as an innocent bystander or in the healing of accompanying injury. Fibrinoid has long been considered the hallmark of connective tissue diseases and yet may be nothing but the end-result of a relatively nonspecific process. It may be recalled that the cause and cure of scurvy, a connective tissue disease, are known, but the biochemical functions of vitamin C are still unknown.[5]

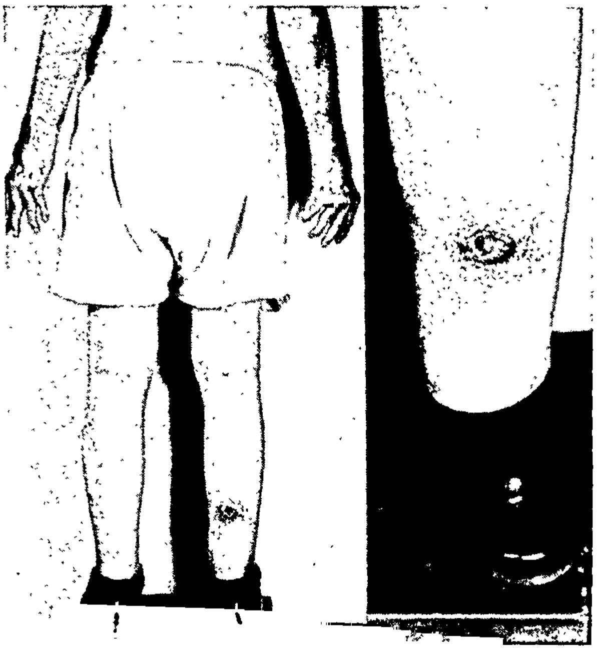

Fig. 1.—Leg ulcer in patient with rheumatoid arthritis.

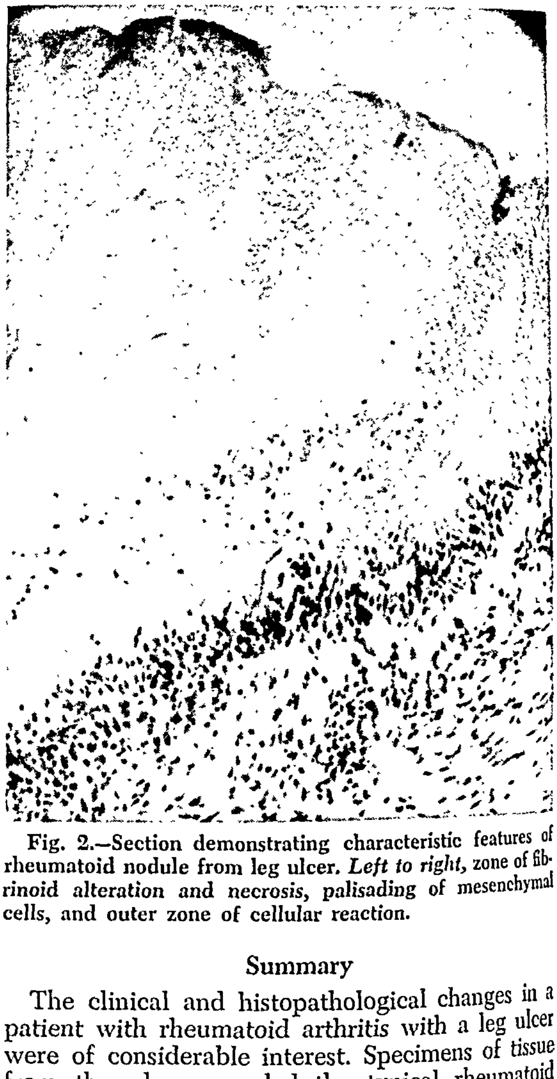

Fig. 2.—Section demonstrating characteristic features of rheumatoid nodule from leg ulcer. *Left to right,* zone of fibrinoid alteration and necrosis, palisading of mesenchymal cells, and outer zone of cellular reaction.

Summary

The clinical and histopathological changes in a patient with rheumatoid arthritis with a leg ulcer were of considerable interest. Specimens of tissue from the ulcer revealed the typical rheumatoid nodule. The lesion did not disappear with any routine therapy, including that with large doses of corticosteroids. The clinical course in a case previously observed followed a similar pattern.

SPECIAL ARTICLE

HISTORY OF THE SECTION ON OBSTETRICS AND GYNECOLOGY OF THE AMERICAN MEDICAL ASSOCIATION

Woodard D. Beacham, M.D., New Orleans

I am grateful for the honor of your addition of my name to the roster of obstetricians and gynecologists who have occupied the chairmanship of this section, and I appreciate the opportunity of presiding at its 94th meeting. I was tempted to prepare a Chairman's address concerning the misuse of words in our discipline. For example, when one really means "nullipara" he should not say "primipara." However, consideration of philosophical subjects and reports of progress in our specialty required me to seek a complete list of the titles of addresses of my predecessors. When it became evident that no such record was available, the title chosen offered its challenge.

1847 to 1876

At the first meeting of the American Medical Association in May, 1847, in Philadelphia, Nathaniel Chapman served as President. In that year Sir James Simpson introduced chloroform anesthesia in obstetrics, Semmelweis demonstrated the role of antisepsis in the prevention of puerperal fever, and Carl Ludwig invented the kymograph. Six years prior Oliver Wendell Holmes had written his paper on puerperal sepsis.

At the meeting held a year later in Baltimore, the Committee on Obstetrics reported "the anesthetic agents ether and chloroform have now been used in perhaps 2,000 cases of midwifery, and so far as the committee have been able to learn without a single fatal, and few, if any, untoward results."

In 1859 a Section on Practical Medicine and Obstetrics was authorized following a report introduced by J. B. Lindsley of Tennessee, who was chairman of the committee appointed to inquire into the propriety of dividing the Association into sections for the better performance of its work (see table).

The 1860 meeting of the Section on Practical Medicine and Obstetrics was called to order by N. S. Davis, of Chicago, and Amos Nourse was elected the first Chairman of the Section. In his A. M. A. presidential address, Henry Miller brought out openly the question of illegal abortion and urged action by legislatures in every state against this practice. The 1861 and 1862 meetings were canceled because of the Civil War. The following year there was a meeting in Chicago without sections.

In 1864 the A. M. A. met in New York City without Southerners and Nathan Smith Davis, founder of the A. M. A., was elected President. Fordyce Barker, who was Chairman of the Section on Practical Medicine and Obstetrics, later became the first President of the American Gynecological Society. The Secretary wrote: "several hundred members being present during the course of the meeting." Papers read included "Death from Air in the Circulation Introduced Through the Uterine Sinuses"; "A Modified Ring Pessary for the Treatment and Cure of Anteflexion and Anteversion of the Uterus"; "On the Use of Pessaries"; and "The Relations of Female Patients to Hospitals for the Insane: The Necessity on Their Account of a Board of Consulting Physicians to Every Hospital."

At the third meeting Zina Pitcher, who served as the 10th President of the A. M. A. and was thrice mayor of Detroit, occupied the chairmanship. H. R. Storer, of Boston, was awarded the A. M. A. gold medal for his essay entitled "The Criminality and Physical Evils of Forced Abortions." In the Section's minutes it is recorded that the Secretary commenced to read the paper of an absent member and, after the expiration of more than an hour, a motion was made to suspend its further reading and it was referred to a committee.

The program of the fourth annual meeting contained no obstetrics. There was a "Report of the Committee on Diphtheria as It Has Occurred in the United States" and one on "So-called Spotted Fever."

At the 1867 session the designation was the Section on the Practice of Medicine and Obstetrics. Included in the program was a paper entitled "Extra-uterine Foetation and Gestation, and the Early Signs Which Characterize It: Symptoms of the Fatal Hemorrhage into the Peritoneal Cavity, Its Usual Termination: Suggestions for the Positive Diagnosis of This Fatal Condition, and a Plan for the Treatment Indicated in It, with a View of

Saving the Life of the Woman." M. A. Pallen submitted a prize essay entitled "Treatment of Certain Uterine Abnormalities."

A year later a paper was read on "Tsa-Tsin, or Rhynchosa Excavata, as an Agent of Value in Amenorrhea and Dysmenorrhea," and it "elicited considerable discussion." Another paper, evidently the only other, "was referred to its author to report on more fully at the next meeting of the Association."

At the first New Orleans A. M. A. convention, the Section on the Practice of Medicine and Obstetrics had only medical subjects. In the Section on Anatomy and Surgery, Schuppert, of that city, presented "Remarks upon Some Points Referring to Success in the Operation of Vesico-vaginal Fistula." He said, ". . . bring a sufficient raw surface of the edges of the fistula in close coaptation, and whatever method of operation may be used is of minor importance. A surgeon without that proper skill will fail, whatever method or material he may employ; otherwise he will be successful, provided there is not a constitutional impediment in the patient or some obnoxious cause inimical to healing by first intention; accidents we meet so frequently in practice that it would seem rather strange to expect an exemption in this operation."

Those physicians assembled in the Capitol city in 1870 heard dissertations on "Intra-uterine Injections and Their Therapeutical Value," "Acute Puerperal Mania Treated by Hydrate of Chloral," and "Physiological Laws of Human Increase."

The initial conclave in San Francisco featured a paper on "Criminal Abortion," one on "The Social Evil," and a lengthy report submitted by the Criminal Abortion Committee which concluded with six excellent resolutions.

At the first meeting in Philadelphia one paper was entitled "Three Ovariotomists." Another was "On the Use of Fever and Surface Thermometers." One member "read a letter on a case of stricture of the vagina in a puerperal woman, and desired the opinion of the Section, which was given by several members."

At the 11th annual session of the Section, D. A. O'Donnell continued as Chairman. One topic for discussion was "the physiological anomalies in the configuration of the bony and soft parts of the pelvis, as a cause of retardation of labor." A paper on "The Granular Cell in Ovarian Fluid" was read. The title Section on Obstetrics and Diseases of Women and Children was to be used after this meeting.

The first Chairman's address was delivered in 1874 by Theophilus Parvin, who was A. M. A. President five years later. He spoke on "Uterine Hemorrhage," stating, ". . . it certainly will be one of the noblest triumphs of our divine art when, by an operation so rational, so simple, so speedy as transfusion, we can rescue woman just when she has passed through the profound sorrow of parturition, just when she is entering upon the supreme joy of maternity, from otherwise inevitable death." He emphasized prevention.

The next year Chairman Byford spoke on "Treatment of Fibrous Tumors of the Uterus by Ergot." He said:

> Recent writers, with few exceptions, teach the entire inefficiency of any form of treatment for the cure of intramural fibrous tumors of the uterus except by enucleation, and this operation is so dangerous and difficult as not to be thought of except in desperate conditions. . . . I conclude my address with the cautionary observation that ergot in the treatment of fibrous tumors of the uterus is a prompt and very powerful agent which cannot be recklessly used without great danger; and that much careful observation is still necessary to enable us to determine the circumstances under which its administration will be both safe and effective.

Marion Sims was the Independence Centennial Jubilee A. M. A. President. S. C. Busey served as the Section Chairman and related, "The written law of this Association limits this address to the discussion of the 'advances and discoveries of the past year,' in obstetric, gynesic and pediatric medicine. However willing or competent I might be to fill the measure of this requirement, the time allowed me would necessarily preclude a critical examination of all the contributions to this department. Nor would this be desirable, since many of them are mere novelties of little or no value, or hasty promulgations of immatured opinions and illogical conclusions." He then proceeded to give an excellent review of the recent literature and lists some 81 references. Referring to an article on the substitution of electrolysis for ovariotomy he said, "So successful has this method proven in the practice of Dr. Semeleder that I hesitate to accept his statement, and am startled at the thought that the greatest triumph of modern surgery is to be superseded by a process so simple and so painless."

1877 to 1887

Chairman James P. White referred to some of the "advances and discoveries of the past year" in his 1877 address. He spoke highly of and predicted a great future for the American Gynecological Society, founded in September of the preceding year. He stated, "In conclusion, I beg to call the attention of this Association to the great neglect on the part of the schools in clinical teaching in obstetrics, and in the diseases of the generative organs. There is no subject in the whole college curriculum which so imperatively demands bedside observation as the process of parturition."

In 1878 Edward W. Jenks spoke on "The Causes of Sudden Death of Puerperal Women," listing numerous references, including one to "the late Professor Charles D. Meigs," who in 1849 in the *Philadelphia Medical Examiner* directed "attention to the possibility of spontaneous coagulation of the blood in the right side of the heart and pulmonary arteries as a cause of death in the puerperal state." In conclusion he stated that the mortality due to puerperal convulsions during the last 20 years had been reduced from 32 to 14% and said, "This is but one illustration of what has been done by our science and art in the past, but it is a significant prophecy of what we may expect in the future."

Chairman Ernest S. Lewis, in 1879, discussed "Abdominal Palpation," "Antiseptic Management in Labor," "Puerperal Fever," "Laparo-elytrotomy," "Primary Conversion of Occipito Posterior into Occipito Anterior Position," "Post Partum Hemorrhage," and advances and progress in "Gynecic-Surgery," including "Censure and Condemnation of Total Extirpation of the Uterus in Cancer," and quoted the brilliant successes of Freund and Schroeder in surgical treatment of cancer. He included a section on "Uterine Fibroids" in his address.

The 1880 Chairman was absent; consequently, G. M. B. Maughs, of Missouri, served pro tem. The Section dropped "and Children" from its name so that it became known as the Section on Obstetrics and Diseases of Women. Papers given included "Battey's Operation in Epileptoid Affections"; "The Management of the Third Stage of Abortion, with Retention of Placenta and Membranes"; and "A Clinical Contribution to the Subject of Removal of the Uterus, in Whole or in Part, for the Extirpation of Tumors Connected with That Organ."

James R. Chadwick chose as his title "Obstetrics and Gynaecological Literature, 1876-1881." He mentioned that the *American Journal of Obstetrics and Diseases of Women and Children* was first published in 1869. He also listed the titles of other periodicals devoted to obstetrics and gynecology published in America and in eight other countries, with dates founded. One table was labeled "Analysis of the Literature of the Year 1880 by Nationalities."

The next Chairman was H. O. Marcy, A. M. A. President 10 years later, who discussed "Fibroid Tumors of the Uterus." He stated, "The peritoneal cavity is no longer the *terra incognita* of the surgeon, nor its invasion attended with the fears or dangers of even a very recent period." He said the growths should be classified as myomas and discussed the various methods of treating them in his thorough and comprehensive presentation.

1883 was the birth year of THE JOURNAL of the American Medical Association. Chairman J. K. Bartlett's address, "Topics in Gynecological Surgery," included discussion of "Extra Uterine Pregnancy," for which he recommended galvanism over faradism. He also advocated its use in such conditions as "Dysmenorrhea" and "Post Partem Hemorrhage."

Meetings of the Section

Place	Year	Chairman
Louisville, Ky.	1859	Section on Practical Medicine and Obstetrics authorized
New Haven, Conn.	1860	Amos Nourse, Maine
	1861	Meeting canceled because of war
	1862	Meeting canceled because of war
Chicago	1863	No section meetings
New York	1864	Fordyce Barker, New York

Saving the Life of the Woman." M. A. Pallen submitted a prize essay entitled "Treatment of Certain Uterine Abnormalities."

A year later a paper was read on "Tsa-Tsin, or Rhynchosa Excavata, as an Agent of Value in Amenorrhea and Dysmenorrhea," and it "elicited considerable discussion." Another paper, evidently the only other, "was referred to its author to report on more fully at the next meeting of the Association."

At the first New Orleans A. M. A. convention, the Section on the Practice of Medicine and Obstetrics had only medical subjects. In the Section on Anatomy and Surgery, Schuppert, of that city, presented "Remarks upon Some Points Referring to Success in the Operation of Vesico-vaginal Fistula." He said, ". . . bring a sufficient raw surface of the edges of the fistula in close coaptation, and whatever method of operation may be used is of minor importance. A surgeon without that proper skill will fail, whatever method or material he may employ; otherwise he will be successful, provided there is not a constitutional impediment in the patient or some obnoxious cause inimical to healing by first intention; accidents we meet so frequently in practice that it would seem rather strange to expect an exemption in this operation."

Those physicians assembled in the Capitol city in 1870 heard dissertations on "Intra-uterine Injections and Their Therapeutical Value," "Acute Puerperal Mania Treated by Hydrate of Chloral," and "Physiological Laws of Human Increase."

The initial conclave in San Francisco featured a paper on "Criminal Abortion," one on "The Social Evil," and a lengthy report submitted by the Criminal Abortion Committee which concluded with six excellent resolutions.

At the first meeting in Philadelphia one paper was entitled "Three Ovariotomists." Another was "On the Use of Fever and Surface Thermometers." One member "read a letter on a case of stricture of the vagina in a puerperal woman, and desired the opinion of the Section, which was given by several members."

At the 11th annual session of the Section, D. A. O'Donnell continued as Chairman. One topic for discussion was "the physiological anomalies in the configuration of the bony and soft parts of the pelvis, as a cause of retardation of labor." A paper on "The Granular Cell in Ovarian Fluid" was read. The title Section on Obstetrics and Diseases of Women and Children was to be used after this meeting.

The first Chairman's address was delivered in 1874 by Theophilus Parvin, who was A. M. A. President five years later. He spoke on "Uterine Hemorrhage," stating, ". . . it certainly will be one of the noblest triumphs of our divine art when, by an operation so rational, so simple, so speedy as transfusion, we can rescue woman just when she has passed through the profound sorrow of parturition, just when she is entering upon the supreme joy of maternity, from otherwise inevitable death." He emphasized prevention.

The next year Chairman Byford spoke on "Treatment of Fibrous Tumors of the Uterus by Ergot." He said:

> Recent writers, with few exceptions, teach the entire inefficiency of any form of treatment for the cure of intramural fibrous tumors of the uterus except by enucleation, and this operation is so dangerous and difficult as not to be thought of except in desperate conditions. . . . I conclude my address with the cautionary observation that ergot in the treatment of fibrous tumors of the uterus is a prompt and very powerful agent which cannot be recklessly used without great danger; and that much careful observation is still necessary to enable us to determine the circumstances under which its administration will be both safe and effective.

Marion Sims was the Independence Centennial Jubilee A. M. A. President. S. C. Busey served as the Section Chairman and related, "The written law of this Association limits this address to the discussion of the 'advances and discoveries of the past year,' in obstetric, gynesic and pediatric medicine. However willing or competent I might be to fill the measure of this requirement, the time allowed me would necessarily preclude a critical examination of all the contributions to this department. Nor would this be desirable, since many of them are mere novelties of little or no value, or hasty promulgations of immatured opinions and illogical conclusions." He then proceeded to give an excellent review of the recent literature and lists some 81 references. Referring to an article on the substitution of electrolysis for ovariotomy he said, "So successful has this method proven in the practice of Dr. Semeleder that I hesitate to accept his statement, and am startled at the thought that the greatest triumph of modern surgery is to be superseded by a process so simple and so painless."

1877 to 1887

Chairman James P. White referred to some of the "advances and discoveries of the past year" in his 1877 address. He spoke highly of and predicted a great future for the American Gynecological Society, founded in September of the preceding year. He stated, "In conclusion, I beg to call the attention of this Association to the great neglect on the part of the schools in clinical teaching in obstetrics, and in the diseases of the generative organs. There is no subject in the whole college curriculum which so imperatively demands bedside observation as the process of parturition."

In 1878 Edward W. Jenks spoke on "The Causes of Sudden Death of Puerperal Women," listing numerous references, including one to "the late Professor Charles D. Meigs," who in 1849 in the *Philadelphia Medical Examiner* directed "attention to the possibility of spontaneous coagulation of the blood in the right side of the heart and pulmonary arteries as a cause of death in the puerperal state." In conclusion he stated that the mortality due to puerperal convulsions during the last 20 years had been reduced from 32 to 14% and said, "This is but one illustration of what has been done by our science and art in the past, but it is a significant prophecy of what we may expect in the future."

Chairman Ernest S. Lewis, in 1879, discussed "Abdominal Palpation," "Antiseptic Management in Labor," "Puerperal Fever," "Laparo-elytrotomy," "Primary Conversion of Occipito Posterior into Occipito Anterior Position," "Post Partum Hemorrhage," and advances and progress in "Gynecic-Surgery," including "Censure and Condemnation of Total Extirpation of the Uterus in Cancer," and quoted the brilliant successes of Freund and Schroeder in surgical treatment of cancer. He included a section on "Uterine Fibroids" in his address.

The 1880 Chairman was absent; consequently, G. M. B. Maughs, of Missouri, served pro tem. The Section dropped "and Children" from its name so that it became known as the Section on Obstetrics and Diseases of Women. Papers given included "Battey's Operation in Epileptoid Affections"; "The Management of the Third Stage of Abortion, with Retention of Placenta and Membranes"; and "A Clinical Contribution to the Subject of Removal of the Uterus, in Whole or in Part, for the Extirpation of Tumors Connected with That Organ."

James R. Chadwick chose as his title "Obstetrics and Gynaecological Literature, 1876-1881." He mentioned that the *American Journal of Obstetrics and Diseases of Women and Children* was first published in 1869. He also listed the titles of other periodicals devoted to obstetrics and gynecology published in America and in eight other countries, with dates founded. One table was labeled "Analysis of the Literature of the Year 1880 by Nationalities."

The next Chairman was H. O. Marcy, A. M. A. President 10 years later, who discussed "Fibroid Tumors of the Uterus." He stated, "The peritoneal cavity is no longer the *terra incognita* of the surgeon, nor its invasion attended with the fears or dangers of even a very recent period." He said the growths should be classified as myomas and discussed the various methods of treating them in his thorough and comprehensive presentation.

1883 was the birth year of The Journal of the American Medical Association. Chairman J. K. Bartlett's address, "Topics in Gynecological Surgery," included discussion of "Extra Uterine Pregnancy," for which he recommended galvanism over faradism. He also advocated its use in such conditions as "Dysmenorrhea" and "Post Partem Hemorrhage."

The next year Thaddeus A. Reamy said, "The editorial criticisms of new doctrines, discoveries, methods, or operations are generally from the pens of those who, by education and special training, have superior abilities for such work. It is, therefore, deemed appropriate on the present occasion, to refer you for an 'Annual Report on Obstetrics and Diseases of Women' to these more fertile and instructive sources . . . . Craving your indulgence, I beg to offer, in lieu of such an address, 'Notes on Two Hundred and Thirty-One Cases of Operation for Laceration of the Cervix Uteri.'" He included discussion of the possibility of cancer originating in lacerations.

R. S. Sutton, M.D., LL.D., in "A Brief Review or the Growth of McDowell's Operation Done at Danville, Kentucky, in 1809: Its Present Status," emphasized that the solitary exception to the original procedure at the end of almost three-quarters of a century was that the ends of the pedicle ligature were being cut short. He eulogized J. Marion Sims, who died in 1884.

S. C. Gordon spoke on "Hysteria and Its Relation to Diseases of the Uterine Appendages." His advocacy of surgery was strong. Although he stated that it was impossible in a majority of cases to determine by touch diseases of organs that produce symptoms, he said that the specimens removed were usually severely pathologically altered.

After stating, "The past year has given few, if any, remarkable discoveries, either in gynecology or obstetrics," F. M. Johnson proceeded to discuss "Ovariotomy," "Hot Water in Shock," "Cocaine in Gynecology," "Caesarean Section" (on which he looked with favor, especially the Sanger-Leopold operation), and "New Pathology in Labor," in which he stressed the etiological relationship between pregnancy and kidney disease, with theories on eclampsia.

1888 to 1899

Chairman Ely Van De Warker spoke on "How Gynecology Is Taught," at the 1888 meeting. The Society Proceedings of the A. M. A. disclose that amendments were offered by H. N. Moyer, including: "The Section of Surgery shall hereafter be denominated the Section of Surgery and Gynecology. The Section on Obstetrics and Diseases of Women shall be abolished. The Section on Diseases of Children shall hereafter be denominated the Section of Obstetrics and Paediatrics."

Under Domestic Correspondence in The Journal of the American Medical Association, June 8, 1889, there is an unsigned letter entitled "Shall the Section of Obstetrics and Diseases of Women Be Abolished?" which emphasized "both the study and practice of obstetrics and gynecology must remain so correlated that they can only be successfully cultivated conjointly. To abolish this Section of the Association, now so successfully conducted, would scatter the members into other crowded Sections, and do the cause of science and the Association serious injury." The official report of the next meeting, which was held in Newport, R. I., appears in The Journal, July 20, 1889, revealing that a motion to lay the proposed amendments on the table and indefinitely postpone was carried by a large majority. W. H. Wathen presided at the Section meeting, speaking on "Pathology of Ectopic Pregnancy and Pelvic Hematocele."

Chairman William Warren Potter, who was the first secretary of the American Association of Obstetricians and Gynecologists (1888), spoke on some advances during the previous year and suggested that the By-Laws be amended to create a vice-chairmanship, the Secretary's tenure be longer than a year, and the proceedings be published in a separate volume, including stenographic reporting of discussions. Tarnier's traction forceps were referred to as "ingenious and useful." Potter quoted the mandate of the Apostle, "Prove all things; hold fast that which is good."

C. A. L. Reed, the 53rd A. M. A. President, was the 1891 Chairman. Although the *Transactions of the Section on Obstetrics and Diseases of Women* commenced that year, they do not include an address by him, nor have we found it elsewhere. In his biography by Walter L. Bierring, we find him described as "one of the most interesting and dynamic figures in American medicine." The program included "Relation of Gynaecology to Neurology"; "Rapid Dilatation and Curetting"; "Pathological Anteflexion of the Uterus"; Practical Experience in the Treatment of Accidental Abortion"; "Prevention of Puerperal Eclampsia by the Induction of Premature Labor"; "The Operative Treatment of Extra-uterine Pregnancy at or Near Term, with Report of a Case"; and "Extra-uterine Pregnancy."

E. E. Montgomery presented an address on "Some Mooted Points in Obstetrics and Gynecology" the following year. He advocated Braxton Hicks version in cases of placenta previa, reporting a fetal mortality of 70 to 80% and a maternal mortality of 6 to 7%. In discussing "hysterectomy versus supra vaginal hysterectomy in fibroid growths," he recommended total hysterectomy. He referred to two cases of hysterectomy done through sacral resection "with gratifying results."

John Milton Duff gave no formal title but made general references to the objectives of the meetings. Regarding the work of the previous year, he reported it "not characterized by much that was unique or peculiarly brilliant and original." He advised early and prompt therapy for placenta previa, stating that watchful expectancy is "utter absurdity." For puerperal infection he recommended asepsis with early and vigorous treatment, stating that the death rate (2½%) was declining.

In his oration on suprapubic hysterectomy as viewed from the standpoint of personal observation and clinical research, Chairman Joseph Eastman said:

> The century which in a few years will have rolled on to the eternal past, has placed in the magnificent temple of medicine many pillars of surpassing beauty and grandeur, while its surgical columns have risen high toward Heaven where as gilded towers, they fain would vie with the God-given sunshine in dispelling the chill and gloom of human agony.
>
> Chirurgia's tower, thy lights resplendent blaze
> Dries woman's tears, and lengthens out her days;
> McDowell and Sims of our Columbia's clime
> Began the work moved onward nigh sublime.
> To women, then, these blessings shall be given—
> Queen of the home and home the type of Heaven.
>
> Abdominal surgery is *proud* of her past because it is prophetic of her *future*. Even now in the vital present it shall stand forth unchallenged as the crowning glory of all science and of all art.

F. H. Martin's address was on "Some Mooted Points in Pelvic Surgery." He used galvanism in "desperate" cases but said, ". . . in the present state of pelvic and abdominal surgery, I would not voluntarily administer or recommend Galvanism for fibroid tumors, the subjects of which were under 40 years of age, whose tumors were suitable for operative procedures, and whose general health would show an average chance for favorable surgery." He favored hysterectomy instead of removal of the appendages for fibroids, discussed vaginal ligation of the broad ligament to check uterine hemorrhage and to cause atrophy of uterine tumors, stressed the importance of renal evaluation prior to surgery, and recommended silk and antiseptic absorbable ligatures for intra-abdominal operations. He was the first secretary-general of the American College of Surgeons, being one of its founders in 1913.

Joseph Taber Johnson keynoted his remarks on "Puerperal Infection" by emphasizing prevention, namely, "cleanliness and ventilation." He favored the treatment of Lush of New York, who stated, "The more these cases are let alone and the more simple the treatment the more likely they are to get well." He declared, ". . . when the placenta is praevia the uterus should be emptied," as there is "no wisdom or safety in delay." When the cervix was dilated, Braxton Hicks method was advocated. He advised hysterectomy for control of hemorrhage. He gave his reasons for favoring vaginal hysterectomies as "completeness, drainage, avoidance of shock by less handling of intestines, less peritoneal infection, no abdominal wound, and less liability to hernia." In closing he said, "The present Chairman hopes that his successor may be able to report good developments and improvements in the diagnosis of abdominal and pelvic diseases of women, from the evolution of 'x-rays' about which we have heard so much of late. If its promises are fulfilled we ought to find little difficulty hereafter in our diagnosis of extra uterine pregnancy, pyosalpinx, fibroid, dermoid or ovarian tumors."

Milo B. Ward, who occupied the Chair at the Semi-Centennial meeting, reviewed "some of the work which has been accomplished during the last half-century by way of a more accurate comprehension of the etiology, pathology and treatment of diseases of women by our American profession." He said, "The administration of glandular extracts after the removal of uterine appendages and in conditions demanding nutritive tonics, is attracting much attention and [they] are considered by many who have used them to possess much value."

Joseph Price, who spoke of unjust and great opposition to new ideas and techniques, said, "The young school of gynecologists have unfortunately lost interest or neglected plastic surgery." Wider use of pessaries and rest treatment for displacements were advised. He warned, "Be not deterred by false sentiment or the jealousies of those who would rather keep their patients in their own hands than see them cured by others from doing what we know to be our duty." He condemned the current methods of teaching, saying, "the student should be given that which will enable him, when he goes home, to go to work and do good work."

A. H. Cordier praised the A. M. A. meetings, his predecessors and the work of the past. He stressed need for early diagnosis and referred to use of "streptoserum" and "ointment of silver" in puerperal infections.

1900 to 1910

At the beginning of the 20th century, W. E. B. Davis praised asepsis and stressed the need for the use of rubber gloves. He elaborated on the truthfulness of the quotation: "Obstetrics married surgery and the fruit of their union was bright eyed gynecology." He condemned general surgeons for doing gynecologic and obstetric surgery and praised various specialty organizations and their journals. The place of myomectomies was recognized, but hysterectomy was generally considered to be better. He paid honor to Kelly but did not agree with his treatment of "pus in the kidneys through the ureter." The fact that the New York State Medical Society was not then in affiliation with the Association was bemoaned.

Henry P. Newman briefly traced the history of anesthesia by lumbar puncture and recognized it as an anesthetic method but said that the psychic trauma to women "consciously undergoing major operations upon their own viscera and witnessing details of its occurrence" detracted from its usefulness. He thought it was unreliable in obstetrics. His discussion included "Protozoon of Cancer"; "Removal of Lymphatics," in which he referred to Wertheim; "Ovarian Transplantation"; Vinot's work on "Tubal Epithelium"; and "Permeability of the Amnion." The following quotations are from his address: "Nothing could be more disastrous to the worth and dignity of this specialty, which has occupied for so long so honorable a place in medicine, than to allow itself to be considered and spoken of as one of the surgical specialties." "We are but just arriving at the threshold of the greatest era in our history, in which the full value of prophylaxis is being recognized, and gynecological knowledge and experience are to be the re-creator and conservator of health in women." "There will always be need for intelligent obstetrics while intelligent gynecology should eliminate itself at last by eliminating those conditions which are the cause of disease in women and its only excuse for being. Nothing but gynecology can eliminate gynecology."

J. H. Carstens spoke on "What of the Future?" He said:

> . . . Most questions in the obstetric part of our Section have virtually been settled and those in gynecology are being rapidly settled. Very soon there will be nothing to write about. . . . We should insist that gymnastics and systematic physical exercise should be taught in every school of the land, from the lower to the highest, and that the curriculum of study should embrace the most systematic course of gymnastics to produce a sound body with a sound mind. We should thoroughly study the effects and the results of erotism on the human body. We should study how we can more thoroughly bring about a more perfect marriage relationship and prevent the frequent mismating as shown in our courts. . . . In fact we must more thoroughly study the exact positions of individuals, every combination of physical and mental condition, and their most fit place and proper vocation in life. We must branch out, we must look ahead, we must be counsellors and the guides of the race in the future.

In discussing "The Trend of Gynecologic Work To-day," A. Palmer Dudley said, ". . . with the advent of Lister the Mephistopheles of surgery vanished from view. Fear no longer haunted the mind of operator or patient, and the peritoneum, the bugbear of former years, seemed to readily acquiesce in the evolution. With this confidence in the restorative powers of human nature came the reckless disregard of the consequences in the future." He stated that in 1887 he began "a series of experimental operations on the uterine appendages, which, strictly speaking, was more radical than a hysterectomy, because it trusted such surgical work on the appendages to the efforts of nature for a cure, while the ultimate results were more conservative to the woman, because by the skill of the surgeon and the aid of nature she had been restored to health, and could still consider herself a woman." Due credit was given to Carl Schroeder (1885) as being the pioneer. He said, "In doing conservative surgery on the tubes and ovaries the first thing to do is to endeavor to put the inside of the uterus into a condition to become healthy. If plastic work on the genital canal is necessary, this must be done also. Then open the abdomen and do what work is indicated in each individual case." He classified ventrofixation as a pernicious procedure differing markedly from suspension, the postoperative care of which he narrated.

L. H. Dunning included in "Remarks on Advances in Gynecology During the Last Year" the statement that treatment must be based on ideas of etiology and pathology; consequently, more work was warranted in those fields. He praised the work of Jenner, Pasteur, Koch, Lister, and Tate in discovering many sources of infection and said, "The moral is, let each man find an unsolved problem within the scope of his attainments, and then set himself deliberately and persistently to the task of its solution." He presented an excellent discourse on senile endometritis, and one of his photomicrographs was in color.

C. L. Bonifield commented that the office of the Secretary should be comparatively permanent and that the latter should be relieved of the necessity of disposing of bound volumes of the transactions and should be remunerated for his expenses. He suggested that the number of papers to be read be limited to 30, with only 15 minutes for each paper, and that the longer papers be read in abstract. He recommended changing the name to Section on Obstetrics, Diseases of Women and Abdominal Surgery, with 10 papers allotted to each branch. In discussing "Important Subjects Which Have Occupied the Attention of Gynecologists and Obstetricians During the Past Year," he included surgical and nonsurgical treatment of displacements of the uterus; surgery for cancer, stating that extensiveness of the operation depends on many factors; toxemia of pregnancy, recommending Veratrum viride; and vaginal cesarean section, advised in suitable cases. He also recommended that more work be done on sterility.

"The Legal Responsibility of the Physician for the Unborn Child" was the title used by C. S. Bacon. All physicians were advised to understand their lawful rights and obligations and to have a definite understanding or contract with patients. The fact that the unborn child must be regarded as another human being was emphasized. Consultations were advocated. He said, "In general it might be affirmed that the indications for destructive operations are becoming contracted and many pathologic states that previously were treated by embryotomy, would not now be accepted as indications."

J. Wesley Bovée directed attention to "The Status of the Fight Against Cancer." He discussed occurrence, classification, etiology, and treatment. Among his conclusions were that women should be educated as to signs and symptoms; there should be special care in classification; x-rays and radium are of little use in early cases, in which surgery is best;

radical surgery affords the best results; animal experimentation is promiseful; the vaginal route is not best for total irradiation; there are reasons to believe the disease can be controlled; and cancer should be regarded as contagious.

Walter B. Dorsett's lengthy address on "Criminal Abortion in Its Broadest Sense" was discussed by many participants. He advocated the obligatory teaching of medical jurisprudence and medical ethics in medical colleges, the enactment of good and sufficient laws and the amendment of insufficient laws now on statute books, and the appointment by the A. M. A. President of a Committee on Criminal Abortion for the purpose of attaining better laws through appointed state committees to work with their respective legislatures.

"Mental Alienation in Women and Abdominopelvic Disease" was W. P. Manton's subject. He said, "I and others have demonstrated that relief from suffering brings about a mental palliation often otherwise unobtainable." He believed that mental disease often stemmed from pelvic disorders but noted that it could occur without underlying physical pathology and that operative repair or restoration of the pelvic picture to normal was not always followed by a cure of the mental picture.

John G. Clark's "The Surgical Consideration of Congenital and Developmental Defects Leading to Obstinate Constipation" was so lengthy that a part was deleted prior to publication in The Journal. He recommended diagnosis by detailed clinical history and skiagraph. His admonition was that this kind of surgery is not for the novice.

1911 to 1920

1911 brought a change in title to Section on Obstetrics and Gynecology, and H. G. Wetherill spoke on "Retrospection and Introspection: Our Opportunities and Obligations." The closing paragraph was, "The crystallization and concentration of ideas, the simplification of practice, and the determination of what not to do, that we have done before, is progress of the best sort. Though this may not be our banner constructive period, it will be none the less valuable to humanity if we learn to see our mistakes of the past and to avoid them in the future."

The following year, under the chairmanship of C. Jeff Miller, "and Abdominal Surgery" was added to the name of the Section. In his dissertation on "The Present Status of Ligation or Excision of the Pelvic Veins in the Treatment of Septic Thrombophlebitis of Puerperal Origin" he said:

> The task of formulating the indications for the surgical treatment of puerperal infection still affords a source of prolific discussion. It seems impossible to agree on established rules as has been done in suppurative appendicitis, gall-bladder infection, or suppurative otitis media. Some of the confusion has undoubtedly arisen from the fact that we have no reliable clinical or laboratory guide to aid us in determining a reasonable prognosis, from the difficulty of differentiating the complex lesions, and to a certain extent, from the antipathy for serious surgical operations on the lying-in woman. It must be said, however, that our ideas are gradually crystallizing, that conservatism prevails, and that, owing to a better conception of puerperal processes in general, surgical measures adopted with more care and discrimination. During the past ten years the possibility of saving by operation the lives of women suffering from puerperal pyemia has received a great deal of attention. The idea is by no means new, as John Hunter suggested it, and scattered reports of successful ligation of the veins of the extremities can be found in the literature of the middle of the past century. The meager material at our command, reported by numerous operators, who have operated without definite indications and without a definitely established technic is sufficient to show that the procedure is feasible and should be given a fair and unbiased trial in septic thrombophlebitis.

1913 brought the birth of the American College of Surgeons, about the formation of which F. F. Simpson stated, ". . . it marks the beginning of a new era in American surgery. Its essential purpose is to encourage the development of sound surgical judgment to render surgeons more skilful and to make surgery more safe. It is not to be an exclusive, but an inclusive organization. It hopes to number among its fellows every one who does safe, sound and honest work." His lengthy address was on "Right-Sided Hypertension with Occasional Cardiac Dilatation as Postoperative Complications." At that meeting W. Wayne Babcock read a meritorious paper on "Spinal Anesthesia in Gynecology, Obstetrics and Abdominal Surgery."

E. Gustav Zinke's title was "A Few Points of Practical Importance in Obstetrics, Gynecology and Abdominal Surgery." He included discussion of "Intestinal Stasis," "Painless Operations," "Roentgen-Ray Therapy" (stating that although good results were obtained on fibroids, surgery was the treatment of choice), "Curative Effect of Radium," "Percy Treatment of Inoperable Carcinoma Uteri," "The Compromise Operations of Obstetrics," "The Treatment of Placenta Praevia" (advising case individualization); and "The Merits of Surgery in the Management of Puerperal Eclampsia," in which he reprimanded a writer who had recently stated the mortality rates were equal in hysterotomy or medical management. He favored use of such agents as Veratrum veride.

Thomas S. Cullen gave a panoramic view of "The Relation of Obstetrics, Gynecology and Abdominal Surgery to the Public Welfare" as he saw them 25 years prior and compared them to those of 1915. In his conclusions are the following statements: "Obstetrics must be made more attractive so that those entering this branch will not be tempted to leave it for less laborious fields." "Any Surgeon opening an abdomen should be capable of doing everything necessary in that abdomen. In other words gynecology and abdominal surgery logically belong together."

Edward Reynolds' scientific address on "Fertility and Sterility, Histologic Study of Spermatozoa, the Ovaries, and the Uterine and Vaginal Secretions in Their Relation to This Question," was well illustrated with photomicrographs.

Howard W. Longyear's discourse on "The Relations of Gynecology to General Surgery, Past and Present" emphasized that gynecology belonged to general surgery. He said:

> The Twentieth Century is ushering in a period of kaleidoscopic changes, of Aladdin-like transformations in everything pertaining to the activities of man. Science, the arts, business, society, finance, methods of warfare—all are feeling the jolts of the erratic and rapid pace of this great evolutionary present-day thrust. We are living in a new world in which habits and customs, venerated by centuries of usage, are dropped without ceremony and without apparent effort or regret, and the new blithely taken on, all in the name of progress. The horse bids fair soon to become extinct as a domestic animal, perhaps to revert to the wild state of his ancestors and be captured and exhibited by future generations of man as a curiosity, along with the gnu, zebra and giraffe.

Brooke M. Anspach's discussion of "Enterostomy and Enterocolostomy in the Treatment of Acute Intestinal Obstruction Following Pelvic Operations" concerned prevention, causes, stages, source of toxemia, and operative measures. He reported five cases illustrated with diagrams.

Thomas J. Watkins referred to the 70th A. M. A. Convention as the "Victory Meeting." He declared, "Democracy has defeated Autocracy." His subject was "Progress in Obstetrics, Gynecology and Abdominal Surgery." He said, "Study of the ductless glands has elucidated much hitherto obscure symptomatology of gynecologic cases, and has opened up a fertile field for further investigation. Radium has proved to be a remedy of great value. Much has been said relative to the practice of surgery by men with insufficient training. It it not my purpose or intent to offer any excuses for them, but to call attention to the fact that some of the responsibility for poor surgery rests elsewhere, especially with the men accountable to medical institutions of learning."

Reuben Peterson emphasized in his address on "The Future of Obstetrics and Gynecology as a Specialty" that they be combined. He condemned the tendency for gynecology to be linked with general surgery but stated that obstetricians and gynecologists must be able and prepared to cope with general surgical problems when they open the abdomen for pelvic disease. "Actual experience and technical skill in abdominal as contrasted with obstetric and gynecologic surgery should be acquired in departmental hospital clinics by cooperation with the general surgical clinics. . . . In fact, this principle of free interchange of services should not be confined to surgery alone, but should apply to all departments of the hospital, where such an arrangement will make for better training in obstetrics and gynecology."

1921 to 1929

John Osborn Polak discussed "The Defects in Our Obstetric Teaching." He recognized the decrease in many conditions "to an almost irreducible minimum" but stated, "Contrast this with the fact that the number of women who die from childbirth is increasing from year to year and that puerperal septicemia seems to be the only form of wound infection the occurrence of which has remained wholly unaffected in the past decade by the advancement of scientific knowledge." He praised classroom instruction but condemned lack of clinical observation in medical schools. "I feel that it is time that the public be taken into our confidence and taught what can be done by prenatal care and clean obstetrics; for good obstetrics would go far toward removing the horrors of childbirth and the consequent dread of invalidism. More than 61 per cent of all gynecologic surgery is the direct result of poor obstetric practice."

"Some Gynecologic Misdemeanors," a paper by Sidney A. Chalfant, contains the statement, "It is far from my intention to give the impression that my criticisms apply to the profession as a whole. There is no finer class of men, or men more conscientious, devoted, and skilful than the medical profession of America." For correction of evils, he advised more careful selection of medical students, more systematic instruction of students in history of medicine, so that they will have the inspiration derived from achievements of the past and receive inspiration for their own work; sufficient and efficient postgraduate schools for training the ambitious; and education of the public as to the necessity of obtaining competent surgical advice.

In his address "Abdominal Surgery Without Detached Pads and Sponges," Harry S. Crossen said, "A sponge left in the peritoneal cavity following an operation constitutes one of the most deplorable accidents of abdominal surgery." He mentioned the increasing number of lawsuits. His method, by which removal of gauze is automatic, was described by narration and eight figures.

Under the title "The Specialty of Gynecology," Frank W. Lynch reviewed the status quo, prognosticated, and outlined a plan of proper training in the future. He stated that gynecology was first to react to surgical possibilities and related how it developed along surgical lines. In his opinion obstetrics needed "a more conservative companion than general surgery." He emphasized the need of well-developed departments in medical schools in which obstetrics and gynecology are taught as interdigitating parts of one major division under control of one head. Close correlation between the clinic, ward, laboratory, operating and delivery rooms, and follow-up studies were recommended.

In the *Transactions of the Section* we find that the 1925 meeting was called to order by Vice-chairman H. C. Bailey. Apparently Chairman Rudolph W. Holmes was absent. The program included papers on tuberculosis of the vagina; distribution of the ovarian follicular hormone in human genital tissues; the average sex life of American women and the relation between experiences and genital findings; dilatation of the ureter and kidney pelvis during pregnancy; radium treatment of carcinoma of the cervix uteri: results at the Woman's Hospital, New York, after five years; the surgical treatment of varicose veins of the female pelvis; intracranial hemorrhages in the newborn; pelvimetry of the superior strait by means of the roentgen ray; and the treatment of hyperemesis gravidarum by intravenous injections of glucose and carbohydrate feedings.

George Gray Ward in his presentation, "Our Obstetric and Gynecologic Responsibilities," said, "This specialty comprises the study of the physiology and pathology of the reproductive system of woman, and as such should be considered in toto. There is a great need of propaganda to awaken the profession to the fact that obstetrics, as generally practiced at the present, is woefully below the standard that maternity hospital statistics show." He pointed out that septicemia, toxemia, and hemorrhage are responsible for 58% of deaths and are preventable. Condemning practice of bad obstetrics, he stated, "He who attempts to make nature deviate from her normal physiologic processes must remember that, while he may accomplish his immediate object, it is very apt to be at an exorbitant price. Patience is the better obstetrician, in the majority of cases, than dexterity." He emphasized the need of better teaching and training. A classification of wound healing was given. In conclusion he stated:

> I have said that our present shortcomings in obstetric practice must be due to inadequate teaching or a lack of conscience. . . . As to the second cause of our delinquency, what we need today is an awakening of our surgical conscience. Longyear has reminded us that skilful surgeons may not all be conscientious, and conscientious surgeons may not all be skilful. A full appreciation of this can best be brought to our attention by a proper audit of our results. To awaken our conscience, we must be made to appreciate the existing facts by bringing them out into the spotlight—to this end there is no answer but the word "audit." We must audit the morbidity statistics as well as the mortality statistics of our clinics as systematically and accurately as we do our finances —then only shall we see the light that will stimulate us to live up to our obstetric and gynecologic responsibilities.

Discussing "Indications for Surgical Intervention in Pelvic Lesions of Infectious Origin: Based on Seventeen Years of Laboratory and Clinical Study," Arthur H. Curtis included special features of vaginal discharges, endocervicitis, endometritis, and inflammation of the adnexa. He cautioned about operating for sterility alone and mentioned that for years he had tested tubal patency from within the abdomen with air. Conservative surgery was advised, and it was stated that at the time of operation the decision relative to disposition of the ovary required consideration of etiology of pelvic infection and that even though a hysterectomy was indicated the ovaries of young women should be left in situ unless one was dealing with tuberculous or streptococcic infection. He said that operative intervention should be avoided in patients with acute tubal inflammation.

Jennings C. Litzenberg spoke on "Obstetrics and Gynecology in Public Health Program," stating, "Enough facts and procedures are known to reduce the deaths of women by thousands every year if the profession would only apply the knowledge it already has. Why, in the name of humanity, it does not or will not is an enigma. There are enough lives lost which cannot be saved by anything known to medical science. May no more be added to these by neglect." In tabular form he showed the change in the death rate in the United States (1915-1925) as follows: Total puerperal deaths —2%, puerperal infection —11%, eclampsia +5%, cancer of female generative organs +12%, tuberculosis —40%, early infancy —20.5%, prematurity +10%, and birth injuries +14.8%.

Carl Henry Davis chose the subject "Obstetrics and Gynecology in General Practice." He commented on the development of anesthesia and analgesia in obstetric practice; devoted four paragraphs to the "Early History of the Section"; discussed "Maternal Mortality in the United States," saying, "puerperal sepsis still remains the greatest single cause"; and pointed out that "specialists in obstetrics and gynecology were almost unknown eighty years ago. While today there may be one or more in cities of 50,000 or larger, the care of women and children still remains a very important problem of the general practitioner." The need for more and better teaching of obstetrics was emphasized. He discussed "The Training of the General Practitioner" and summarized the conditions believed essential in the effort to obtain better medical care for women patients as follows:

> Governmental activities should be directed toward a careful survey of the causes of maternal and infant deaths in the United States and an investigation of methods that may be adaptable to various local conditions. Medical students who go into general practice after graduation require more adequate clinical training in obstetrics. More institutions are needed in which physicians who wish to specialize in obstetrics and gynecology may obtain the necessary training. There is a great need for graduate nurses who may qualify as midwives to work in conjunction with the medical pro-

fession in the care of a large group of women who are unable to pay for adequate obstetric service under existing conditions.

1930 to 1939

James C. Masson spoke on "The Trend of Present-day Medical Education," stating that it is toward scientific medicine and specialization, which is not altogether due to the desire on part of physicians but is a natural reaction to demand made by the public. He said:

> It is difficult to see a satisfactory solution of the problem of furnishing adequate medical care for all the people at a cost which they can pay, but in recent years investigations which may lead to a solution have been begun. We can await the outcome of these studies, which are in able hands. Our task, meanwhile, I think, should be to help general practitioners to acquire adequate experience in obstetrics and gynecology, and to provide for admittance to the rank of specialists in obstetrics and gynecology only those who at the same time have a sufficient basis in general medicine and sufficient expertness in one special branch to enable them to render adequate service.

In 1931, the Section's annual volume, *The Transactions of the Section on Obstetrics, Gynecology and Abdominal Surgery,* was discontinued. Speaking on "The Biologic Significance of the Female Reproductive Cycle," Emil Novak stated that gynecology's "early history is a record of brilliant achievement in the development of operative procedure, and a subsequent generation has added comparatively little to this branch of our work. . . . Pathology is still, and always will be, a sine qua non in the proper training of the gynecologist. During recent years the line of advance has again shifted, for certainly at the present time physiology must be recognized as the growing margin of our specialty." He acknowledged the help of the anatomists and physiologists. In his discussion of periodicity in the female sex functions we find: "Periodicity may be said to be the rule of the universe." He recorded "some of the accomplishments and some remaining problems" and concluded with "the female sex cycle as distinguished from the female reproductive cycle." His closing paragraph expressed dependence on our allies in the laboratory, and he quoted from one of his papers: "So long as we recognize this dependence, and so long as we are willing to follow the line of scientific march rather than cavort ahead of it, we may perhaps be pardoned for an occasional display of overenthusiasm. After all, the latter is usually due to the fact that we have human beings to cure, just as the laboratory worker has scientific problems to solve."

Fred L. Adair, first president of the American Committee on Maternal Welfare (1934) and first president of the National Federation of Obstetric-Gynecologic Societies (1945), spoke on "The Interrelationship of Mother and Fetus" at the 1932 meeting. Included in his statements were these: "The exact relative importance of heredity and environment is not known." "We know that certain toxins will destroy germ cells. In all probability, they are subject to injurious influences which may not destroy their potency but which lead to subtle changes." He discussed "The Critical Early Period of Pregnancy," "Hormones," "Pathologic Conditions," and "Other Changes." His concluding sentence was, "These relationships are affected by the heredity of the parents, by the growth and development of the potential mother, by the character of the germ cells, by the maternal environment throughout pregnancy, by the critical period of parturition and, to a lesser degree, during the postpartum and postnatal periods."

Barton Cooke Hirst discussed "The Four Major Problems in Gynecology." He thought that "one of every eight women who reach the age of 35 will have cancer" and stated that there should be provision for both surgical and radium treatment. Concerning maternal mortality he said, ". . . half of these deaths are preventable." He considered "sterility" and "birth control." His address was somewhat philosophical and was terminated as follows: "In attempting to review so much in so short a time, I am aware that I give only the merest hints that may, perhaps, invite others to more productive thought, especially the younger members of the profession. We may confidently leave to them the problems vexing us. It is certain they will reach for higher levels of achievement than we have attained."

Joseph B. DeLee in his "Obstetrics Versus Midwifery" stated that contrary to the dictionaries he did not consider these terms synonymous; "midwifery is the practice of midwives, male or female, and obstetrics is the practice of the scientifically trained physician." He traced the historical development of midwifery and pointed out:

> . . . Until very recently the practice of normal obstetrics by physicians has been looked down on by the profession and by the public as well as by the midwives. . . . The public in many places still believes that his [the obstetrician's] accomplishments are less than those of the medical men and the surgeon. The medical schools, in many universities, still rate obstetrics as a minor specialty. . . . Hospitals do not provide equal facilities for obstetrics as for surgery. . . . All my medical life I have striven to eradicate this low opinion of obstetrics and to place on equally high pedestals the three primary branches of medicine, obstetrics, medicine and surgery, all equally important, all equally dignified.

He discussed "Disturbances of Pregnancy," "Labor," "A Natural Delivery," and "Attainment Through Education," bemoaning the fact that there were insufficient schools, teachers, material, and support. He believed in teaching the beauties of normal obstetrics, asepsis, intelligent expectancy, and trusting in nature.

James R. McCord, who was to be the first president of the South Atlantic Association of Obstetricians and Gynecologists three years later, was the 1935 Chairman. His presentation on "Syphilis and Pregnancy: A Clinical Study of 2,150 Cases," contained many statistical studies. His conclusions were as follows:

> 1. Pregnancy does not affect the reliability of the Wassermann reaction. 2. This test should be a routine part of antepartum care. 3. Regardless of the activity of the disease, sufficient antepartum antisyphilitic treatment assures the woman a syphilis-free baby in 95 per cent of the cases. 4. The best results will be obtained with ten or more treatments. 5. Treatment should be mild but continuous and should not be controlled by the Wassermann reaction. 6. The concurrent use of arsenic and a heavy metal has worked well in our hands. 7. Such therapy seems to be safe for the mother. 8. In the vast majority of cases, a strongly positive cord Wassermann test, properly done, means that the baby has congenital syphilis. A negative cord Wassermann reaction is of little value in the diagnosis of congenital syphilis. 9. The characteristic picture of osteochondritis of the long bones is pathognomonic of congenital syphilis. 10. There seems to be no condition in medicine that returns such huge dividends in life and health with such a small output of energy and money as that seen in the prevention of congenital syphilis.

In "Trends in American Obstetrics During the First Third of the Century," by Lyle G. McNeile, we find the opening sentence: "Although many notable advances and changes have been made in the practice of general medicine and surgery during the present century, in no specialty have there been more drastic changes than in obstetrics." He pointed out: ". . . at the beginning of this century every general practitioner had perforce to be an obstetrician; but at this time the new fledged doctor obtained his diploma to practice with little or no actual experience in clinical obstetrics. There were at this time not more than a half dozen medical schools that maintained lying-in hospitals in which medical students could witness deliveries, and the student who had actually delivered one or two women before he was graduated was considered very lucky." He discussed "The Dawn of New Obstetrics," "Causes That Contributed to the Changed Tendencies in Obstetrics," "Trends of the New Obstetrics," "Obstetric Education," "Is Pregnancy a Disease of Nine Months' Duration?," "Trend Toward Making Obstetrics Easier for Patient and Physician," "The Elimination of the Midwife," and "Apparent Trends Characterizing Obstetrics in Present Century."

Pierce Rucker discussed "The Treatment of Eclampsia," dividing it into two parts: preventive and curative. He strongly emphasized the former, stating that it should start when there is a rise in blood pressure or unusual gain in weight. Statistics on 129 treated cases were related under the headings "stopping the convulsions," "good nursing care," "promoting kidney function," and "digitalis," of which adequate dosage was deemed mandatory.

The Section on Obstetrics and Gynecology was the title used beginning in 1938. In "The Undergraduate Teaching of Obstetrics," E. D. Plass discussed factors relating to the problem and offered "a considerable defense of the men now actually engaged in obstetric teaching." It was pointed out that modern obstetrics is actually a field of preventive medicine. Didactic obstetric teaching was rated par with instruction in the other medical clinical branches, but it was emphasized that the clinical instruction could not be expected to result in competency to handle all obstetric emergencies. He pled for the more effective utilization of the trained and experienced obstetric specialists but appreciated the fact that changes in medical thought would inevitably be involved, requiring time.

Harvey B. Matthews directed attention to "Obstetric Shock: Its Causes, Recognition and Management." An historical account is given. The primary principles were elaborated. His concluding statement was as follows: "Real progress in the prevention, recognition and management of shock lies not only in cultivating the art of obstetrics but in the study of biologic principles that concern reproduction, function, nutrition, metabolism and the repair of tissues, and in the thoughtful application of this knowledge. With the mastery of these principles clinical experience and the maturity of years will give that degree of sound judgment which every physician doing obstetrics—general practitioner or specialist—longs to attain."

1940 to 1949

The 1940 address of Ludwig A. Emge, "Present Trends of Socialization of Medicine in Relation to Maternal Welfare," exemplifies intelligence and foresight, as time has proved. In a discussion of the aim of socialization, the national health program, the care of migratory workers in California, hospitalization, and the position of physicians in administration, the plea is made for enlightenment of the profession, the development of sound convictions, and "action—organization and cooperation —and this must come from within our ranks."

The following year Norman F. Miller discussed "The Perpetuation of Error in Obstetrics and Gynecology," listing the circumstances which "combine to make our time particularly susceptible in this respect" as the World War; "endocrinology, the beautiful romantic young maiden of modern medicine, who keeps us dizzy with her therapeutically provocative gyrations;" overzealousness in the field of medical writing; and blind adherence to obsolete ideas in our specialty. Careful consideration was given to "Errors That Are Being Perpetuated," "Perpetuation of Obsolete Standards," and "What to Do About It." He closed with this sentence: "If we recognize our responsibility and accept this challenge, if we are unafraid and willing to think and plan in terms of a newer and better standard of medical care for the pregnant woman, then I foresee for obstetrics, for maternal and child health, a new and great future."

The 1942 address, "The Educational Objectives of the American Board of Obstetrics and Gynecology," presented by Walter T. Dannreuther, president of the board since its founding 12 years prior, deserves to be read in its entirety.

The 1943 meeting was scheduled for San Francisco, but, because of war, only the Board of Trustees, Executive Committee, and the House of Delegates met. The next year, Louis E. Phaneuf's "The Changes in Operative Gynecology During the Last Quarter-Century" was summarized as follows:

> The last quarter of a century has shown significant improvement in surgical technic, with emphasis on careful dissection and ligation of individual vessels with fine material rather than mass ligature of tissues. The treatment of carcinoma of the cervix has changed from surgery to irradiation with the return to the radical pelvic operation by a few gynecologists in early cases and good surgical risks. Carcinoma of the uterine corpus and fundus has remained a surgical lesion, surgery, however, having been complemented by irradiation. Improvement in the operation of myomectomy has resulted in more conservative management of these lesions in the young; supravaginal hysterectomy still remains the common method in use, while an increasing number of gynecologists have turned to panhysterectomy as a prophylactic means against carcinoma of the cervical stump. Vaginal hysterectomy has been reborn and improved and has now become a commonplace procedure. The increased number of surgical vesicovaginal fistulas has been responsible for the elaboration of new technics in the cure of this lesion.
>
> Trachelorrhaphy and amputation of the cervix are less frequently done, these having been replaced in many cases by cauterization and electrocoagulation. A significant advance has been made in the surgical treatment of uterine prolapse, cystocele, and rectocele through better anatomic understanding of these lesions and by reconstructing the deficient supports through the vagina rather than by depending on abdominal suspension or fixation of the uterus. Pelvic inflammatory disease has been handled more and more by conservative methods, and the sulfonamide drugs seem to show great promise in lessening and eradicating this condition. Ovarian tumors have been better classified, the rare tumors have been discovered, the tendency of malignant changes in these neoplasms has been emphasized and their early ablation has been strongly advised.

The 1945 meeting was canceled due to war, and only the Board of Trustees, Executive Committee, and House of Delegates met. The next year, Philip F. Williams, to whom should go the highest of praise for his efforts in bringing into existence in 1951 the "national organization for ethical, competent obstetricians and gynecologists," spoke on "Maternal Welfare and the Negro." The reprint distribution of this address was considerable. His closing paragraph was as follows: "Obstetric care has undergone an evolution in this generation, but the Negro has not participated fully in the benefits of modern obstetrics. It is not possible to have two systems of maternal welfare; there must be one all-inclusive health program. Health education and adequate maternity care for the Negro are amply provided for in the proposed national health program of the American Medical Association. Conservation of human life in the process of reproduction should be shared equally by all Americans. The interest and activity of the medical profession can bring this about."

Alice F. Maxwell was in the Chair at the A. M. A. Centennial session of the Section. Her subject was "A Medical Inventory." Unfortunately, this address evidently was not published and a copy of the manuscript is not available.

William F. Mengert's "Estimation of Pelvic Capacity" included the listing of the five components of cephalopelvic disproportion as "size and shape of bony pelvis, size of fetal head, force exerted by the uterus, moldability of the head, and presentation and position." His discussion of subjects, methods, interpretation, and results and his comments are excellent and should be read in full.

1950 to 1957

"Reproduction in the Older Woman" was the title of the address by L. A. Calkins, and it included 10 tables of interesting data. In his summary and conclusions he stated:

> Older pregnant women, like other women of the same age but not pregnant, are more apt to have fibroids, hypertensive cardiovascular disease and, perhaps, carcinoma than are younger women. They are, therefore, deserving of the most careful and complete examination of all their organs and functions. The analysis also seemed to show that labor and the results thereof, except for a possible extremely moderate increase in fetal mortality, can be expected to progress along the same lines as for the younger groups. Our present fear of the outcome of pregnancy for the elderly primigravida is no more justified than would be such a fear for the elderly multigravida.

James Ramsdell Bloss, Chairman of the A. M. A. Board of Trustees in 1944, discussed "Causes of Fear Among Obstetric Patients" in his 1950 address, emphasizing that obstetricians and gynecologists must understand and "practice the humanities as well as the science of the medical profession." He included discussion of "Fears with Psychologic Basis," "Basic Conflicts," and "Fears with Legitimate Basis." It was pointed out that there has been too much disturbing publicity about the Rh factor. Frank, encouraging discussions with patients in the light of scientific medical accomplishments were recommended.

"The Test of Labor–An Evaluation of Its Present Worth," by Arthur B. Hunt, contained 10 tables. His conclusions were well drawn. They included this statement: ". . . to date there is no better way to justify an initial cesarean section than a failed test of labor." It also tests the obstetrician's "powers of observation, vigilance, judgment, obstetric conscience, and technical skill."

Louis H. Douglass spoke on "Repair of Obstetric Soft Tissue Damage Immediately Post Partum," based on an experience of about 17 years of practice, under the headings of "Cervical Repair at Delivery," "Perineorrhaphy at Delivery," and "Advantages of Elective Perineorrhaphy." He had been pleased with his anatomic results, and the expressions of gratitude from patients had been very rewarding.

Albert W. Holman was elected to the chairmanship for the 1953 meeting, but he died in 1952, being succeeded by Vice-chairman R. Gordon Douglas.

"The Challenge of Dystocia" was the subject of Chairman Bernard J. Hanley. His second paragraph began, "Prolonged labor per se is not necessarily harmful, but prolonged labor accompanied by a difficult forceps operation is a combination that always causes injury to the mother and is frequently lethal to the baby." He emphasized that patients in prolonged labor should be properly sedated and given adequate fluids. He and his co-workers had obtained excellent results in determination of the anterior pelvic depth by the use of the Hanley-McDermott pelvimeter, which he considered a rational procedure for determining the possibility of midpelvic or outlet dystocia.

Frederick H. Falls spoke on "Conquest of Eclampsia." A résumé of this is as follows:

> The convulsive stage of eclamptogenic toxemia has been gradually eliminated in three hospitals over a period of 20 years, despite the fact that eclampsia remains one of the three most common causes of maternal mortality in the country as a whole. The improvement is related to the increasing frequency with which toxemia is recognized and the systematic attention given to it. The mild nonconvulsive forms of toxemia, found and treated early, are without much danger. It is the convulsive stage of the disease that does irreversible or fatal damage. A simple program of management that has been developed must be brought to bear as soon as toxic symptoms appear and must be continued until the symptoms are brought under control or the patient is delivered. The program includes strict prenatal care, hospitalization if ambulatory care proves insufficient, induction of labor if the toxemia progresses, and cesarean section if certain indications exist. Although more knowledge of this disease is needed, the means for preventing most of the deaths that now occur are already available.

In 1956 Frank R. Lock discussed "A Concept of Operative Gynecology," which he summarized as follows:

> Operative gynecology is a major field of medical practice. Although the pathological significance and natural history of pelvic lesions is well known, the methods of management by the profession at large are variable. The arbitrary application of surgical procedures, according to the basic principles of the removal of pathology or correction of anatomical defects, is not acceptable in the field of gynecology. The effects of a given operative procedure must be weighed against the consequences of other management of existing pelvic pathology. It is possible to establish beyond a reasonable doubt that relief of symptoms will result from operative or nonoperative treatment in gynecology, through exact diagnosis and appraisal of the related pathologic, physiologic, and psychologic processes of women.

In 1957 D. Frank Kaltreider gave an address on "Fetopelvic Grading of Breech Presentations." THE JOURNAL's summary follows:

> In the management of a breech presentation, three factors must be considered in order to decide between vaginal delivery and cesarean section. These are (1) pelvic size, (2) pelvic shape, and (3) estimated fetal weight. Pelvic size can be accurately measured by x-ray pelvimetry. Unless the infant is premature, vaginal delivery is contraindicated in flat pelves with an obstetric conjugate of less than 10 cm. Fetal weight is best estimated by having four or more examiners give an estimate without the knowledge of others and averaging the estimates. In addition to the above three factors, the behavior of the sacrum and consideration of uterine inertia must also be taken into account.

Comment

Conceived by its 12-year-old mother, the A. M. A., the Section was born at term in 1860, being given the name "The Section on Practical Medicine and Obstetrics." That appellation was subsequently changed as follows: 1867, Section on Practice of Medicine and Obstetrics; 1873, Section on Obstetrics and Diseases of Women and Children; 1880, Section on Obstetrics and Diseases of Women; 1911, Section on Obstetrics and Gynecology; 1912, Section on Obstetrics, Gynecology and Abdominal Surgery; and 1938, Section on Obstetrics and Gynecology. Prior to 1958, the Section had held 93 meetings in a total of 30 cities, including Atlantic City, N. J., Chicago, and San Francisco, ranking in that order of frequency. War caused cancellation of the 1861, 1862, 1863, 1943, and 1945 meetings. The life of the Section has at times been impassioned and troubled, as exemplified by the Civil War years and the proposal of an abolition amendment in 1888. It has had its hours of bitterness and its reports of tragedy, but these are greatly outweighed by its superb and glorious hours. Mindful of its accomplishments and thankful to the Great Physician for them, we look to the future with anticipation of continued progress and happiness.

4240 Magnolia St. at General Pershing (15).

The bibliographic references have been omitted from THE JOURNAL and will be supplied by the author on request.

Data on the A. M. A. presidents were obtained from the section written by Walter L. Bierring, M.D., in "A History of the American Medical Association 1847 to 1947," by Morris Fishbein, M.D., published by W. B. Saunders Company, Philadelphia, 1947. That volume contains a paragraph on the Section on Obstetrics and Gynecology.

I am grateful to the following persons for their assistance: Albert W. Beacham, M.D.; Johnson F. Hammond, M.D., of THE JOURNAL; Thomas G. Hull, Ph.D., Secretary of the A. M. A. Council on Scientific Assembly; Miss Mary Louise Marshall, librarian, Rudolph Matas Medical Library; Miss Sarah Young; and Mrs. Margaret S. Bidwell, of the *Journal of the Louisiana State Medical Society.*

ANTICOAGULANTS—A COOPERATIVE EFFORT

THE advent of heparin and bishydroxycoumarin (Dicumarol) in the late 1930's and early 1940's as useful drugs for the management of thromboembolic disorders started a chain of events that went far beyond their use as agents for the treatment of thrombophlebitis. Anticoagulants have become generally accepted in the management of long-term and short-term therapy of coronary artery disease and myocardial infarction [1] and for the prevention or amelioration of certain cerebrovascular diseases.[2] Their availability has opened new areas of investigation into the mechanism of blood coagulation. Their promising use in cerebrovascular disease has occasioned a new and more precise classification of cerebrovascular diseases because, in the words of a committee of the Advisory Council for the National Institute of Neurological Diseases and Blindness, Public Health Service, the practitioner now has available powerful drugs which alter the coagulability of the blood. Hence diagnosis now becomes imperative not only as a means of directing therapy but also for further scientific study.[3] A premium is now placed on diagnosis of cerebrovascular disease, for the days of fruitless therapeutic maneuvers may be past.

Public interest in these drugs is reflected by the news concerning the President's use of an anticoagulant and more recently by the direction of the Senate Appropriations Committee to the National Institute of Health to study the action and utilization of anticoagulant drugs as aids in the treatment of coronary and cardiovascular disease (strokes). The directive was backed by a 2-million-dollar appropriation (Senate Report No. 17191, 85th Congress, 2nd Session, p. 28).

No less important has been the development of new coumarin compounds that made the use of anticoagulants more practical than bishydroxycoumarin, the first of the synthetic anticoagulants. Unfortunately, no useful substitute for natural heparin has appeared. Several recent reports in THE JOURNAL on warfarin sodium are examples of progress in that direction.[4] Interestingly enough both drugs had their origin in the same laboratory at the University of Wisconsin. Of equal interest is the fact that these valuable additions to the drug armamentarium came from unfettered research or as Link, the discoverer of bishydroxycoumarin and of warfarin, put it: "I think the secret of their success (his students) is three-pronged: they never ceased to wonder; they kept on trying, and they were on a project toward doing mankind some good instead of trying to destroy it." In these words, the aim of American medical research can be summed up.

Useful modalities in science and medicine do not come in full bloom. They develop by slow stages and from devoted workers. A review of the progress of the past 20 years in a symposium honoring the late Dr. Jay McLean by those intimately involved has recently appeared.[5]

Dr. Irving S. Wright, one of the most active proponents of anticoagulant therapy, pointed up the diseases susceptible to control by anticoagulants: "Today, throughout the civilized world and on both sides of the iron curtain,[6] anticoagulating drugs are used in a steadily increasing number of conditions. They are under study in hundreds of institutions. It is estimated that over one million persons suffer from thrombosis or embolism in the United States each year. These conditions include idiopathic, postoperative and traumatic thrombophlebitis, myocardial infarction, rheumatic heart disease with embolization, thromboembolism in pregnancy, peripheral arterial thrombosis and certain selected examples of cerebral thrombosis and embolism. More than four hundred thousand persons die each year with thrombosis or embolism as the terminal event. For each of these conditions and for many others, anticoagulant therapy has been used and should be considered. For some the indications are well established, for others the final chapters have not been written."

The four speakers, Drs. Irving S. Wright of the New York Hospital, Charles H. Best of Toronto, Canada, Armand T. Quick of Marquette University, Milwaukee, and Karl Paul Link, each presented his part in this story, which has since captured the interest of legislators.

Thanks to Dr. Wright, the reader can see the part played by the Association through its then Council on Pharmacy and Chemistry in the early days of bishydroxycoumarin. Several of his early patients developed hemorrhagic complications which had not been noted by those who worked with the compound earlier. He reported this incident and thus prevented the premature release of the drug until fully adequate studies permitted the development of safe directions for use. Through the action of the Council, many tragedies were averted by this cautious step. Indeed, this step may have averted the possible rejection of the coumarin anticoagulants in these early trying days. The reasons need not be detailed further than to point out that adequate methods for clinically controlling the reversible hypoprothrombinemia had not been fully developed. Fortunately, time and experience have placed the control of the reversible hypoprothrombinemia in proper perspective and on sound ground.

The method most commonly used to regulate dosage of bishydroxycoumarin and other anticoagulants which stemmed from it is the one-stage method, developed by Dr. Armand J. Quick. The test is taken for granted today, but the recital of the steps to reach this goal were retraced by its discoverer. Without the test or its modifications the availability of clinically useful anticoagulants would have been delayed. The use of a prothrombin determination cannot, as yet, be divorced from the administration of anticoagulants. Both complement each other. Just as the drugs themselves led to newer understanding of blood coagulation and the use of drugs which alter it, the newer methods such as prothrombin consumption time, the partial prothrombin test, and the thromboplastin generation tests are outgrowths of the one-stage prothrombin time test.

While the coumarin compounds are commonly associated with the term anticoagulant, the fact that the isolation of heparin and its use in thrombophlebitis antedated bishydroxycoumarin as an anticoagulant drug is often overlooked.

Modern heparin is due largely to the efforts of the late Dr. Jay McLean, who became interested in it as a student at Johns Hopkins University. In the very personal account of McLean's involvement with heparin, Dr. Charles H. Best of Toronto traced an item of purely physiological interest to therapeutics. This effort was truly international, for with the availability of purified heparin, Dr. Gordon Murray of Toronto made clinical trials in 1935, followed by Drs. Eric Jorpes and C. Craaford of Stockholm. The early finding that certain types of clinical thrombosis could be prevented by treatment with heparin has been amply confirmed.

It was early recognized that heparin, while an effective agent for prevention of clinical thrombosis, had serious disadvantages. The supply was limited by virtue of a limited supply of starting material, lung tissue; because it was active only on intravenous use, its action was short and consequently highly expensive.

The meeting of purely physiological and clinical studies came about originally through a veterinary and agricultural problem. Link, of Wisconsin, in 1933 started out to develop a strain of sweet clover which would not impart the hemorrhagic disease noted earlier in cattle who were fed on silage made from sweet clover. How the goal turned from cattle to man was told by Link. But bishydroxycoumarin was only the beginning of a large number of synthetic derivatives related to the parent compound, for as Link, the chemist, forecast in 1944, "we might be at the beginning of things and not at the end in this field of study."[7] The clinician, E. V. Allen, who was among the first to use bishydroxycoumarin clinically echoed in 1946 a similar sentiment: "Advantageous as both heparin and Dicumarol are, use of them represents only the first steps in the direction of securing satisfactory anticoagulants for clinical use."[8]

In the years intervening between the isolation and synthesis of bishydroxycoumarin, Dr. Link and his students set themselves another goal—to obtain an anticoagulant compound which would have "most of the desirable features that can be expected from an anticoagulant that can be given via the oral route." Earlier the clinicians virtually snatched a "cow-poison" for a human drug, but accepting a compound with a high rodenticidal value as a human drug was not so readily done. Fortunately, an aborted suicide attempt with a rodenticide containing warfarin paved the way. An article in THE JOURNAL[9] detailed the recovery of a patient after ingestion of large amounts of warfarin. In due time, the Wisconsin group provided water-soluble warfarin sodium for clinical use. The appearance of a score of papers on this compound since its introduction in 1954 led Link, the last of the quartet, to state: "It is my firm belief that in time it [warfarin sodium] will replace Dicumarol on the basis of its performance over a wide variety of conditions and that other anticoagulants of the Dicumarol type [including the many made in the Wisconsin laboratories] will not be superior." This view by one who has been responsible for the original impetus in this field represents a standard for future anticoagulant compounds. Whatever the future may bring in this respect, the physician who uses anticoagulants will want to keep in mind the triad of Link for successful use of anticoagulants. Successful anticoagulant management calls for (1) clinical judgment, (2) proper prothrombin determinations, and (3) the ready availability of vitamin K. The current literature on anticoagulants indicates that this is being heeded.

Thus the clock has made a full turn. The isolation of heparin by McLean and its purification by the Toronto group, the turn of a hemorrhagic disease of cattle to a human drug, the development of new methods to study blood-coagulation processes, the establishment of the value of anticoagulants in the treatment of myocardial infarction and a host of other thromboembolic conditions, the initiation of studies to assess their value in prevention and amelioration of strokes, and a new classification of cerebrovascular disease occasioned by these findings represent an excellent example of synthesis of laboratory and clinical developments going hand in hand.

Here is a historical account of unfettered research by free men at their best who set out to do some good instead of trying to destroy life. Here is a story of the intertwining of isolated effort; all the strands of which are playing a significant role in the present and future control of atherosclerotic and thromboembolic disease. Clinicians and laymen alike will watch with interest a forecast recently made: "If these trends are corroborated [reduction of morbidity in coronary artery disease], long term anticoagulation is the first distinct preventive agent in arteriosclerotic disease."[10]

INCOME TAX GUIDE

Last year, on March 1, 1958, THE JOURNAL published a special edition entitled "1958 Federal Income Tax Guide for Physicians." Copies of this guide are still available on request to the A. M. A. Law Department, 535 N. Dearborn St., Chicago 10.

LONG DISTANCE TELEMETERING AND MONITORING

The development of lightweight radio equipment for artificial satellites to transmit back to the earth environmental information about space and planets may also assist physicians and physiologists to gather physiological data on human beings and animals while ambulant and with normal freedom of movement. The equipment need not be so rugged as to withstand the large accelerative forces of a rocket but can be sufficiently sturdy to resist damage of accidental falls and to function under the vigorous bodily movement of athletes and men and women at their regular work. The equipment could record data also on sedentary patients.

Miniature broadcasting equipment and its uses have been dealt with in an article by Beenken and Dunn.[1] They visualize transmitters of not more than 2 lb. (0.9 kg.) in weight that can be operated by persons without radio engineering experience and that are nondirectional, within the tolerance of Federal Communications Commission recommendations, and with battery life of at least 100 hours.

Beenken and Dunn mention a list of physiological functions that can be studied with reasonable accuracy, such as temperature, pulse pressure, exercising tests, and oxygen demand. The physician might study cardiac output potential and record electrocardiograms while his patients are working at their regular jobs, and he might observe physical and physiological effects on patient-executives at the conference table. In the event the transmitter is made smaller (and one has already been made small enough for a man to swallow), the physiological changes in athletes may be observed while they are participating in competitive sports. Undoubtedly much discussion will ensue if and when football coaches read meters of electronic instruments to determine whether a player is tired and at the point of exhaustion.

These are a few of the achievements to be realized in the near future by the cooperative efforts of physicians, physiologists, and engineers. Increased interest in medical electronics is exemplified further by such meetings as the Conference on Electrical Techniques in Medicine and Biology, held in Minneapolis after the recent A. M. A. Clinical Session, and the meeting in New York, March 23-26, of the Institute of Radio Engineers, which has scheduled papers dealing with the applications of electronic tools and instruments to physiological, diagnostic, and clinical procedures.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

Nine months ago the Chairman of the A. M. A. Board of Trustees, Dr. Leonard Larson, pledged our Association to a dedicated and continuing effort to improve the health care of the aged. He made this vow in testimony before members of the House Ways and Means Committee in Washington, D. C.

Has the A. M. A. kept Doctor Larson's promise? Has medicine taken specific action at the national and state levels on the aged problem?

The answer is an emphatic yes. For example, the A. M. A. House of Delegates took farsighted action when it approved a proposal calling for development of an effective voluntary health insurance or prepayment program for the group of persons over 65 years of age with modest resources or low family income. Within three months official groups of several states—West Virginia, New Jersey, California, Texas, Ohio, Michigan, Florida, Iowa, and others—moved decisively on the A. M. A. policy recommendation. In addition, 34 state medical societies will give the matter top priority at their annual meetings this spring.

What are some of the states actually doing? In West Virginia the Association's Committee on Blue Shield has recommended that physicians accept 50% of their normal fees for Blue Shield clients over 65 years of age who have an income not exceeding $3,000 per annum. New Jersey has approved the A. M. A. policy and urged the Medical-Surgical Plan of New Jersey (Blue Shield) "to prepare a contract offering coverage at reduced premiums to people over 65 with reduced income."

Your A. M. A. also is working closely with commercial insurance organizations to encourage the development of new insurance programs and expansion of existing lower-cost protection.

Policies already available include some guaranteed renewable contracts, "paid-up-at-65" policies, senior security contracts, and "65-plus" policies. To further strengthen and improve private insurance coverage for those over 65 years of age, the Health Insurance Association of America has asked its 265 member companies to make available (1) policies guaranteed renewable for life, (2) coverage to persons now over 65 years of age, (3) coverages that will continue after retirement, and (4) the inclusion in the group contract of the right to convert to an individual contract at end of employment.

Through medical societies and the insurance industry sound and inexpensive protection to persons in the senior citizen bracket is being broadened and improved faster than many thought possible only a few months ago. We are not, however, confining our efforts to the development of financing mechanisms only. Solution of financial problems relating to the health care of the aged also depends on reductions in the costs of services.

Your A.M.A. believes that there is an undeniable need for new and improved facilities tailored to the specific health requirements of older citizens. Therefore, we vigorously support a government-insured loan program of the FHA type for nongovernmental hospitals and nursing homes whether their ownership is of a nonprofit or proprietary nature. We also recommend changes in the Hill-Burton act to make it possible for states to put more money into nonprofit nursing homes.

These then are some of the forward steps taken by your Association, the state medical societies, and the health insurance industry to improve the health care of the aged. No one can deny that there has been solid progress; we cannot deny that there is still much to be done. However, medicine and the members of the health team are in positive, forward motion against problems that not long ago may have seemed insurmountable.

GUNNAR GUNDERSEN, M.D.
La Crosse, Wis.

MEDICAL NEWS

ALASKA

Annual Meeting Held in Juneau.—The Alaska State Medical Association held its 14th annual meeting March 19-21 in Juneau under the presidency of Dr. William M. Whitehead. The guest speakers were Drs. Edward Morgan, clinical assistant professor of medicine, University of Washington Medical School, Seattle; Raymond F. Peterson, division of pathology, Murray Clinic, Butte, Mont.; and Robert A. Pommerening, clinical assistant professor of dermatology, University of Washington Medical School, Seattle. Addresses were given by Acting Governor Hugh J. Wade and Mr. M. L. MacSpadden, Mayor of Juneau. A panel discussion on "Ulcerative Colitis and Irritable Bowel Syndrome," held March 20, was moderated by Dr. Morgan. A film, "Surgical Repairs of Facial Lacerations for Optimum Cosmetic Results," and exhibits were held. The banquet, the evening of March 20, was held at the Baranof Hotel. A ladies' program was also arranged.

CALIFORNIA

Radiologist Given Award.—The Gold Medal of the American College of Radiology has been awarded to Dr. Robert S. Stone, chairman, department of radiology, University of California School of Medicine, San Francisco. The Gold Medal is presented annually "for distinguished contributions to radiological medicine." Dr. Stone joined the university faculty in 1928 and became professor of radiology in 1938. From 1942 to 1946 he was associate project director for health at the Chicago Metallurgical Laboratory of the atomic bomb project. After the war he developed and now directs the Radiological Laboratory at U. C. Medical Center, where physical, chemical, biological, and clinical investigations are conducted with the 70-million-volt synchrotron.

Name Dr. Kretchmer Department Head.—Dr. Norman Kretchmer, associate professor of pediatrics at Cornell University Medical College, New York City, and associate attending physician at New York Hospital, will succeed Dr. Robert H. Alway as head of Stanford University's pediatrics department, effective July 1. Dr. Ruth T. Gross, associate professor, has been acting head of pediatrics for the past two years. Dr. Kretchmer spoke in San Francisco Feb. 24 before the Northern California Chapter of the American Academy of Pediatrics. Last year the academy presented him with the E. Meade Johnson award for distinguished pediatric research. Dr. Kretchmer has taught at the University of Minnesota, Minneapolis, and the State University of New York.

COLORADO

Biography of Florence Sabin to Aid Research.—The University of Colorado Press, in connection with the state's Rush to the Rockies centennial observance, is publishing "Florence Sabin: Colorado Woman of the Century," a 222-page book, written by Mrs. Elinor Bluemel, of Englewood. The book traces the life of Dr. Florence R. Sabin, world-famous medical researcher, teacher, and humanitarian, who died in 1953. It contains eight pages of photographs. All royalties from the sale of the book will go to the University of Colorado School of Medicine for research in cellular biology. A statue of Dr. Sabin was dedicated Feb. 26 in Statuary Hall in Washington, D. C. She is the first Coloradan to receive such an honor. Born in Central City, Dr. Sabin went East to become the first woman professor at Johns Hopkins University, Baltimore, and the first woman to be elected to a life membership in the National Academy of Sciences.

FLORIDA

Cardiovascular Seminar in St. Petersburg.—The annual Suncoast and Hillsborough County Cardiovascular Seminar will be held Friday and Saturday, April 3 and 4, at the Tides Hotel and Bath Club, Redington Beach, St. Petersburg. Programs will be presented from 10 a. m. to 5 p. m. each day. This seminar is sponsored jointly by the Suncoast Heart Association, St. Petersburg, and the Hillsborough County Heart Association, Tampa. Seven specialists in various phases of diagnosis, treatment, and surgery in the cardiovascular field will present papers and take part in panel discussions, including Dr. John W. Hurst, Emory University; Dr. John B. Hickam, University of Indiana; Dr. Haddow M. Keith, University of Toronto Medical School; and Dr. Herbert E. Warden, University of Minnesota, Minneapolis. Credit for attending the seminar will be given by the American Academy of General Practice and the sponsoring heart associations cordially invite all physicians to attend. Registration fee

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

is $5. For information, write the Hillsborough County Heart Association, 111 Zack St., Tampa 2, Fla.

IDAHO

Cancer Conference in Boise.—The first annual Idaho Cancer Conference of the American Cancer Society, Idaho Division, will be held in Boise April 10-11 at the Hotel Boise, with physicians, dentists, and nurses participating. Of the six sessions scheduled, the following will be for physicians only, with Dr. Frank W. Crowe, Portland, Ore., presiding:

Diagnosis and Treatment of Cancer of the Uterus, Dr. John A. Wall, Houston, Texas.
Current Problems with Cancer; Polyps of the Colon and Rectum, Dr. Joel W. Baker, Seattle.
Breast Cancer—Treatment, Dr. Frank E. Adair, New York City.
Question-Answer session.
Conclusion, Dr. Crowe.

For information write Dr. Crowe at 116 W. State St., Boise, Idaho.

LOUISIANA

Appoint Dr. Beaver to Professorship.—Paul C. Beaver, Ph.D., was appointed the William Vincent Professor of Tropical Diseases and Hygiene at Tulane University School of Medicine, New Orleans. Dr. Beaver, formerly professor of parasitology, was a member of the medical school faculty since 1945. He succeeds Ernest Carroll Faust, Ph.D., who has reached retirement age but continues as field coordinator of the Tulane consultant program with the seven medical schools of Colombia, South America.

Personal.—Dr. Charles E. Dunlap, chairman, department of pathology, Tulane University School of Medicine, New Orleans, was reelected to a new three-year term on the Board of Directors of the Oak Ridge Institute of Nuclear Studies, Oak Ridge, Tenn. The council of the institute at its annual meeting Oct. 21 also elected Fisk University, Nashville, as its 37th sponsoring university.——Dr. William W. Frye, dean and professor of tropical medicine, Louisiana State University School of Medicine, New Orleans, was appointed to the National Advisory Allergy and Infectious Diseases Council. Since 1946, Dr. Frye has been a special consultant in tropical medicine to the U. S. Public Health Service.

MASSACHUSETTS

Dr. Jailer to Lecture.—The Alpha Omicron chapter of the Phi Delta Epsilon Fraternity will hold its Aaron Brown lectureship series April 3 in the Boston University School of Medicine auditorium. The guest speaker will be Dr. Joseph W. Jailer, department of medicine, Columbia University College of Physicians and Surgeons, New York City. His subject is "Certain Aspects of Hyperadrenalism."

MICHIGAN

Establish Residents' Day for Obstetrics-Gynecology.—An annual "Residents' Day" was established by the department of obstetrics and gynecology at Wayne State University College of Medicine, and the first program was held Feb. 25. All residents in obstetrics and gynecology in Michigan are invited to attend these one-day sessions held at the Wayne County Medical Society auditorium. Dr. Clyde L. Randall, chairman of obstetrics and gynecology, University of Buffalo College of Medicine, was the dinner speaker Feb. 26. Dr. Randall spoke on the "Oophorectomy and the Consequences." During afternoon ward rounds at Receiving Hospital, there was a brief presentation on the "Current Treatment of Pelvic Inflammatory Disease."

Mortality in Child Birth.—The rate at which Michigan women die as a result of childbirth or pregnancy was reduced by 67% in the last 10 years, according to figures released by the Michigan Department of Health. In 1947, 11 Michigan mothers died for every 10,000 babies born alive. In 1957, the rate was 3.8. Provisional figures for the first nine months of 1958 indicate the rate for last year will be below the 1957 figure. To stress the importance of early prenatal care, classes for expectant parents are conducted in 34 Michigan counties. Dr. Charles A. Behney, maternal and child health consultant, Michigan State Health Department, said major causes of maternal deaths today are hemorrhage, toxemia, infection, anesthesia, and heart disease.

Support for Survival Proposition.—Dr. George Moore, regional medical officer, Office of Civil and Defense Mobilization, Battle Creek, announced that "Michigan voters should support Proposition 1 on the state ballot April 6 to assure the survival of the state's government in the event of nuclear attack. Proposition 1 simply modernizes our present Michigan laws so that governments at all levels can carry out their responsibilities to assure the continuity of civilian government . . . judicial, legislative and executive . . . and the continuation of civil law in the event of a nuclear attack. Under this law, the Legislature can provide succession in office, if incumbents are disabled by enemy attack, and can adopt such other measures at county and city levels as is deemed necessary to assure that individual liberties and civil rights of the people will be preserved and protected following an enemy attack upon this Nation. If the amendment is approved by the voters it also provides that elections shall always be called, as soon as possible, to fill any elective vacancies, in any offices, temporarily occupied, due to the incapacity of the lawful elected officials. In effect, the law prepares for continuation of civilian law and order to prevent martial or dictatorial law in time of nuclear war."

MISSOURI

Dr. Wood to Give Annual Lecture.—Dr. W. Barry Wood Jr., vice-president, Johns Hopkins Medical Institutions, Baltimore, will deliver the ninth annual Memorial Lecture at the Menorah Medical Center of Kansas City on Tuesday, May 12. The subject of his lecture will be "The Genesis of Fever." Dinner will be at 6:30 p. m. and the lecture at 8 p. m.

NEW MEXICO

Devote Annual Meeting to Space Medicine.—The annual meeting of the New Mexico Medical Society in Las Cruces, May 5-7, will be devoted exclusively to space medicine, Dr. James C. Sedgwick, president, has announced. A tour and demonstration will be held May 5 at Holloman Air Base, N. M., a few miles from Alamogordo, where the Air Force Missile Development Center, Air Research and Development Command of the U. S. Air Force is located. Sessions on May 6 and 7, held in Milton Hall at New Mexico State University, Albuquerque, will include discussions by guest speakers on research problems in space medicine. Physicians will witness the routine operation of missile testing and may see missiles fired. The following are scheduled to discuss the subjects listed:

Dr. W. Randolph Lovelace, II, Albuquerque, "Crew Selection for Space Flight"; Col. John Pickering, Randolph Air Force Base, San Antonio, Texas, "Radiation Problems in Space Medicine"; Col. John Paul Stapp, Wright Air Development Center, Ohio, "Accelerations in Space Flight"; Major Stanley C. White, Washington, D. C., "Cabin Ecology for Space Flight"; and Capt. George E. Ruff, Wright Air Development Center, Ohio, "Psychophysiology of Space Flight."

Also present will be Dr. F. J. L. Blasingame, Executive Vice-President of the American Medical Association. The Air Force requires that all who plan to go on the conducted tour must preregister by April 15 to be cleared through security. All who have a registration badge will be permitted to board the Air Force buses for the tour, including wives, exhibitors, and guests. The Air Force will not permit private automobiles or cameras. Mail advance registration, with registration fee of $10, to New Mexico Medical Society, 220 First National Bank, Albuquerque, N. M. Room reservation information will be mailed to those who forward registration.

NEW JERSEY

Orthopedic Seminar.—The orthopedic department of St. Joseph's Hospital, Paterson, will hold an orthopedic seminar designed only for residents in orthopedic surgery on Saturday, April 4. Residents who are being trained in New England, New York, New Jersey, Pennsylvania, Delaware, Maryland, and in the District of Columbia are cordially invited. There is no charge. Advance registration is requested. Please address all communications to Dr. R. R. Goldenberg, St. Joseph's Hospital, Paterson, N. J.

NEW YORK

Meeting on Tuberculosis and Health—The annual meeting of the New York Tuberculosis and Health Association, Inc., will be held April 8 at the Hotel Statler Hilton, New York City. Moderator for the scientific and sociologic session will be Dr. John H. McClement, visiting physician-in-charge, chest service Bellevue Hospital. Papers to be presented include:

Tuberculosis Among the Navajo: Research in Cross-Cultural Technologic Development in Health, Dr. Kurt W. Deuschle, Cornell University Medical College.

The Tuberculin Test: An Old Test with a New Look, Dr. Michael L. Furcolow, Kansas City Field Station, U. S. Public Health Service.

Some Observations on the Use of Drugs in the Prevention of Experimental Tuberculosis (Chemoprophylaxis), Dr. Leon H. Schmidt, Christ Hospital, Cincinnati.

At the luncheon session, Dr. Carl Muschenheim, president of the association, will speak, and Dr. Walsh McDermott, Livingston Farrand Professor of Public Health and Preventive Medicine, Cornell University Medical College, will present "The Community's Stake in Medical Research."

Institute on Medical Teaching.—The second Summer Institute on Medical Teaching, jointly sponsored by the University of Buffalo and the Association of American Medical Colleges, will be held in Buffalo June 9-18, 1959. Included in the presentations, demonstrations, and discussions led by University of Buffalo faculty from the schools of medicine, education, and arts and science will be such topics as the nature of learning; the nature of medical students and medical faculties; the philosophical background for higher education in the United States; the use of lecture and laboratory, ward exercise, and clinical conference, as well as less familiar methods of instruction; and the use of tests and other appraisal devices for measuring student performance in a medical school. Opportunity for consultation on individual instructional problems will also be provided. Attendance will be limited. Interested members of Medical School faculties in the United States and Canada may apply for registration or information by writing Dr. George E. Miller, associate professor of medicine, University of Buffalo School of Medicine, Buffalo 14, N. Y.

New York City

Dr. Wilson Wins Prize in Neurology.—Irwin B. Wilson, Ph.D., associate professor of biochemistry, Columbia University, was awarded the annual prize in neurology given by the Association for Research in Nervous and Mental Disease. The prize carries an award of $1,000. Dr. Wilson recently achieved national recognition for his success at designing PAM, antidote against the toxic effects of nerve gas and insecticides. The citation issued by the association commended Dr. Wilson for his antidote and for his "contribution toward man's understanding of the action of toxic gases on the nervous system."

Doctors' Symphony Gives Benefit Concert.—The Brooklyn Doctors' Symphony Orchestra, of which Maurice P. Yuppa, D.D.S., is president, presented a concert on Feb. 20 for the benefit of Student Nurses recruitment program of the Nurses Association of the Counties of Long Island. Physicians, dentists, nurses, and members of allied professions are invited to become members of the orchestra. Rehearsals are held at 8:30 p. m. at The Clara Barton Vocational High School, 901 Classon Ave., Brooklyn. For details contact Dr. Benjamin A. Rosenberg, 909 President St., Brooklyn 15 (Nevins 8-2370).

Vitamin Researcher Celebrates Seventy-Fifth Birthday.—Dr. Casimir Funk, pioneer in vitamin research, marked his 75th birthday Feb. 23. Dr. Funk was born in 1884 in Warsaw, Poland, son of a dermatologist. He received his Ph.D. in organic chemistry from the University of Berne. He then went to the Pasteur Institute in Paris to work with Gabriel Bertrand, reportedly the first professor of biochemistry. At the Lister Institute in London, in 1911, Dr. Funk isolated from rice polishings a substance that cured beriberi. Knowing this substance essential to life, he gave it the name "vitamine," later changed to vitamin. Shortly thereafter, he isolated crystalline nicotinic acid and other vitamin B components from extracts of yeast and rice polishings, and worked out the manner in which thiamine (vitamin B_1) is utilized by the body. In 1923, Dr. Funk was appointed by the Rockefeller Foundation to organize the department of biochemistry at the State School of Hygiene in Warsaw. Since 1947, Dr. Funk and his co-workers at the Funk Foundation for Medical Research, a nonprofit organization, have been engaged in basic research on problems of cancer, diabetes, peptic ulcer, and arthritis.

OREGON

University Gets Million-Dollar Gift.—The University of Oregon Medical School will share equally with Good Samaritan Hospital, Portland, in the proceeds of an estate valued at 2 million dollars, Dr. David W. E. Baird, dean, has announced. The money, from the estate of the late Arthur H. Devers, is mostly in stocks and bonds, with about $100,000 in cash and mortgages. According to the terms of the will, Dr. Baird said, half of the funds, upon the death of Mr. Devers' widow, were to be turned over to the Oregon State Board of Higher Education for the purpose of teaching the subjects of eye, ear, nose, and throat at the University of Oregon Medical School. Mr. Devers, a coffee roasting pioneer, died Sept. 15, 1944. Upon his death a certain number of specific bequests were made and the residue of the estate was held in trust until the death of his widow, Mrs. Anne E. Devers, recently.

PENNSYLVANIA

Plan New Hospital in Media.—Directors planning the new Riddle Memorial Hospital near Media announced the appointment of a Doctor's Advisory Committee, composed of physicians serving on the staffs of other hospitals and clinics in the Philadelphia area. Riddle Memorial will be built largely from funds bequeathed for this purpose by the late Samuel D. Riddle, race-horse owner. It will be built on a 72-acre plot left by Mr. Riddle on Baltimore Pike near Media, to serve the 75,000 people of Central Delaware County. Long range plans include the erection of a modern 150-bed hospital, expandable to 300 beds, a nurses home, doctors offices, and a geriatrics center for research and study in connection with the rapidly growing elderly section of the American population. Cost of the main building, planned to be started in 1960, will be about 5 million dollars.

Philadelphia

Open Laboratory of Cytology.—A symposium on cytology was held Feb. 27 at the Hahnemann Medical College to mark the opening of the new Laboratory of Cytology. The following five pathologists spoke at the symposium: Dr. Cyrus C. Erickson, professor of pathology, University of Tennessee, Memphis; Dr. Irene Koprowska, director, Hahnemann Cytology Laboratory; Dr. Peter A. Herbut, of Jefferson Medical College; Dr. Emerson Day, director, Strang Cancer Prevention Clinic of Memorial Hospital, New York City; and Dr. James W. Reagan, Western Reserve University School of Medicine, Cleveland. Under Dr. Koprowska's direction, the Cytology Laboratory is engaged in a four-fold program. The diagnostic service examines body fluids and secretions for cancer cells. The laboratory is one of about 30 in the country recognized as a teaching center to train pathologists and technicians, and is approved by the Board of Schools of Medical Technologists of the American Society of Clinical Pathologists. The laboratory has been conducting research concerned with chemically-induced cervical carcinoma of mice. In a program supported by the U. S. Public Health Service, it also participates in a cooperative pilot study of the American Cancer Society and the Veterans' Administration concerned with a simultaneous mass population screening by cytologic and radiologic methods for the early detection of cancer of the lung.

VIRGINIA

New Headquarters Building for State Society.—The Medical Society of Virginia recently held an open house in dedication of its new headquarters building at 4205 Dover Road, Richmond. In 1946 the society expanded its work with the employment of the late Mr. Henry S. Johnson as director of public relations and the need for more adequate work space for society executives was apparent. In 1951, a building was purchased at 1105 W. Franklin St., which became the society's official headquarters. Subsequently, a study committee with Dr. Guy W. Horsley, as chairman, recommended that a new headquarters building be erected. This action was approved by the council, the House of Delegates, and the membership at its annual convention in 1956. The maximum sum of $120,000 was appropriated for purchase of the land, erection of the building, and for equipment. A building committee appointed by President James Hagood began its work on Oct. 31, 1956. The present property was acquired from the Richmond Foundation. The new building was completed in September, 1958, and contains a reception area, committee meeting rooms, executive offices, a small kitchen, a conference room, offices where the *Virginia Medical Monthly* work is done, and, on the second floor, the office of the Virginia Academy of General Practice. The land for the building cost $21,000 and the building itself cost $80,000. The total cost including architect's fees, equipment, etc., was just under $116,000. An off-street parking area in front of the building can accommodate 200 cars.

The new headquarters building of the Medical Society of Virginia located in Richmond.

GENERAL

Fellowships in Audiology and Speech.—Opening of competition March 6 for two fellowships in audiology and speech at Northwestern University, Chicago, has been announced by the American Hearing Society, its member agency, the St. Paul Hearing Society, and the university. Winners of the awards, known as the Reine Humbird Myers Fellowships, will receive $3,000 a year for two years while participating in a graduate program in preparation for work in local hearing societies. The fellowships were established in 1957 through a bequest from the Myers Foundation of St. Paul, Minn. Information and applications may be obtained from Crayton Walker, executive director, American Hearing Society, 919 18th St., N. W., Washington 6, D. C. Closing date for returning completed applications to Mr. Walker is April 6.

Biennial Conference on Anesthesiology.—"The Heart and Anesthesia" is the theme for the sixth biennial Western Conference on Anesthesiology to be held April 1-4 at the Westward Ho Hotel, Phoenix, Ariz. The conference will open with an address by Dr. Daniel C. Moore, Seattle, president, American Society of Anethesiologists. The following panel discussions and moderators are planned:

Applications to Clinical Anesthesia, Dr. Stuart C. Cullen, San Francisco.
Practical Use of Monitory Devices—Which, When, How, To Whom?, Dr. Robert D. Dripps, Philadelphia.
The Unsolved Problems of Cardiac Surgery, Dr. Robert W. Virtue, Denver.

A motion picture, "Fluothane," will be shown each day. Entertainment will include tours, golf, swimming, horseback riding, and a ladies' program.

Meeting on Border Public Health.—The United States–Mexico Border Public Health Association will hold its 17th annual meeting in Brownsville-Matamoros, March 30-April 3. During the plenary sessions there will be discussions on the recent progress in public health both in the U. S. and in Mexico, the activities of joint health councils in border communities, the epidemiology and laboratory aspects of arthropod-borne encephalitides, the needs and resources for the training of public health personnel working along the border, the rabies problem in the border area, and the attenuated live poliovirus oral vaccine. Six sessions (maternal-child health, veterinary public health, venereal diseases, nursing, sanitation, and tuberculosis) will meet, some of them in joint meetings. Simultaneous interpretation services will be available in all plenary sessions. For information write the United States-Mexico Border Public Health Association, 243 U. S. Court House, El Paso, Texas.

Psychotherapy Meeting in San Francisco.—The fifth annual Western regional meeting of the American Group Psychotherapy Association will be held April 2-3 in San Francisco at the Sheraton-Palace Hotel. Advances the past year in group psychotherapy will be keynoted in a paper by Dr. Martin Grotjahn, of Beverly Hills, with Mr. S. R. Salvson, of New York City, editor of the *International Group Psychotherapy Journal*, as discussant. More than 17 symposiums, workshops, and general sessions will consider group counseling in a state prison, group therapy programs for family agencies, group psychotherapy for criminal offenders, family group therapy, therapeutic techniques in adolescents' groups, the transactional analysis, treatment of psychotic patients by group methods, and allied subjects. The meeting arrangements are in charge of Dr. Hymen S. Morgenstern, of San Francisco, and Dr. Max A. Sherman, of Beverly Hills, co-chairmen. For information, write Dr. Donald A. Shaskan, VA Mental Hygiene Clinic, 49 Fourth St., San Francisco 3.

Study of Hospital Admissions.—The reason more than 20 million Americans—about 12.5%—enter a hospital each year will be the subject of a study authorized by the executive committee of Health Information Foundation. It will be conducted jointly by the National Opinion Research Center of the University of Chicago and the foundation. A sample of admissions to hospitals in Massachusetts will be examined through the approval and cooperation of the Massachusetts Medical Society, the Massachusetts Hospital Association, and the Blue Cross–Blue Shield Plans in that state. The 2½-year study will attempt to ascertain the nonmedical factors and family situations which lead to hospital utilization as well as medical reasons given by physicians. The survey is one of a group of major studies of voluntary health insurance sponsored by the foundation. The foundation was organized in 1950 as a contribution by the drug, pharmaceutical, chemical, and allied industries to research and education in the social and economic aspects of medical care.

Centennial for Section on Obstetrics and Gynecology.—The Section on Obstetrics and Gynecology of the American Medical Association will commemorate the 100th anniversary of its founding at the A. M. A. meeting in Atlantic City, June 8-12. A special program is being arranged for this occasion, including a commemorative luncheon and an address by Mr. Andrew Claye, of Leeds, England, president of the Royal College of Obstetricians and Gynecologists of Great Britain. Also included are a panel discussion on "Pelvic Exenteration—Current Status" on June 10; a combined meeting June 11 of seven A. M. A. Sections (Pathology and Physiology, Pediatrics, Nervous and Mental Diseases, Anesthesiology, Diseases of Chest, General Practice, Obstetrics and Gynecology) considering "Childbirth—Progress in Management"; June 12, a joint meeting with the Section on Pathology and Physiology, including two panels, "Ovarian Tumors" and "Rh Disease." Hotel reservation forms for this meeting will appear in THE JOURNAL or can be obtained from A. M. A. headquarters, 535 N. Dearborn St., Chicago 10.

Conference on Municipal and Industrial Waste.—The eighth Southern Municipal and Industrial Waste Conference will be held April 2-3 at the University of North Carolina, Chapel Hill. These conferences, organized jointly by Duke University, North Carolina State College, and the University of North Carolina, are for the purpose of bringing together representatives of industry, municipalities, and governmental agencies responsible for developing policies relating to the preservation of water resources in the southeastern part of the U. S. The eighth conference will be devoted to techniques available in the treatment of municipal and industrial waste waters. General sessions will be devoted to "solids separation processes," "chemical and biological treatment," and "solids handling and disposal." Formal papers will be followed by prepared discussions and by an informal discussion. Registration fee is $15 and includes attendance at all sessions, a copy of the conference *Proceedings*, two luncheons, and the social hour and banquet. For information write the University of North Carolina School of Public Health, Department of Sanitary Engineering, Chapel Hill, N. C.

Meeting on Physical Medicine in New Haven.—The Eastern Section of the American Congress of Physical Medicine and Rehabilitation will meet April 18 at the Yale University School of Medicine, New Haven, Conn. The program includes the following:

Connective Tissue Massage, Dr. Morton Hoberman, New York City.
Stretching, Dr. Thomas F. Hines, New Haven.
Proprioceptive Facilitation, Dr. Herman Kabat, Providence, R. I.
First Publications in Physical Medicine, Dr. John F. Fulton, New Haven.
Comparative Values of Electrodiagnosis and Electromyography, Dr. W. T. Liberson, Chicago.
Skin Thermometry in the Diagnosis of Peripheral Vascular Diseases, Alfred Ebel, New York City.
Importance of Leg Length in Low Back Pain, Dr. Harold Lefkoe, Philadelphia.
The Third International Congress of Physical Medicine, Dr. Frank H. Krusen, Rochester, Minn.
Trends in Medical Education, Dr. Vernon S. Lippard, dean, Yale University School of Medicine.

Parts of the program will be chaired by Drs. Robert C. Darling, of New York City, and Ernst Fischer, of Richmond. For information write Dr. Sidney Lich, 360 Fountain St., New Haven 15, Conn., secretary.

General Practice Meeting in San Francisco.—The American Academy of General Practice will hold its 11th annual scientific assembly April 6-9 in San Francisco's Civic Auditorium. The scientific program will feature 28 physician-speakers. More than 100 scientific and 300 technical exhibits are planned. The Congress of Delegates will convene at 2 p. m., April 4, in the Fairmont Hotel. Opening ceremonies at 1 p. m., April 6, include a call to order by Dr.

Holland T. Jackson, Fort Worth, Texas, president of the academy. Dr. Walter H. Judd, U. S. Congressman from Minnesota, will speak on "Doctors in a Changing World." Other participants include Dr. Leroy E. Burney, surgeon general, U. S. Public Health Service, presenting "Public Health: Its Relation to the Practice of Medicine," and James H. Steele, D.V.M., U. S. Public Health Service, who will give "Animal Diseases Transmissible to Man." The president's reception is planned for the evening of April 8. A ladies' program is arranged, and postassembly plans include the Invitational Scientific Congress April 13-14 in Honolulu, Hawaii. For information write The American Academy of General Practice, Volker Boulevard at Brookside, Kansas City 12, Mo.

Pediatricians Meeting in San Francisco.—The American Academy of Pediatrics will hold its spring session at the Sheraton-Palace Hotel, San Francisco, April 13-15. The general sessions and exhibits will be held at the hotel, and afternoon clinics will be conducted in four of the pediatric departments in the Bay Area, April 15. A "Conference on Respiratory Problems of the Newborn" will be moderated by Dr. Moses Grossman, San Francisco, April 13. The following panel discussions and moderators are scheduled:

Inborn Errors of Metabolism, Dr. Ruth Gross, San Francisco.
Some Current Problems in Infectious Diseases, Dr. Henry B. Bruyn, San Francisco.
Problems in Growth and Development, Dr. Donald Pickering, Portland, Ore.
Abdominal Surgical Problems in Pediatrics, Dr. Edward B. Shaw, San Francisco.
Adolescence—The Pediatrician's Problem, Dr. Arthur Roth, Oakland.
Clinical Pediatric Allergy, Dr. John P. McGovern, Houston, Texas.

Entertainment includes the banquet April 14, 8 p. m. ($7.50), and a ladies' program. For information write the American Academy of Pediatrics, P. O. Box 1116, Evanston Ill., Dr. E. H. Christopherson, Executive Secretary.

Meeting on Sterility in Atlantic City.—The 15th annual meeting of the American Society for The Study of Sterility will be held at the Shelburne Hotel, Atlantic City, N. J., April 3-5. The secretary of the society is Dr. Herbert H. Thomas, 920 S. 19th St., Birmingham 5, Ala., and the president of the society for 1959 is Dr. Edward C. Reifenstein Jr., New Brunswick, N. J. On April 3 the Squibb prize paper from the 1958 annual meeting of the Pacific Coast Fertility Society, "The Endocrine Control of the Passage of Spermatozoa and of Ova Through the Female Genital Tract," will be given by Dr. Robert W. Noyes, department of obstetrics and gynecology, Stanford University School of Medicine, San Francisco. On April 5 Dr. Peter M. F. Bishop will give the Ayerst Lecture, "Cervical Mucus." Dr. Bishop is from the department of obstetrics and gynaecology, Postgraduate Medical School, Guy's Hospital, and Chelsea Hospital for Women, London, England. The presidential address, "Nolle Nodere," will be presented by Dr. Sheldon A. Payne, The Shelton Clinic, Los Angeles, and the Fred A. Simmons Memorial Address, "Experience, Experiment, and Error in Sterility," by Dr. Alan N. B. Grant, department of gynaecology, Women's Hospital, Sydney, Australia.

Neurology Meeting in Los Angeles.—The 11th annual meeting of the American Academy of Neurology will be held April 13-18 at the Statler-Hilton Hotel, Los Angeles, under the presidency of Dr. Francis M. Forster, Madison, Wis. Special courses will be conducted April 13-15. The S. Weir Mitchell Award Essay is scheduled for the morning session of April 16. Papers to be presented by foreign participants are as follows:

Some Features of the Pathogenesis of Myotonia, N. I. Grashchenkov, Moscow, U.S.S.R.
Electrophysiological Study of Cortical and Spinal Cord Lesions in Cats with Allergic Encephalomyelitis, Roger M. Morrell, Montreal, Quebec.
Injury to the Nervous Tissue Produced by Intracarotid Injection of Alcohol, J. Olszewski and B. Rozdilskyi, Saskatoon, Saskatchewan.
Electron Microscope Study on the Function of Astroglia in the Water Ion Metabolism of the CNS, H. M. Gerschenfeld, F. Wald, J. A. Zadunaisky, and E. De Robertis, Buenos Aires, Argentina.

A symposium on rhinencephalon the morning of April 17 will have Dr. Ray S. Snider, of Chicago, as chairman. A joint meeting of the sections of neurochemistry and neuropharmacology will be held. Eighty-six papers are scheduled for presentation at the scientific sessions, and over 70 papers will be read by title. Scientific, society, and commercial exhibits and demonstrations and movies are planned. For information write the American Academy of Neurology, 4307 E. 50th St., Minneapolis 17.

Fellowships for Study of Human Ecology.—A grant from the estate of Anne Parrish Titzell, professor of medicine (neurology), Cornell University Medical College, New York City, made possible the establishment of fellowships for those interested in the study of human ecology and its relation to health. An immediate purpose is to provide opportunities for study and investigation for men who plan to pursue academic careers. Three general areas are within the scope of the program: the investigation of the social and physical milieu in which men live, and the attempt to learn more about how specific aspects of this milieu affect health and behavior; the investigation of the interaction between men and their milieu, and of how a man's perception of his life situation influences his reaction to it; the investigation of the interaction between bodily processes and the highest integrative activities of the brain, and the relevance of this to specific disease syndromes. Dr. Lawrence E. Hinkle Jr. will be associated with Dr. Harold G. Wolff in the direction of the program. The staff includes representatives from internal medicine, psychiatry, neurology, psychology, sociology, and cultural anthropology. Fellows will have an opportunity to participate in field observations of groups drawn from the general population, to take part in the long-term observation and care of out-patients in a research facility especially designed for this purpose, and to make use of laboratory facilities for the study of behavior, and of processes relating to the functions of various organ systems. Three fellowship appointments will be made annually each for a term of two years. Applicants should have completed one or more years of postgraduate training in the fields of internal medicine, neurology, psychiatry, preventive medicine, or public health. The stipend allowed is $4,500 the first year, and $5,000 the second; an additional allowance of $500 per annum is made for each dependent. To make application, write to Dr. E. Hugh Luckey, Chairman of the Department of Medicine, New York Hospital-Cornell Medical Center, 525 E. 68th St., New York 21.

CANADA

Surgeons Meet in Montreal.—A sectional meeting of the American College of Surgeons will be held April 6-9 at the Queen Elizabeth Hotel, Montreal. More than 15 symposiums are planned, and the following panel discussions and moderators are scheduled:

Biliary Tract Surgery, Dr. Richard B. Cattell, Boston.
Discussion on Activities of the College, Dr. Paul R. Hawley, Chicago, director of the college.
Angioplastic Procedures in the Management of Peripheral Arterial Occlusive Disease, Dr. D. Emerick Szilagyi, Detroit.
Anesthesia for Surgery, Dr. Louis Lamoureux, Montreal.
Medicolegal Aspects of Trauma, Dr. Alexander P. Aitken, Boston.
Cardiovascular Surgery, Dr. David R. Murphy, Montreal.
Fractures of Neck of Femur, Dr. J. Gordon Petrie, Montreal.

Dr. L. G. Stevenson, dean, Faculty of Medicine, McGill University, will present an address at the dinner of the Montreal Ophthalmological Society, 7 p. m., April 6. A round-table conference on detachment of the retina will be moderated by Dr. Samuel T. Adams, Montreal, April 7. At the college dinner 7 p. m., April 8, with Dr. Newell W. Philpott, Montreal, president of the college, presiding, Mr. Hugh MacLennan, Montreal, will be the speaker. Section meetings, motion pictures, and exhibits are arranged.

LATIN AMERICA

Nutrition Institute Founded in Mexico City.—A new, autonomous National Institute of Nutrition, comprising the Hospital for Nutritional Diseases, the Directorate of National Nutrition, and a Division of Research and Training, was organized by the government of Mexico. To help support research in biochemistry and nutrition at the institute, the Rockefeller Foundation appropriated $90,000 for use over a three-year period. The Hospital for Nutritional Diseases, established in the early 1940's, has contributed to medical training and research and to hospital care in Mexico. The Directorate of National Nutrition is responsible for community and public health aspects of nutrition. Studies undertaken by the directorate are being supported by the Mexican Department of Health with assistance received under a cooperative agreement with the World Health Organization, the United Nations International Children's Emergency Fund, and the Food and Agriculture Organization. The chief unit of the Division of Research and Training is the department of biochemistry. A staff, headed by Dr. Guillermo Soberon, has been formed, and a two-year course leading to the National University of Mexico's master's degree has been started. Initially, the biochemical research will focus on three main topics: the development of better methods for determining nutritional status; the nutritional value of Mexican foods; and protein metabolism, including the utilization of proteins and amino acids in Mexican foods.

FOREIGN

Spain's "Oldest Doctor" Dies.—The San Antonio *Light* reported that Dr. Jose Amo Serrano, reportedly Spain's oldest doctor, died in Cordoba, Spain, Jan. 9. Dr. Serrano had remained active in his profession until he was 100.

British and Irish Surgeons Meet in London.—The annual meeting of the Association of Surgeons of Great Britain and Ireland will be held April 23-25 in London under the presidency of Prof. Sir James Paterson Ross with the following papers scheduled:

Acute Pancreatitis.
Clinical Diagnosis in Chronic Pancreatitis.
Chronic Pancreatitis.
Islet-cell Tumors of the Pancreas.
Genito-urinary Tuberculosis.
Bone Tuberculosis.
Tuberculous Lymphadenitis.

A Moynihan Lecture at the Royal College of Surgeons will follow an afternoon of films, April 24, on which evening will be held the annual dinner. The Honorary Secretary of the Association is Mr. Rodney Smith, 47 Lincoln's Inn Fields, London, W. C. 2.

British Association for Medical Education.—The Association for the Study of Medical Education in Great Britain, organized late in 1957 to serve as a forum for persons interested in the problems of medical education and as a clearinghouse for information on the field, will be assisted during its initial, developmental years by a grant of £10,000 (about $28,500) from the Rockefeller Foundation to the Royal College of Physicians, London. The major purposes of the association are to exchange information on medical education in Great Britain, organize meetings on relevant topics, maintain a bureau where information can be received, stored, and made available to those interested, and encourage, promote, or conduct research into matters concerned with medical education. It is free to initiate other activities which it decides will advance the interests of medical education. Almost all the licensing bodies and medical schools of Great Britain, as well as individual medical educators and practitioners, are members of the new association.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Oral.* Phoenix, April 5-10. Applications now on file. *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications is July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral.* For candidates in the Midwest. Chicago, April 15-18. Final date for filing application was Jan. 1. *Oral.* For candidates on the West Coast. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. *Examination in the Subspecialties. Gastroenterology.* Philadelphia, April 17-18. Final date for filing application was Feb. 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *I. Oral and Clinical.* Chicago, May 8-19. Formal notice of the exact time of each candidate's examination will be sent him in advance of the examination dates. Candidates who participated in the Part I examinations will be notified of their eligibility for the Part II examinations as soon as possible. Deadline for receipt of new and reopened application for the 1960 examinations is Aug. 1, 1959. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Oral.* Philadelphia, June 2-6; St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 19-21, 1960. The deadline for the receipt of application is Aug. 15, 1959. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application is April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Boston, April 16-19. Final date for filing application was Feb. 28. Sec., Dr. Edward B. Smith, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application was February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Preventive Medicine: *Public Health.* Minneapolis, Boston, Baltimore, Chapel Hill, North Carolina and New Orleans, April 9-11; Berkeley, Calif., April 23-25; Pittsburgh, April 16-18. *Occupational Medicine.* Chicago, April 24-26. *Aviation Medicine.* Los Angeles, April 24-26. Final date for filing all applications is March 16. Sec., Dr. Tom F. Whayne, 3438 Walnut St., Philadelphia 4.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application is March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: New Orleans, Mar. 16-17; Chicago, Oct. 19-20; New York, Dec. 14-15. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Examination.* Chicago, June 2-4. If needed a special examination will be offered at this time in Nuclear Medicine to diplomates in Radiology or Therapeutic Radiology. The deadline for filing applications is April 1. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. *Part II.* San Francisco, April 13-14; Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 1959. *Final date* for filing application is July 1. *Oral.* September. *Final date* for filing application is July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. Final date for filing application is Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

GOVERNMENT SERVICES

NAVY

Captain Schiff Honored.—Capt. Maurice Schiff, chief of the eye, ear, nose, and throat service at the U. S. Naval Hospital, Oakland, Calif., was selected as the 1959 recipient of the Harris P. Mosher Memorial award, an honor that comes in connection with his election to active fellowship in the American Laryngological, Rhinological, and Otological Society, Inc. The organization confers this honor each year on the candidate who submits the best thesis. "Juvenile Nasopharyngeal Angiofibroma" was the title of Captain Schiff's thesis. Dr. Schiff presented his paper at the annual meeting of the society in Hot Springs, Va., on March 12. The honor carries with it a Harris P. Mosher Memorial award certificate, the listing of the recipient's name on the scroll published each year in the annual program of the society, 100 complimentary copies of the prize thesis, and its submission for consideration for publication in a forthcoming issue of *Laryngoscope.*

PUBLIC HEALTH SERVICE

Research Training Program.—Seventeen countries of Central and South America and Australasia will participate in the Public Health Service's international research training program. The program, which was started a year ago, provides medical research training in the United States for scientists from abroad. With the 17 new participants (Argentina, Australia, Brazil, Ceylon, Chile, Columbia, El Salvador, India, Iran, Japan, Mexico, New Zealand, Pakistan, Peru, Philippine Islands, Thailand, and Uruguay), 30 countries are now participating in the program. A research fellowship review panel of scientists has been established in each country. Within each nation, candidates are nominated by its scientific panel, and final recommendations for the awards from the Public Health Service are made by a research fellowship board of the National Institutes of Health.

The chairman of the fellowship board is Dr. John R. Paul, professor of preventive medicine at Yale University, who, with Dr. Ronald E. Scantlebury of the National Institutes of Health, served as advisor to the participating countries in setting up their review panels and in entering the program. In 1958, through similar panels, applications resulting in 17 awards were received from Austria, Belgium, Denmark, England, Finland, France, Germany, Holland, Italy, Norway, Spain, Sweden, and Switzerland. The 17 research fellows are now doing research in medical centers in the United States. Each fellow holds a doctoral degree or its equivalent in one of the medical or related sciences and has demonstrated promise in research. All have a workable knowledge of English. The training of these scientists from other countries will strengthen medical research throughout the world and will give outstanding scientists a chance to share knowledge with kindred groups by conducting research in the United States. Under the program, the Public Health Service provides a basic annual stipend of $4,500, allowances for wives and children, and limited travel funds. Information about the program may be obtained from Dr. Ronald E. Scantlebury, Chief, Foreign Grants and Awards, Division of Research Grants of the National Institutes of Health, Bethesda 14, Md.

New Publications.—A monograph entitled "Morbidity from Cancer in the United States" (PHS publication no. 590) by Harold F. Dorn, chief, Biometrics Branch, Division of Research Services, National Institutes of Health, and Sidney J. Cutler, Head, Clinical Biometry Section, Biometrics Branch, National Cancer Institute, is now available. Part 1 which was published separately, in 1955, deals with variations in the incidence of cancer by age, sex, race, marital status, and geographic region. The current publication completes the 10-city analysis and combines the analysis contained in part 1 with that in part 2, which deals with intercity variation in cancer incidence, trends in cancer morbidity, the association of cancer incidence and income class, and stage of disease at diagnosis. The study represents a statistical analysis of thousands of cancer cases examined in 10 large population centers in the United States which were surveyed in 1937-1939 and resurveyed 10 years later. The areas studied were Atlanta, Ga., Birmingham, Ala., Dallas, Texas, New Orleans, San Francisco, Denver, Chicago, Detroit, Philadelphia, and Pittsburgh. The book can be had by writing to the Superintendent of Documents, Government Printing Office, Washington 25, D. C. The price is $1 per copy.

The new training manual entitled "The Industrial Environment—Its Evaluation and Control" (PHS publication no. 614) is a syllabus of the short courses offered for industrial hygiene engineers and chemists at the Occupational Health Field Headquarters of the PHS in Cincinnati, Ohio. It is devoted primarily to fundamental principles and methods used in the evaluation and control of the working environment. It incorporates comprehensive reference materials, lecture outlines covering such areas as sampling analysis and engineering control measures, and laboratory exercises used in the courses. It includes a special section dealing with specific occupational health problems and their solutions. It is offered for sale by the Superintendent of Documents, Government Printing Office, Washington 25, D. C., at $2.75 per copy.

DEATHS

Ackerman, Emma Malinda Ⓜ Sioux City, Iowa; Creighton University School of Medicine, Omaha, 1913; for many years associated with the Florence Crittenton Home; on the staffs of the Lutheran and Methodist hospitals; died Jan. 14, aged 73.

Baranco, Raymond M., Baton Rouge, La.; Meharry Medical College, Nashville, Tenn., 1912; veteran of World War I; medical director of the Southern University and Agricultural and Mechanical College; a past-president of the Louisiana Medical, Dental and Pharmaceutical Association; died in Our Lady of the Lake Hospital Dec. 19, aged 68.

Baskett, Edgar Drane Ⓜ Columbia, Mo.; Johns Hopkins University School of Medicine, Baltimore, 1919; specialist certified by the American Board of Internal Medicine; served on the faculty of the University of Missouri; formerly on the staff of the Veterans Administration Hospital in Poplar Bluff; died in Dadeville, Ala., Dec. 31, aged 67.

Bein, Philmour Murray Alexis Ⓜ Mansfield, Ohio; University of Pennsylvania School of Medicine, Philadelphia, 1932; interned at the Philadelphia General Hospital; served a residency at the Jewish Hospital in Cincinnati; veteran of World War II; specialist certified by the American Board of Surgery; fellow of the International College of Surgeons; member of the Industrial Medical association; plant physician of Westinghouse Electric Corporation and medical director of the Ingersoll-Humphreys Division, Borg Warner Corporation; associated with the People's and Madison hospitals, and the Mansfield General Hospital, where he died Jan. 9, aged 52.

Berman, Leo, Newton, Mass.; born in Brooklyn April 13, 1913; Universitat Bäsel Medizinische Fakultät, Switzerland, 1937; certified by the National Board of Medical Examiners; specialist certified by the American Board of Psychiatry and Neurology, Inc.; interned at the Lincoln Hospital in New York City; served a residency at the Bellevue Hospital in New York City, Butler Hospital in Providence, R. I., and the Boston State Hospital; member of the American Psychoanalytic Association and the American Psychiatric Association; on the faculty of Harvard Medical School in Boston, where he was on the staff of the Beth Israel Hospital; died Dec. 27, aged 45.

Bostwick, William Warren Ⓜ White Plains, N. Y.; Bellevue Hospital Medical College, New York City, 1894; veteran of World War I; died Jan. 11, aged 85.

Bradford, Stella Stevens Ⓜ Montclair, N. J.; Cornell University Medical College, New York City, 1902; member of the American Rheumatism Association; for many years associated with the Mountainside Hospital, where she was director of the physical medicine and rehabilitation department; died in New York City Jan. 20, aged 87.

Chilton, James C. Ⓜ Hannibal, Mo.; Beaumont Hospital Medical College, St. Louis, 1891; served as division surgeon and examiner for the Wabash Railroad and surgeon for the Chicago, Burlington and Quincy Railroad for many years; chief surgeon for the Universal Atlas Cement Company; associated with St. Elizabeth Hospital and the Levering Hospital, where he died Jan. 11, aged 92.

Collins, James Newton Ⓜ Indianapolis; Emory University School of Medicine, Atlanta, 1922; assistant professor of radiology, Indiana University School of Medicine; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, the Radiological Society of North America, and the American College of Radiology; past-secretary of the Indiana Roentgen Society; on the staffs of the St. Vincent's Hospital and the Methodist Hospital, where he died Jan. 3, aged 62.

Cooper, Harry Bryant, Mill Valley, Calif.; University Medical College of Kansas City, Mo., 1899; went to Hawaii in 1905 to attend to the medical needs of sugar plantation workers and remained in the islands for 50 years; served on Selective Service boards during World Wars I and II; died Jan. 16, aged 85.

Daly, William Harvey Jr. Ⓜ Killeen, Texas; University of Tennessee College of Medicine, Memphis, 1949; interned at Methodist Hospital in Memphis, Tenn.; formerly a resident at the Scott and White Hospital in Temple, Texas; served as vice-president of the Bell County Medical Society; associated with Burow Clinic and Hospital; died in the Scott and White Hospital in Temple Jan. 8, aged 33.

Deem, Hamlin Nichleson, Wheeling, W. Va.; Ohio Medical University, Columbus, 1901; veteran of World War I; died in the Veterans Administration Hospital, Pittsburgh, Jan. 14, aged 82.

Deruha, John, New Rochelle, N. Y.; Magyar Királyi Påzmány Petrus Tudományegyetem Orvosi Fakultasa, Budapest, Hungary, 1920; died in New York City Jan. 16, aged 65.

Ⓜ Indicates Member of the American Medical Association.

De Salvo, Francis, Wausaukee, Wis.; Chicago College of Medicine and Surgery, 1917; served as health officer of Wausaukee for many years and member of the school board; at one time health officer of Niagara; died Jan. 26, aged 67.

Dozier, Joseph Vincent, Premont, Texas; Baylor University College of Medicine, Dallas, 1911; veteran of World War I; died Jan. 6, aged 82.

Elles, Norma Bertha Ⓜ Kalamazoo, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1906; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the American Ophthalmological Society; served on the faculty of Baylor University College of Medicine in Houston, Texas, where she was on the staffs of the Hermann Hospital, Memorial Hospital, and the Jefferson Davis Hospital; died in Houston, Texas, Jan. 12, aged 74.

Fasser, Alexander Otto Ⓜ Fremont, Neb.; Yale University School of Medicine, New Haven, Conn., 1905; veteran of World War I; died Jan. 14, aged 79.

Fenimore, William Nolan Ⓜ Wilmington, Del.; Jefferson Medical College of Philadelphia, 1921; veteran of World Wars I and II; served as coroner's physician; died Jan. 5, aged 72.

Hayes, Edwin Patrick Ⓜ Eau Claire, Wis.; born in Richfield Sept. 24, 1886; Marquette University School of Medicine, Milwaukee, 1913; past-president of the Eau Claire County Medical Society and the Tenth District Medical Society; served overseas during World War I; member of the American College of Obstetricians and Gynecologists and the Wisconsin Society of Obstetricians and Gynecologists; one of the founders of the Eau Claire Clinic, which was organized in 1921; on the staffs of the Luther and Sacred Heart hospitals; for 13 years director of Associated Hospital Service, Inc.; past-president of the Eau Claire Rotary Club; died in the Sacred Heart Hospital Dec. 26, aged 72.

Holland, John Gill Ⓜ Lynchburg, Va.; University of Tennessee College of Medicine, Memphis, 1933; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; president-elect of the Lynchburg Academy of Medicine; veteran of World War II; on the staffs of the Virginia Baptist, Lynchburg and Memorial hospitals; died Dec. 24, aged 56.

Horn, Dora L., Winter Park, Fla.; Cleveland Homeopathic Medical College, 1906; died Dec. 19, aged 75.

Hubbard, Milton E. Ⓜ San Francisco; University of Illinois College of Medicine, Chicago, 1928; veteran of World War II; retired from the Veterans Administration Feb. 19, 1957; died Dec. 24, aged 65.

Hutner, Louis Ⓜ Jamaica, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York City, 1934; specialist certified by the American Board of Dermatology and Syphilology; on the staff of the Queens General Hospital, where he died Dec. 15, aged 57.

Johnson, William Alexander, Reidsville, N. C.; North Carolina Medical College, Charlotte, 1907; member of the Medical Society of the State of North Carolina; died in the Moses H. Cone Memorial Hospital, Greensboro, Dec. 5, aged 76.

Keever, Henry Floyd Ⓜ Auburndale, Mass.; Harvard Medical School, Boston, 1908; associated with the Newton-Wellesley Hospital, where he served as a trustee; trustee at Lasell Junior College; died Dec. 26, aged 84.

Kells, Paul Ⓜ Miami, Fla.; University of Virginia Department of Medicine, Charlottesville, 1930; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association; veteran of World War II; on the staffs of St. Francis Hospital in Miami Beach and Mercy and Jackson Memorial hospitals; died Dec. 29, aged 56.

Koehler, Malcolm Harvey, Newark, Ohio; Ohio Medical University, Columbus, 1900; served as county coroner; formerly a medical examiner for the Baltimore and Ohio Railroad; died Dec. 29, aged 84.

Krohn, Morris Jacob Ⓜ Denver; University Medical College of Kansas City, Mo., 1903; on the staffs of St. Joseph's Hospital and the General Rose Hospital, where he died Dec. 26, aged 80.

Lamb, Ray Floyd Ⓜ Casa Grande, Ariz.; Northwestern University Medical School, Chicago, 1947; member of the American Academy of General Practice; formerly an officer in the medical corps of U. S. Army Reserve; died Dec. 23, aged 36.

Landes, William Latimer Small Ⓜ York, Pa.; Jefferson Medical College of Philadelphia, 1916; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; veteran of World War I; an honorary member of the radiological staff of the York Hospital; on the board of directors of the Western National Bank; died Dec. 21, aged 67.

Lawn, Hugh Edward, Chicago; St. Louis College of Physicians and Surgeons, 1923; veteran of World War I; affiliated with the South Shore Hospital; died in the Veterans Administration Hospital in Hines, Ill., Dec. 22, aged 63.

Leighton, Adam Phillips Ⓜ Portland, Maine; born in Portland Jan. 23, 1887; Medical School of Maine, Portland, 1910; for many years member and secretary of the Maine Board of Registration of Medicine; past-president of the Maine Medical Association, Cumberland County Medical Society, and the New England Obstetrical and Gynecological Society; in 1945-1946 was president of the Federation of State Medical Boards, of which he was formerly vice-president; since 1948 a member of the National Board of Medical Examiners as a representative of the Federation, and a member of the executive committee; specialist certified by American Board of Obstetrics and Gynecology; fellow of the American Association of Obstetricians and Gynecologists and the International College of Surgeons; served as chairman of the Portland City Council and member of the Board of Alderman, and school board; veteran of World War I; in 1912 established the Dr. Leighton Private Maternity Hospital; associated with the Pownal (Vt.) State School, St. Andrews Hospital in Boothbay Harbor, Webber Hospital in Biddeford, Maine General Hospital, and the Maine Eye and Ear Infirmary, of which he was a trustee; died Dec. 26, aged 71.

McClosky, Ben Martin Ⓜ Tampa, Fla.; Ohio State University College of Medicine, Columbus, 1927; member of the American Academy of General Practice; served as city and county physician; veteran of World War II; died Dec. 10, aged 57.

McDavid, John Solomon Ⓜ Oak Park, Ill.; Northwestern University Medical School, Chicago, 1924; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; on the staffs of the Cook County and Children's Memorial hospitals in Chicago and the West Suburban Hospital, where he died Jan. 4, aged 60.

Mieczkowski, Stanislaus C., Worcester, Mass.; Maryland Medical College, Baltimore, 1912; formerly police surgeon; died in St. Anthony's Hospital, St. Petersburg, Fla., Dec. 23, aged 70.

Miller, Brownlow Bartley, Tabor, Iowa; University of Nebraska College of Medicine, Omaha, 1908; served on the staffs of the Mercy Hospital in Council Bluffs, and Bishop Clarkson Memorial Hospital in Omaha; died Dec. 22, aged 73.

Moore, Edwin Fletcher Ⓜ Cincinnati; Ohio–Miami Medical College of the University of Cincinnati, 1912; member of the American Academy of General Practice; on the staff of St. Francis Hospital; died Dec. 29, aged 69.

Moran, Michael David Ⓜ Farmington, N. M.; Washington University School of Medicine, St. Louis, 1917; veteran of World War I; died in Albuquerque, Dec. 19, aged 66.

Morrison, Whitelaw Reid, Oberlin, Ohio; Columbia University College of Physicians and Surgeons, New York City, 1914; for many years on the faculty of Oberlin College, where he was professor emeritus; at one time associated with the University of Cincinnati; for many years served as chairman of the Lorain County Health Board; taught for two years at a Chinese government school in Shanghai; joint author of "Normal and Elementary Physical Diagnosis"; died in the Allen Memorial Hospital Dec. 26, aged 72.

Motley, Robert William, Tulsa, Okla.; (licensed in Oklahoma in 1916); on the staff of the Moton Memorial Hospital, where he died Dec. 30, aged 77.

Munger, Louis P. Ⓜ Hart, Mich.; Hering Medical College, Chicago, 1895; founder of the Oceana Hospital, where he was a member of the executive board until 1956; for 12 years member of the city council; vice-president of the Oceana County Savings Bank; associated with the Oceana Canning Company of Shelby for many years, and was chairman of the board of directors; died Dec. 23, aged 85.

Myers, Thomas Ⓜ Huntington Park, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1914; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; formerly on the faculty of his alma mater and the College of Medical Evangelists in Loma Linda and Los Angeles; affiliated with Mission Hospital in Huntington Park, Los Angeles County General and the White Memorial hospitals in Los Angeles, and St. Francis Hospital in Lynwood, where he died Dec. 19, aged 67.

Nickerson, Anson LeRoy Ⓜ Kankakee, Ill.; Rush Medical College, Chicago, 1904; served as secretary of the Kankakee County Medical Society; past-president of the Kankakee County Tuberculosis Association, of which he secretary; veteran of World War I; on the staff of the Kankakee State Hospital; on the honorary staff of St. Mary's Hospital, where he died Dec. 25, aged 81.

Norviel, Herald Bernard Ⓜ Phillips, Wis.; University of Illinois College of Medicine, Chicago, 1920; past-president of the Price–Taylor Counties Medical Society; on the staff of Park Falls (Wis.) Hospital; died Dec. 7, aged 64.

Okrainetz, Clara Loewenherz Ⓜ New York City; Thüringische Landesuniversitat Medizinische Fakultät, Jena, Thuringia, Germany, 1925; specialist certified by the American Board or Radiology; member of the Radiological Society of North America and the American College of Radiology; associated with the Manhattan Eye and Ear Hospital and the Montefiore Hospital, where she died Dec. 25, aged 58.

Osheroff, Samuel A. Ⓜ San Diego, Calif.; University of Nebraska College of Medicine, Omaha, 1919; affiliated with Scripps Memorial Hospital in La Jolla; died Dec. 26, aged 70.

Paisley, Ralph Clifton, Loudonville, Ohio; Ohio State University College of Medicine, Columbus, 1930; veteran of World War II; died Dec. 24, aged 54.

Ransom, Charles Loren, Danville, Va.; born in Syracuse, N. Y., Feb. 1, 1920; Syracuse University College of Medicine, 1945; certified by the National Board of Medical Examiners; specialist certified by the American Board of Urology; vice-president of the Virginia Urologic Society; interned at St. Joseph Hospital in Syracuse, N. Y., and Johns Hopkins Hospital in Baltimore, where he served a residency in urology; served on the faculty of Johns Hopkins University School of Medicine in Baltimore and the State University of New York College of Medicine in Syracuse, N. Y.; on the faculty of the Bowman Gray School of Medicine of Wake Forest College in Winston-Salem, N. C., veteran of World War II; associated with the Danville Memorial and Winslow hospitals; died Dec. 14, aged 38.

Reed, William Wallace Ⓜ Topeka, Kan.; born in Mosinee, Wis., April 1, 1880; Kansas Medical College, Medical Department of Washburn College, Topeka, 1905; specialist certified by the American Board of Otolaryngology; served as president of the Shawnee County Medical Society; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served as state supervising ophthalmologist for the division of service for the blind of the Kansas State Board of Social Welfare; veteran of World War I; on the staffs of Stormont-Vail and St. Francis hospitals; died Dec. 22, aged 78.

Reynolds, Grover C. Ⓜ Brundidge, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1911; died Dec. 26, aged 74.

Rifici, Charles, Camden, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1929; served as physician for the Camden City Highway Department, physician for local board number 9 of Selective Service, city physician, and medical inspector of public schools; died in West Jersey Hospital Dec. 22, aged 56.

Riley, Philetus Holt Ⓜ Madison, N. J.; New York Medical College and Flower Hospital, New York City, 1937; certified by the National Board of Medical Examiners; on the staff of the Morristown Memorial Hospital, where he died Dec. 28, aged 53.

Scott, Kenneth Hazen Ⓜ Plainfield, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1942; veteran of World War II; on the staff of the Muhlenberg Hospital; died Dec. 25, aged 43.

Sher, David Daniel Ⓜ Miami Beach, Fla.; Boston University School of Medicine, 1934; certified by the National Board of Medical Examiners; veteran of World War II; formerly practiced in Marlboro, Mass., where he was on the staff of the Marlborough Hospital; died Dec. 12, aged 52.

Simons, Edwin J. Ⓜ Edina, Minn.; born in St. Paul June 23, 1896; University of Minnesota Medical School, Minneapolis, 1924; member of the American College of Chest Physicians; fellow of the American College of Physicians and International College of Surgeons; veteran of World War I; executive director of Minnesota Blue Shield (Minnesota Medical Services) and one of its founders; past-president of the Minnesota State Medical Association; a director of the Minnesota Public Health Association; received a distinguished alumni award in 1956 from the board of regents of the University of Minnesota; for many years practiced in Swanville, where he served as president of the First National Bank; served on the staff of St. Gabriel's Hospital in Little Falls; author of "Primary Carcinoma of the Lungs"; died Dec. 11, aged 62.

Slaney, Andrew F. Ⓜ Oconto, Wis.; Loyola University School of Medicine, Chicago, 1917; veteran of World War II; for many years city health officer; on the staff of the Oconto County and City Hospital, where he died Dec. 19, aged 66.

Stern, Robert Leo Ⓜ Beverly Hills, Calif.; Rush Medical College, Chicago, 1934; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; veteran of World War II; deputy chief, hospital section, Los Angeles County Civil Defense Commission; on the attending staff, Cedars of Lebanon Hospital; on the staff of the Mount Sinai Hospital; past-president of the Beverly Hills Branch of the Los Angeles County Medical Association; died Dec. 17, aged 50.

Stevens, William Leary Ⓜ Shiloh, N. C.; University College of Medicine, Richmond, 1912; past-president of the First District Medical Society; served as health officer of Camden County; for 17 years medical advisor for the local board Selective Service; died in the North Carolina Memorial Hospital, Chapel Hill, Dec. 23, aged 70.

Stratton-Michener, Sina, Drexel Hill, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1895; served on the staff of the Pennsylvania Hospital in Philadelphia; died in Yeadon Dec. 16, aged 94.

Strother, Rodolph, Oberlin, La.; Memphis (Tenn.) Hospital Medical College, 1903; died Dec. 25, aged 76.

Tamraz, John Moorhaj Ⓜ Colonel, U. S. Army, retired, Miami, Fla.; Columbia University College of Physicians and Surgeons, New York City, 1917; entered the regular Army in 1920; retired May 31, 1949; veteran of World War I; during World War II was chief surgeon in the China-Burma-India Theater and received the Legion of Merit for exceptionally meritorious conduct in the performance of outstanding service; fellow of the American College of Surgeons; died near Richmond, Ga., Dec. 8, aged 69.

Tan, Gilbert Wai Man, Sacramento, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1957; city schools physician; interned at the Sacramento County Hospital, where he served a residency, and where he died Dec. 5, aged 31.

Taylor, Jackson Phyromn Ⓜ Los Angeles; Meharry Medical College, Nashville, Tenn., 1922; on the staff of the Temple Hospital; treasurer of the Broadway Federal Savings and Loan Association; died Dec. 28, aged 61.

Townsend, Robert Glenn Ⓜ Grayson, Ky.; Tulane University of Louisiana School of Medicine, New Orleans, 1927; member of the American Academy of General Practice; for many years associated with the Stovall Memorial Hospital, where he died Dec. 20, aged 55.

Twohey, Joseph Thomas Ⓜ Chicago; Loyola University School of Medicine, Chicago, 1932; member of the American Academy of General Practice; on the staff of St. Anne's Hospital; veteran of World War II; died Dec. 27, aged 51.

Van Zant, William Emory, Mandeville, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1901; died in St. Tammany Parish Hospital, Covington, Dec. 19, aged 81.

Vastine, Mary Frances Ⓜ Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1934; associate professor of radiology at her alma mater; certified by the National Board of Medical Examiners; specialist certified by the American Board of Radiology and the American Board of Otolaryngology; member of the Radiological Society of North America and the American College of Radiology; on the staff of the Hospital of the Woman's Medical College of Pennsylvania; died Dec. 11, aged 52.

Wasson, Valentina Pavlovna Ⓜ New York City; L. R. C. P., London and M. R. C. S., England, 1928; author of "The Chosen Baby" and co-author of "Mushrooms, Russia and History," written in collaboration with her husband, R. Gordon Wasson; attending pediatrician at New York Infirmary; died Dec. 31, aged 57.

Webb, Carol Castor Ⓜ Pensacola, Fla.; born in Albany, Ohio, March 31, 1895; Ohio State University College of Medicine, Columbus, 1918; honorary fellow of the Southeastern Surgical Congress; fellow of the American College of Surgeons; past-president of the Escambia County Medical Society; past-vice-president of the Frisco Railroad Medical Association; became local and later division surgeon of the Frisco Railroad and at the time of his retirement after 25 years' service was one of its consulting surgeons; veteran of World War I; in 1934 elected a director of the First Bank and Trust Company and served up to the time of his retirement; on the honorary staff of the Sacred Heart, Baptist, and Escambia General hospitals; past-president of the Kiwanis Club; died Dec. 29, aged 63.

Weber, Robert Cecil, Muncie, Ind.; Indiana University School of Medicine, Indianapolis, 1942; staff physician at the Veterans Administration Hospital in Marion, where he died Nov. 30, aged 40.

Wentz, John Wesley Ⓜ Pataskala, Ohio; Starling-Ohio Medical College, Columbus, 1910; for many years president of the school board; served on the staffs of the St. Ann's, Mercy, and St. Anthony hospitals, and the Grant Hospital, where he died Dec. 31, aged 73.

White, William Allen Jr. Ⓜ Boston; Harvard Medical School, Boston, 1921; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; assistant professor of clinical surgery at the Boston university School of Medicine; member and president of the staff of the Boston City Hospital; on the staffs of Faulkner Hospital, and New England Hospital; died in Milton Dec. 28, aged 62.

Williams, John Franklin Ⓜ Marion, Va.; Medical College of Virginia, Richmond, 1942; on the staff of the Southwestern State Hospital; died in the Lee Memorial Hospital Dec. 25, aged 58.

Williams, Percy Herbert Ⓜ New York City; Columbia University College of Physicians and Surgeons, New York City, 1901; fellow of the American College of Surgeons; served overseas during World War I; for many years associated with the Lenox Hill and Lincoln hospitals; died Dec. 31, aged 83.

Willson, Harry Leigh Ⓜ Idaho Falls, Idaho; University of Pennsylvania School of Medicine, Philadelphia, 1914; past-president of the Idaho Falls District Medical Society; associated with the Idaho Falls Latter-Day Saints' Hospital and the Sacred Heart Hospital; served as president of the Idaho Falls Rotary Club; died Dec. 29, aged 69.

Wood, T. Kenneth, Williamsport, Pa.; Medico-Chirurgical College of Philadelphia, 1903; for many years practiced in Muncy, where he was one of the founders of the Muncy Valley Hospital, where for many years he was president; established the Muncy Historical Society and was its first president; served as editor of the society's historical journal, *Now and Then;* died Dec. 28, aged 81.

Wright, Harrison Garner Ⓜ Bellingham, Wash.; Johns Hopkins University School of Medicine, Baltimore, 1919; served as president of the King County Medical Society; first president of the King County Physicians Service; fellow of the American College of Surgeons; associated with St. Joseph's and St. Luke's hospitals; died Dec. 23, aged 68.

Yankoff, Peter Demetroff, Fort Smith, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1918; died Dec. 25, aged 74.

Young, Samuel Alexander Ⓜ Cleveland; Western Reserve University Medical Department, Cleveland, 1904; past-president of the Southeast Kiwanis Club; on the staff of St. Alexis Hospital, where he died Dec. 30, aged 79.

FOREIGN LETTERS

GERMANY

Federal Drug Act.—The draft of the Federal Drugs and Pharmaceutical Preparations Act was passed by the government of the Federal Republic of Germany. Although the manufacture of pharmaceutical products has increased steadily since the beginning of this century, German law has not provided for any official licensing of pharmaceutical manufacturers. There were also no legal provisions regarding the qualifications of a head of a pharmaceutical manufacturing plant, and no regulations prescribing equipment, working conditions, safety measures, or hygienic control of the workshops. There is, therefore, an urgent need for laws to safeguard the quality of pharmaceutical preparations and the manufacturing process. The new act bans the manufacture and sale of drugs which are injurious to health or which are spoilt or adulterated in any way. This ban also applies to drugs with misleading designations and drugs made up in a manner which may give rise to misinterpretation or misrepresentation. It also prescribes the labeling and description of pharmaceutical products; for example, the mode of application must be given and the active constituents must be stated, using the designations given in the German Pharmacopeia.

The same regulations apply equally to drugs of foreign manufacture. Any application for permission to manufacture pharmaceuticals will be turned down by the authorities concerned if the person in charge of the manufacturing plant is not suitably qualified. Permission will also not be granted if suitable rooms and equipment for the manufacture, testing, and storage of the products are not provided. The head of a pharmaceutical manufacturing plant must have completed his university training as a pharmacist, chemist, physician, dentist, or veterinarian, and must have had at least one year's practical experience in the manufacture of pharmaceuticals.

Special regulations govern the manufacture of serums and vaccines. The following data must be filed with the application for the registration of any products: qualitative and quantitative composition, fields of application with contraindications, form and mode of application, instructions for use, and results of pharmacological tests and trials if the components include substances whose effectiveness is as yet unknown. This registration merely serves to keep a check on the traffic in pharmaceutical products. The question of the actual need for any particular product is not considered; neither is its therapeutic efficacy tested. Judgment on the efficacy of and on the need for a certain product can only be passed after long and careful examination and thorough clinical trials. Such tests and trials by the government would lead to undue delays in registration which might not be in the interests of the patients or the manufacturer. Registration is to be refused if it is evident that the manufacture of the drug would violate the ban on spoilt or adulterated drugs, on drugs made up in a misleading manner, and on products not properly designated and described.

Kallikrein.—On the basis of his experiments on rats, M. M. Forell of Munich concluded that pancreatic kallikrein participates to a great extent in the digestive process. It is secreted with the pancreatic juice into the duodenum and either increases the absorption of foodstuffs by augmenting the blood supply of the intestinal vessels, or has a physiological effect due to its stimulating action on the intestinal contractions during digestion. It was also shown that the formation of kallikrein by the pancreas and the production of the other enzymes depend on the diet. A meat diet increased the formation both of ferments and of the circulatory hormone, while a diet rich in fat caused a reduction in ferments and production of the circulatory hormone. Reduced or absent urinary excretion of kallikrein followed blockage of the pancreatic ducts, but in diabetes produced by alloxan, despite extensive destruction of islet cells, the formation of kallikrein was undiminished. An incretory formation of kallikrein could not therefore be assumed.

In the urine of healthy persons kallikrein is present in an active form. Since patients with renal hypertension and adrenocortical hypofunction excrete little or no kallikrein, E. Werle and R. Vogel of Munich concluded that in these patients kallikrein would be excreted in the form of the pharmacologically ineffective kallikreinogen. By the action of trypsin on the urine they demonstrated that the urine of patients suffering from renal diseases contained kallikreinogen. The amount of kallikreinogen in the urine was always in direct proportion to the amount of protein. This indicated a passage of the renal barrier together with the plasma protein. The kallikrein released behaved chemically like pancreatic kallikrein: it was destroyed by boiling and inactivated by soy bean inhibitor and ovomucoid. Protein-free urines might,

The items in these letters are contributed by regular correspondents in the various foreign countries.

however, also contain kallikreinogen, as was demonstrated in patients with myeloid leukemia and diabetes. Kallikreinogen was not demonstrable in the urine of healthy persons.

F. Hollwich and A. Wethmar of Frankfort tested the influence of commercially prepared kallikrein on healthy retinal vessels by direct measurement in 80 persons with normal circulation. Kallikrein was administered in active form (20 to 40 units of Padutin), in depot form (40 to 100 units of Depot-Padutin), and in inactivated form in doses of 100 units. The inactivated form was a combination of Padutin with its natural inactivator and in this form it constitutes a depot that can be activated to 95% in the body by slight shifts in pH. After the intravenous injection of Padutin a measurable effect was observed in 15 to 30 minutes. The maximal effect was seen after 60 to 90 minutes; 20 units of Padutin increased the diameter of the arteries by about 8%, while with 40 units the increase was about 12%. The effect lasted three or four hours with the smaller dose and five or six hours with the larger dose. Corresponding to the protracted absorption of kallikrein from the Depot-Padutin, a dilatation of the retinal vessels occurred only after 45 to 60 minutes and maximal dilatation only after 3 hours. The duration of action with 40 units was 6 to 8 hours and with 100 units 10 to 13 hours. The lumen of arteries dilated by 9 and 11% respectively.

A dilatation of the vessels after three or four minutes of 14 to 21% lasting for about eight hours set in after slow intravenous injection of 100 units of inactivated kallikrein. This rapid and long-lasting effect was manifested by the fact that in the combination of Padutin and an inactivator about 5% of the substance was already present in active form, and that the remaining 95% was gradually activated. After intramuscular injection of inactivated kallikrein the effect set in after 30 to 45 minutes, but it was not inferior to the intravenous administration as regards duration and intensity. Comparative examinations with other vasoactive substances revealed that the effect of all forms of kallikrein application set in later, but (with equal or almost equally high maximum values) showed exceptionally long-lasting effects. This demonstration of the vasodilatory effect of kallikrein was in line with the numerous clinical observations on the therapeutic value of Padutin and Depot-Padutin as seen in circulatory disorders of the arteries of the retina due to spasm or thickening of the wall, in disturbed blood supply of the optic nerves, in senile macular degeneration, and in myopic macular degeneration.

The effect of kallikrein on the peripheral blood supply, which so far was almost exclusively tested on the vessels of the skin in man, was also examined on the musculature by G. Golenhofen and H. Hensel of Marburg. With their new methods, which permitted separate determination of the blood supply of the muscles and the skin, they observed that, through intravenous administration of 10 units of Padutin and 100 units of inactivated kallikrein, an increased blood supply of the muscles was effected in practically all patients. With Padutin this was sometimes about 100% and with inactivated kallikrein up to 200% of the values obtained when resting. An increased blood supply of the skin of the extremities was not seen with the two substances. Only the facial skin showed an increased blood supply and was reddened, with Padutin more than with inactivated kallikrein. The effect which in all cases subsided within a few minutes after a single injection was markedly longer with inactivated kallikrein than with Padutin. Measurement of blood pressure revealed a fall of the average pressure by about 15% for a maximum period of three minutes. At the same time the increase in the pulse rate was 40% on the average and lasted four or five minutes.

Intra-arterial recording of the blood pressure showed that the increased blood supply caused by Padutin was due to a genuine vasodilatation and not to an enhanced pressure-passive supply, but the rise in pulse rate must also be interpreted as a sign of an increased blood supply due to vasodilatation. The trials were carried out on 22 young, healthy persons in 111 single tests, and care was taken that the same room temperature was maintained in all tests and that the patients were in a relaxed position. As the drugs to be tested were slowly infused intravenously in physiological saline solution outside the field of vision of the persons, any possible psychic influencing factor was excluded. During the trial the blood supply of the muscles of the calves and forearm was recorded with the aid of a heat-conducting probe. The blood supply of the skin was measured with a heat-conducting measuring instrument on the ball of the thumb, the sole, or the cheeks.

INDIA

Adrenal Cortical Hypofunction and Amebiasis.—Kasliwal and Mathur (*Journal of the Indian Medical Association,* vol. 31, Dec. 16, 1958) observed that in some patients with chronic amebiasis such clinical features of chronic adrenal insufficiency as asthenia, hyperpigmentation of the skin and mucous membranes, hypotension, and loss of weight were present. They therefore performed tests to assess adrenal cortical function in such patients to find out whether they had adrenal cortical hypofunction. Nine patients with chronic amebiasis diagnosed clinically and by the presence of Entameba histolytica in the stools were thus studied. Cysts of E. histolytica were found in six, trophozoites in one, and two had cysts of both E. histolytica and Entameba coli. All of them had some clinical evidence of chronic adrenal cortical insufficiency such as hyperpigmentation and asthenia. Healthy adults on whom the same tests were made served as controls. The age of these patients varied between 17 and 45 years, and the duration of illness between three months and nine years. The systolic blood pressure ranged between 80 and 104 mm. Hg and the diastolic pressure between 58 and 70 mm. Hg.

All showed hyperpigmentation of the skin and four had hyperpigmentation of the skin and mucous membranes. Two had marked asthenia and four had anemia. Hypoproteinemia and edema were present in all. One patient had hypochlorhydria, another achlorhydria, and one who had a pain resembling duodenal ulcer showed isochlorhydria. Three patients had such mental symptoms as inability to concentrate, insomnia, and marked fatigability. Three had such symptoms of hypogonadism as loss of libido and impotence in men and amenorrhea in women. Low values for serum sodium were obtained in eight patients and high values for serum potassium were obtained in seven. Mild absolute eosinophilia was present in two patients four hours after injection of 0.3 ml. of epinephrine; the eosinophil count fell by more than 50% in three patients and the percentage reduction in the other six was between 28.5 and 40. The urinary 17-ketosteroids ranged between 4.4 and 11.4 mg. in 24 hours in men and 3.1 and 4.7 mg. in women. Seven had a low urinary excretion of 17-ketosteroids and in two it was within normal limits. All these patients improved clinically after antiamebic and symptomatic treatment without any specific therapy for adrenal insufficiency. The exact cause for such insufficiency is not known, but chronic stress imposed by the various manifestations of chronic amebiasis or associated liver damage may be responsible.

Conference on Occupational Health.—Guide lines for the development of the occupational health services in southeastern Asia, made necessary by the increased speed of industrialization, were laid down in the conclusions reached at a southeastern Asia conference in Calcutta. The conference, jointly sponsored by the World Health Organization and the International Labor Organization, recommended that occupational health services be paid for by the employers but the provision of community health services covering workers and their families should be a governmental responsibility. Until community health services are fully developed, occupational health services should provide a certain measure of preventive and curative service, the extent of this being determined by local needs and resources.

These services should cover nonoccupational as well as occupational diseases. Institutes of occupational health should be developed to provide service, research, training, and technical information. Use should also be made of professional organizations in the field of occupational health. The training of physicians in industrial medicine should be given to the medical undergraduate, the physician entering the industrial health field, and the physician desiring to specialize in this subject. The training of industrial nurses and other auxiliary personnel is urgently needed. Persons trained in first aid should be available in every industrial undertaking, and regular courses in first aid should be given by the industrial physician. In establishing occupational health services it is not possible to exclude either legislation or education. Teamwork is a prime necessity in dealing with occupational health problems.

Prostatic Hypertrophy.—B. B. Ohri and co-workers (*Journal of the Indian Medical Association,* vol. 31, Dec. 16, 1958) studied 100 consecutive cases of senile enlargement of the prostate. All were subjected to the Freyer's method of suprapubic prostatectomy. Most of them sought medical attention because of acute retention of urine and were first treated with an indwelling catheter. Those without retention or who had retention with overflow were not catheterized. The series was divided into those whose bladder infection was mild (23), moderate (54), and severe (23). All were given 500,000 units of penicillin and 1 Gm. of streptomycin except those with severe infection who received 2 nitrofurantoin tablets, three times a day for four days. Most of this group had infection with Proteus vulgaris and Pseudomonas aeruginosa. Of the whole series 73 had acute retention. Those with a blood urea above 50 mg. per 100 cc. or with severe infection were treated with an indwelling catheter. Those who had severe urethritis or gross infection of the bladder and those whose blood urea level remained high in spite of the indwelling catheter (26) were subjected to a two-stage operation; 42 suffered from malnutrition and poor general health. The time spent in draining their bladders by an indwelling catheter or suprapubic cystostomy was used to improve their general condition.

The wound after operation usually healed in about two weeks. A bougie (size 9 to 12) was passed through the urethra on the ninth postoperative day as a routine. This prevented the formation of strictures in all but one patient who had a stone in the bladder. All patients received antibiotics postoperatively and nitrofurantoin was given to those with severe infection with P. vulgaris or Ps. aeruginosa. On discharge 42 had mild infection and others were free of infection. Postoperative hemorrhage occurred in four and two of them died. Of the 26 who had a two-stage operation, 4 died, 2 of complications of blood transfusion. The average stay in hospital was 22.3 days. Vasectomy was not done routinely. Gross wound infection after operation occurred in five patients but was treated successfully with nitrofurantoin.

however, also contain kallikreinogen, as was demonstrated in patients with myeloid leukemia and diabetes. Kallikreinogen was not demonstrable in the urine of healthy persons.

F. Hollwich and A. Wethmar of Frankfort tested the influence of commercially prepared kallikrein on healthy retinal vessels by direct measurement in 80 persons with normal circulation. Kallikrein was administered in active form (20 to 40 units of Padutin), in depot form (40 to 100 units of Depot-Padutin), and in inactivated form in doses of 100 units. The inactivated form was a combination of Padutin with its natural inactivator and in this form it constitutes a depot that can be activated to 95% in the body by slight shifts in pH. After the intravenous injection of Padutin a measurable effect was observed in 15 to 30 minutes. The maximal effect was seen after 60 to 90 minutes; 20 units of Padutin increased the diameter of the arteries by about 8%, while with 40 units the increase was about 12%. The effect lasted three or four hours with the smaller dose and five or six hours with the larger dose. The training of physicians in industrial medicine should be given to the medical undergraduate, the physician entering the industrial health field, and the physician desiring to specialize in this subject. The training of industrial nurses and other auxiliary personnel is urgently needed. Persons trained in first aid should be available in every industrial undertaking, and regular courses in first aid should be given by the industrial physician. In establishing occupational health services it is not possible to exclude either legislation or education. Teamwork is a prime necessity in dealing with occupational health problems.

Prostatic Hypertrophy.—B. B. Ohri and co-workers (*Journal of the Indian Medical Association*, vol. 31, Dec. 16, 1958) studied 100 consecutive cases of senile enlargement of the prostate. All were subjected to the Freyer's method of suprapubic prostatectomy. Most of them sought medical attention because of acute retention of urine and were first treated with an indwelling catheter. Those without retention or who had retention with overflow were not catheterized. The series was divided into those whose bladder infection was mild (23), moderate (54), and severe (23). All were given 500,000 units of penicillin and 1 Gm. of streptomycin except those with severe infection who received 2 nitrofurantoin tablets, three times a day for four days. Most of this group had infection with Proteus vulgaris and Pseudomonas aeruginosa. Of the whole series 73 had acute retention. Those with a blood urea above 50 mg. per 100 cc. or with severe infection were treated with an indwelling catheter. Those who had severe urethritis or gross infection of the bladder and those whose blood urea level remained high in spite of the indwelling catheter (26) were subjected to a two-stage operation; 42 suffered from malnutrition and poor general health. The time spent in draining their bladders by an indwelling catheter or suprapubic cystostomy was used to improve their general condition.

The wound after operation usually healed in about two weeks. A bougie (size 9 to 12) was passed through the urethra on the ninth postoperative day as a routine. This prevented the formation of strictures in all but one patient who had a stone in the bladder. All patients received antibiotics postoperatively and nitrofurantoin was given to those with severe infection with P. vulgaris or Ps. aeruginosa. On discharge 42 had mild infection and others were free of infection. Postoperative hemorrhage occurred in four and two of them died. Of the 26 who had a two-stage operation, 4 died, 2 of complications of blood transfusion. The average stay in hospital was 22.3 days. Vasectomy was not done routinely. Gross wound infection after operation occurred in five patients but was treated successfully with nitrofurantoin.

Tuberculous Meningitis in Women.—K. R. Sathe (*Journal of the Association of Medical Women in India*, vol. 46, November, 1958) reported that tuberculous meningitis, mainly a disease of children, is seen more frequently in women than in men. In a series of 27 women with tuberculous meningitis the age of the patients ranged between 12 and 40 years. The antecedent tuberculous lesions were in the lungs in 9, the abdomen in 5, the spine in 3, and in the remaining 10 no antecedent tuberculous lesion could be detected. This may have been due to the fact that these patients were moribund on admission. In five the disease was associated with pregnancy and in nine it manifested itself in the postpartum period. For this reason pregnant women with known tuberculous lesions should be under constant supervision as the occurrence of tuberculous meningitis in them could be prevented by the early use of specific drugs. In this series 15 died. This high mortality was due to the late stage of the disease at the time of admission. Of those who survived seven had relapses. This emphasizes the need for prolonged and skillful after care.

All the patients showed the characteristic changes in the spinal fluid. Greater reliance was placed on the depression in the glucose content than on the chlorides in the diagnosis. Recovery was not considered complete till the glucose level returned to normal. Acid-fast bacilli could be demonstrated in only one patient. Streptomycin was given in doses of 1 Gm. twice a day in the beginning, followed by 1 Gm. daily for one to two months, combined with PAS and isoniazid. Streptomycin was given intrathecally in the early cases but this practice was discontinued because of the pain it caused and the tendency to favor complications. Cortisone was used in only one patient, due to its prohibitive cost.

Hepatic Coma.—B. B. Bhatia and co-workers (*Journal of the Indian Medical Association*, vol. 31, Nov. 16, 1958) found that the number of patients with hepatic coma treated in the last five years was much larger than that treated in the previous five years. During this period, however, a larger number of patients with hepatic cirrhosis and infectious hepatitis applied for admission, and the percentage of hepatic coma associated with these conditions remained the same (about 5% in those patients with cirrhosis of liver and 4% in those with infectious hepatitis). The incidence of hepatic coma in patients with infectious hepatitis was a little higher in this series than in those reported by observers in other countries. This may have been due to delayed treatment and lack of rest in the beginning of the illness which is common here. The authors' series consisted of 58 patients (42 men and 16 women, in 5 of whom the coma was precipitated by pregnancy).

The most common exciting cause of coma in this series was intestinal hemorrhage and the authors recommended that in any patient with cirrhosis of the liver, at the onset of mental symptoms, the stools and vomitus be examined carefully for blood. Other exciting causes were acute infection, administration of ammonium chloride and acetazolamide, high protein diet, and pregnancy. The administration of acetazolamide for the relief of ascites precipitated the onset of coma in two patients. In the group with infectious hepatitis the major precipitating cause was pregnancy. All five pregnant patients were in the third trimester. The occurrence of infectious hepatitis in this period should be regarded as a serious complication. In one patient coma followed physical exhaustion.

Superadded acute infection precipitated coma in all patients with cholangiohepatitis. Treatment therefore consisted in avoidance of physical exertion and prescribing a high-protein diet, ammonium chloride, acetazolamide, urea, meperidine, morphine, and barbiturates. The diet should consist mainly of carbohydrates and proteins. Acute infections and hemorrhagic tendencies should be controlled. Between 1,000 and 1,500 ml. of 25% dextrose solution should be given intravenously every day and one capsule of tetracycline should be given hourly by mouth or in nasal feedings. About 75 Gm. of glutamic acid was given daily but its value was doubtful. The authors do not advocate a completely fat-free diet. The ideal diet for the patient is high in carbohydrate, with average protein and fat content. ACTH and cortisone are probably useful when the coma has supervened on an infectious hepatitis.

Chlorpromazine for Mental Disease.—N. N. Chatterji (*Journal of the Indian Medical Association*, vol. 31, Dec. 1, 1958) treated with chlorpromazine 137 patients who had schizophrenia, 65 who had manic-depressive psychosis, 35 who had obsessions or compulsions, 32 who had hysteria, 25 who had paranoia, 16 who had involutional melancholia, 12 epileptics with mental symptoms, 8 who had an anxiety state, 4 who had dementia, 4 drug addicts, and 4 who had periodic depression. The age of these patients ranged between 15 and 45 years. The usual dosage was 200 mg. daily in divided doses. A Rauwolfia preparation containing lucin-H was also given to those with paranoia, paranoid schizophrenia, and manic excitement. The duration of treatment varied from three to six months. Most patients tolerated the drug well. Toxic symptoms met with in some were severe constipation, diarrhea, jaundice, cutaneous rashes, paralysis agitans-like symptoms, giant urticaria with serous discharge from all the body openings, and fever.

The differential blood count in patients with fever showed neutropenia, eosinophilia, and relative lymphocytosis while the total leukocyte count showed leukopenia. Those who received large doses for a long time suffered from lethargy, weakness, and fatigue. Patients with schizophrenia, manic-depressive psychosis, and involutional melancholia responded well to the drug. Among the schizophrenics the best results were obtained in those with the catatonic variety. The symptoms disappeared within three weeks, and there was no need to give them shock treatments. In paranoid schizophrenics, although no response was obtained with chlorpromazine alone, good results were seen when it was combined with lucin-H, some patients being completely cured and others being able to go back to their social and occupational life in spite of the persistence of minor delusions.

In the paranoiac group, nine were completely cured with this combination. Manic-depressive psychosis showed an excellent response to chlorpromazine. The response was better in the manic phase when it was used in combination with reserpine. The depressed phase of manic-depressive psychoses subsided quickly with chlorpromazine. Results were good in patients with involutional melancholia but not in those with senile dementia. The increased excitability after fits in epilepsy were controlled with chlorpromazine. Among the psychoneurotic group, good response was seen in some patients with hysteria (mutism, aphonia, and fits). Good results were seen in obsessional neurosis. In drug addiction, although none was cured, the withdrawal period was easier with the use of chlorpromazine. Good results were obtained in patients with anxiety neurosis.

UNITED KINGDOM

Hazards for Young Doctors.—The hazards and rewards of different professions were discussed before the Royal Commission on Doctors' and Dentists' Remuneration. British Medical Association representatives said the road before the future hospital consultant was longer and more uncertain than that for men of other callings. The young physician, having completed seven years' undergraduate training, must serve in a hospital for a year as a provisionally registered practitioner and for two years in the armed forces before he will be free to decide on the direction of his career. By then contemporaries in other walks of life would have advanced to a point from which definite career prospects were in sight. Although the training for all professions is longer now than it used to be Dr. S. Wand, chairman of the B. M. A. Council, reminded the Commission that young men in some other fields are able to earn money en route. Invited to compare the young physician and the young barrister Dr. D. P. Stevenson, the association's secretary, said that whether or not the young barrister succeeded was very much in his own hands, but the young doctor might be forced into another branch of the profession outside the hospital field not because he was incapable but because there were no vacancies.

Dr. Gregory Dead.—Dr. J. C. Gregory, chairman of the All-England Lawn Tennis Club, Wimbledon, and a former Davis Cup player, died in the dressing-room of the club on Jan. 10, just after he had finished a doubles match. He was 55 years of age and had been in practice for nearly 25 years. He first represented England in 1926 when, as a member of the Davis Cup team, he played against Spain and France. From 1949 to 1953 he was the non-playing captain of the British Davis Cup team. After giving up the captaincy of the British Davis Cup team Dr. Gregory became vice-chairman of the All-England Club, and was elected chairman in 1955.

Future of the Tuberculosis Service.—The changes which have taken place in the last few years in the field of tuberculosis are the subject of an editorial in the *British Medical Journal* of Jan. 31. Although many beds for pulmonary tuberculosis have been closed because of the more rapid turnover of patients, hospital work has not decreased proportionately. On the other hand, the work of chest clinics may have increased. Since more patients suffer from pulmonary diseases other than tuberculosis, the work is much less routine in character than formerly. Figures obtained from 18 chest clinics showed that in one winter month of 1958 only 22% of new patients were diagnosed as having respiratory tuberculosis while 30% had acute respiratory disease and 27% had chronic respiratory diseases other than tuberculosis.

The Joint Tuberculosis Council strongly endorsed the view that facilities for the management of tuberculosis should be widened to serve patients with other respiratory diseases. This has already been done in many areas. Chest clinics are well able to coordinate inpatient, outpatient, preventive, and social services in the interest of patients with chronic respiratory diseases. They are peculiarly well suited to handle the problems presented by chronic bronchitis and to diagnose and treat bronchial carcinoma.

Perineal Carriage of Staphylococci.—Dr. M. Ridley, lecturer in bacteriology, St. Thomas' Hospital, London (*British Medical Journal*, Jan. 31, 1959) said that the possibility that the perineal region might be a carrier site on which Staphylococcus pyogenes var. aureus could multiply had been suggested but no information was available on the proportion of the population who are perineal carriers, whether they can disperse the organisms into free air, or the relationship between nasal and perineal contamination or carriage. A survey of 50 men showed that

52% had no Staph. pyogenes var. aureus in the nose or on the skin, 26% had this organism in the nose, generally in large numbers, but that the perineal area yielded fewer than 30 colonies from the six sites (total of 300 sites) chosen for examination. A further 12% had much greater degrees of contamination of the perineal area and were heavy nasal carriers as well. The remaining 10% had an equal degree of contamination of the perineal area but no Staph. pyogenes var. aureus in the nose, or at most five colonies. Thus, sufficiently large numbers of Staph. pyogenes var. aureus can be isolated from the perineal area of 22% of men to class them as perineal carriers. Further investigations showed that this state may persist for months in about 14%, that it is not due to fecal contamination alone, that the organisms can multiply in or on the perineal skin, that they may be of a different bacteriophage type from those found in the nose or feces, and that they may be dispersed into free air when the subject exercises in a cubicle.

Cost of Running Hospitals.—The cost of maintaining a patient in a London teaching hospital has risen to an average of $93 a week. This is shown in returns for the year ended March 31, 1958, and published by the Ministry of Health. The comparable figure in provincial teaching hospitals was $90. In nonteaching hospitals of 1 to 50 beds it was $59 and in those of 101 to 300 beds, $66. The average weekly cost in other types of hospital was as follows: chronic disease hospital, $26.50; maternity, $65; mental illness, $18; mental deficiency, $17; tuberculosis, $47; and children's acute disease, $63. Comparisons must be made with caution because of changes in accounting methods introduced in April, 1957. The net inpatient cost per patient at different hospitals averaged as follows: London teaching, $217; provincial teaching, $147; nonteaching, 101 to 300 beds, $130; maternity, $101; children's acute disease, $133.

Reducing Hospital Infections.—The widespread use of antibiotics, lack of facilities for isolating infected patients, and shortage of staff were among the chief causes of hospital infections, according to the report of Lord Cohen's Committee on Staphylococcal Infections in Hospitals. Unfortunately, funds and equipment are not universally available to allow staffs to carry out all recommended precautions (*Lancet*, Jan. 24, 1959). Staphylococcic disease was a major hospital problem before the era of antibiotics. The miraculous effect on it of penicillin, in 1944, was followed within two or three years by the appearance of the first penicillin-resistant strains of staphylococci. Today the drug is useless for most hospital epidemics. The breeding of drug-resistant strains has tended to increase the virulence of the organism and consequently to produce more severe infections. The fact that these are all theoretically avoidable in epidemic form led to the suggestion that penicillin be voluntarily withheld for a trial period of two years.

Lord Cohen's committee suggested that antibiotics such as erythromycin be kept solely for the treatment of infections due to strains resistant to other antibiotics and, except in emergency, should be prescribed only by a senior staff member. Strict observance of aseptic methods, not the use of antibiotics, is now necessary for the elimination of this serious problem. The report recommends extensive regular sterilization of all bedding, ward curtains, and other hospital materials with the suggestion that cotton blankets are more suited to this than woolen ones. The isolation of patients and of staff infected with whitlows and other staphylococcic infections is of paramount importance.

Reply to Attacks on Medical Profession.—Having read a letter from Sir Walter F. Hannay in the *Daily Telegraph* in which he deplored the trade union attitude of the British Medical Association, Prof. Charles Wells replied by means of an open letter in the *Daily Telegraph* of Jan. 22. He emphasized that the B. M. A. has never advanced the idea that physicians should withdraw service from their patients. What the B. M. A. suggested was withdrawal from the National Health Service and the provision to patients of continued medical attention at their own expense, the less affected areas subsidizing the more severely affected areas pending solution of their differences with the Minister of Health. Most trade unions would regard this as major lunacy.

A Cheaper Health Service.—A cheaper alternative to the National Health Service is being worked out by the British Medical Association. It might save the country as much as $840,000,000. The annual cost of the Health Service now exceeds $1,960,000,000 per year. It increases yearly as prices, salaries, and wages rise. The Association's Amending Acts Committee has laid down a series of basic principles which should underlie the new plan. The first is a statement that the preservation of private practice is essential to the development of medicine in this country, and its extension would insure a saving in public funds. The new plan would be financed by the state, the patient, and insurance. Payment by the patient would give him a sense of responsibility. There would be free care for the medically indigent. At present family physicians are paid a fee of $2.52 a year for each patient on their lists up to a maximum of 3,500 with an addition of $1.68 for each patient between the numbers of 501 and 1,500, bringing the fee for these patients to $4.20. This method of payment would be discontinued. Doctors would be paid a fee for each service rendered.

Concerning the possibility of abuse Dr. A. V. Russell, chairman of the Amending Acts Committee, said that there was some over-attendance in the early days of the Australian service, but this had been stopped by the profession itself. The principle of payment on a tripartite basis would free the service from the risk of political interference and enable the responsibility for its administration to be vested in a body on which the three contributing parties could be represented. Other principles laid down by the committee were (1) freedom of the physician, under safeguards, to prescribe whatever medicines he thought best; (2) restoration of the personal patient-physician relationship; (3) academic and professional freedom; and (4) avoidance of operating the health service in watertight sectional compartments.

Before any scheme is finally approved the draft must be considered by several interested committees. Endorsement by the Association's annual representative meeting would be necessary before such a plan became Association policy. The extent to which the state, the patient, and insurance, respectively, would pay for the cheaper alternative to the NHS has not yet been worked out. The only certainty is that the patient would contribute more than he does today through National Insurance, but he would stand to gain as a taxpayer.

The British Medical Association.—The Council of the British Medical Association has been forced to review its balance sheet. It has found that the existing dues for each ordinary members of $17.60 per year is insufficient to balance the budget. The prewar rate was $5.90. The Council decided, against strong opposition, to recommend to the representative body in July that the dues for 1960 be raised to $26.45. The principal reasons for the increase are inflation, the increase in the cost of the production of the *British Medical Journal*, the additional cost of the annual clinical meeting, further developments in regional offices, and the cost of fighting the Association's battles. Some believe that such a large increase will induce some members not to renew their membership, or to deter others from joining. Some suggest a means test whereby doctors in some of the lower income groups would pay a reduced charge while those in the surtax group would be expected to pay more. Many members fail to appreciate what the Association has achieved for them in its efforts to improve the conditions of service.

Poliomyelitis Vaccination.—Of the 6,250,000 people aged 15 to 26 who become eligible in the autumn for vaccination against poliomyelitis only 250,000 have been injected, and 96,000 of these have received only one dose. Ministry of Health officials and local health officers are disappointed and puzzled by the lack of response. Special efforts, such as evening clinics and injections at place of work, have been made to reach these young people. Local health authorities are starting a renewed drive. More special clinics and sessions at places of work will be arranged, and posters will urge young people to take advantage of the scheme. The acceptance rate for children up to the age of 15 is mounting, but both it and the response from expectant mothers must be improved.

Lung Cancer and Tobacco.—The Feb. 7 issue of the *British Medical Journal* contains three articles on lung cancer and tobacco. One of these, by R. Doll and co-workers, shows a definite relationship between the death rate from lung cancer and the length of discarded cigarette butts. In spite of the well-known difficulties of international statistical comparisons they found a distinct relationship in 16 countries between the reported cigarette consumption in 1930 and deaths from lung cancer in the period 1952-1954. Striking exceptions were Japan and the United States, which had a relatively high cigarette consumption but a relatively low incidence of lung cancer. In the United States one explanation may lie in the larger cigarette butt that the smoker discards. A comparison of cigarette butts specially collected and measured in Britain with similar data recently reported from the United States gives an average length of 30.9 mm. in the latter country against 18.7 mm. in the former. Of the cigarette butts in the British sample 67% were less than 20 mm. in length, and only 2.5% were as long as 30 mm. In the American sample less than 10% were smoked down to 20 mm., and 50% were discarded with 30 mm. or more still unsmoked. Such a large national difference in habits might greatly influence the national exposure to any carcinogen in cigarette smoke.

An article by I. T. T. Higgins of the Pneumonoconiosis Research Unit of the Medical Research Council discussed the relationship between tobacco smoking, respiratory symptoms, and ventilatory capacity in a series of 734 men between the ages of 25 and 64 who were randomly selected from urban and rural populations. A questionnaire was used to record respiratory symptoms and smoking habits. A clear relationship between smoking and persistent cough and sputum was invariably found, and smokers also tended to record more chest illness, wheezing, breathlessness, and chronic bronchitis than nonsmokers. Nonsmokers had a higher mean maximum breathing capacity than smokers; the best estimate of the difference, allowing for the size of the various groups studied, being 9 liters a minute. There was, however, no significant downward trend with increasing tobacco consumption among the smokers.

CORRESPONDENCE

THERAPY IN THE ANEMIAS

To the Editor:—In the June 7, 1958, issue of The Journal, page 735, an article entitled "Current Status of Therapy in Anemias," by Lichtman, states that parenterally administered iron, for example, in the form of an iron-dextran complex (Imferon) in great excesses over a long period of time will produce "exogenous hemochromatosis." Since parenteral therapy with properly calculated dosage of iron-dextran complex should be discontinued when a hematological response has been obtained, as well as when this type of therapy fails or the patient eventually becomes anemic, iron-storage diseases, i. e., hemosiderosis or hemochromatosis, should not occur under these circumstances, because the possibility of iron overload is eliminated. The subject of iron-overload has been discussed in a textbook, "Iron in Clinical Medicine" (edited by Wallerstein and Mettier, Berkeley, University of California Press, 1958). The question of whether hemosiderosis progresses to hemochromatosis has been answered both affirmatively and negatively. Much of the difference of opinion is a result of the different clinicopathological criteria used in defining hemosiderosis, hemochromatosis, and cirrhosis. From the studies of Baggenstoss, Weir, Kark, and myself—based on autopsy data from 35 patients with primary hemochromatosis, 7 with secondary hemochromatosis, and 21 with hemosiderosis and data from 10 living patients (9 with primary hemochromatosis, and 1 with secondary hemochromatosis)—we were able to establish definite clinical and pathological criteria mandatory in defining these conditions.

The evidence that iron per se does not produce hemochromatosis is summarized as follows: 1. The administration of iron, intravenously, orally, or in the form of blood transfusions in human beings, causes transfusional hemosiderosis but not hemochromatosis. 2. The administration of iron, orally or parenterally or in combination with cirrhotogenic diets, over long periods to experimental animals produces only hemosiderosis. 3. The amount of iron administered to patients through blood transfusions does not correlate with the degree of cirrhosis or hepatic, myocardial, or pancreatic fibrosis. 4. Oral Fe^{59} absorption studies, serial liver biopsies, serum iron and iron-binding capacity determinations, and evaluation of genetic traits of patients with hemochromatosis differ from those with hemosiderosis, which is actually only a pathological condition.

ACROMIOCLAVICULAR SEPARATIONS AND DISCUSSIONS OF PAPERS

To the Editor:—The report on suspension cast for acromioclavicular separations and clavicular fractures, published in The Journal (169:672-675 [Feb. 14] 1959) and presented at the A. M. A. meeting in San Francisco last June, leaves much to be desired. The paper gives the impression that many patients have been treated this way and that the results were good. However, what we saw when the paper was given was most inconclusive. It appeared that the acromioclavicular joints were still separated in the cases shown and that the suspension cast gave no better results than did a posterior figure-of-eight support in bilateral clavicular fractures. It is unfortunate that the discussion of this paper was not also presented in The Journal. In it these points were clearly brought out and doubt was cast on the value of this method of treatment. Many papers published in various journals lose their value when the discussion at the time of presentation is not also reproduced. Frequently the discussion points up the good and bad points of the method presented and entirely changes one's concept of whether or not it is worthy of a trial.

F. B. I. ITEMS IN THE JOURNAL

To the Editor:—In The Journal (169:640 [Feb. 7] 1959) is a letter from Dr. Guttmacher, of Baltimore, in which he criticizes the occasional acts of cooperation of The Journal with the F. B. I. I hope that there will be a continuation of appropriate aid to our law enforcement officers. I am sure that most physicians in the United States feel the same way.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Malpractice: Breach of Warranty.—This was an action for damages against the defendant psychiatrist. From a summary judgment for the defendant in the trial court, the plaintiff appealed to the United States court of appeals for the District of Columbia.

Because of the plaintiff's condition, the defendant recommended the administration of a series of electric shock treatments. Prior to giving them, contended the plaintiff, the defendant advised that the treatments were "perfectly safe," and she said she submitted to the treatments in reliance on such assurance. When she regained consciousness after one of the treatments, the plaintiff found that she had a fractured left arm.

The defendant denied making the statement attributed to him by the plaintiff. In a deposition, however, he said that the plaintiff's fracture was caused by the convulsive seizure which ensued as a result of the electric shock treatment and that in his practice this had occurred on seven or eight other occasions.

Doubtless, said the court, a physician's statement that he would cure a disease could seldom if ever be regarded as a warranty. But that is not this case. The statement attributed to the defendant, that shock treatments are "perfectly safe," contains less of prediction and more of present fact. We think this statement, if the defendant made it and did not qualify it in any way, might properly be found to be a warranty.

The summary judgment in favor of the defendant was therefore reversed. *Johnston v. Rodis*, 251 F (2) 917 (1958).

Malpractice: Delay in Using Lipiodol Dye X-Ray Technique with Lipiodol.—This was an action for damages for pain and suffering caused by the alleged negligence of the defendant surgeon. From a judgment for the defendant, the plaintiff appealed to the court of appeals of Maryland.

The patient, deceased wife of the plaintiff, was suffering from an advanced stage of cancer of the descending colon when she was referred by her own physician to the defendant for surgery. He found that a large cancer in the upper part of the descending colon had gone through all three coats of the intestine and had become attached to the back. He felt that complete removal of the tumorous mass would afford the best chance of preventing the spread of the cancer and of survival of the patient. In spite of the difficulty he removed a large portion of the colon, together with the large tumor, all in one piece and then joined together the two remaining sections of the intestine. After the operation the patient continued to have a fever for six weeks for which a variety of treatments were used including drugs, blood transfusions, and drainage operations. After the second drainage operation consultants were called in to attempt to locate the continuing difficulty. The consultants concluded "that there was still a collection of pus somewhere in the abdominal cavity that required drainage." It was suggested that two types of x-rays be taken, chest x-rays to determine the level of the diaphragm, and instillation of lipiodol dye to determine whether or not there was a tract that led to a pus pocket. The suggestion of injecting the dye in the fistulous area was adopted, the tract where the pus had accumulated showed up clearly, and an effective drainage operation was performed.

The gravamen of the plaintiff's charge was that the defendant delayed unduly in the use of the dye technique to locate accurately the pus accumulations.

There is a presumption, said the court, that a doctor has performed his medical duties with the requisite care and skill. The burden of proof is on the plaintiff to show both a lack of the requisite skill or care on the part of the doctor and that such want of skill and care was a direct cause of the injury; and if proof of either of these elements is wanting the case is not a proper one for submission to the jury. The plaintiff's main difficulty was the lack of affirmative proof of negligence on the part of the defendant.

We think, concluded the court, that the plaintiff has failed to meet the burden of presenting evidence which would support a finding of negligence. Though it might be inferred that if he had used lipiodol dye sooner the patient would have fared better, we do not think that the plaintiff has produced proof that the defendant was guilty of negligence in failing to use it sooner and in seeking to locate and drain the pus pockets by other means. He was clearly successful in locating a pus pocket on his first drainage incision, and that fact alone seems to prevent an inference that a dye injection was a necessary means of discovering the location of pus. Nor do we think that there is any such common knowledge of the use and efficacy of the dye method as to warrant us in holding that the jury might find, without supporting expert testimony, that the surgeon was wanting in reasonable diligence, skill, and learning because he failed to use this dye test in addition to others at an earlier stage of postoperative care of the patient.

Accordingly the judgment of the trial court in favor of the defendant physician was affirmed. *Lane v. Calvert*, 138 A (2) 902 (Md., 1958).

MISCELLANY

FOREIGN MEDICAL GRADUATES

A PROGRESS REPORT

T. Stewart Hamilton, Hartford, Conn.

The number of graduates of foreign medical schools taking the examination of the Educational Council for Foreign Medical Graduates is increasing by almost geometric progression and will reach an expected peak in 1959. In March, 1958, 298 physicians wrote the first examination; 844 wrote the September, 1958, examination; and some 2,300 have applied for February, 1959. It is important that we assess the status and the potential of this program as we plan for the future.

The ECFMG was formally established in 1957, after preliminary discussion and planning over the previous decade.[1] Its primary objective was to promote opportunities in the United States for advanced studies in medicine, to the end that the level of medical care might be raised throughout the world. Its primary concern was to safeguard the health care and welfare of the American public; therefore, it sought to determine that foreign medical graduates participating in patient-care educational programs in the United States had reached a level of educational attainment comparable to that of graduates of medical schools in the United States and Canada. ECFMG is sponsored by the American Medical Association, American Hospital Association, Association of American Medical Colleges, and Federation of State Medical Boards of the United States. Its trustees, composed of representatives of the sponsoring organizations and the public, have developed and implemented a plan for evaluation of credentials and administration of a qualifying examination. At the same time they have sought and obtained funds from the Kellogg and Rockefeller Foundations to initiate the program and engaged Dr. Dean F. Smiley as the executive director.

In March, 1958, the first examination was given to 298 physicians in centers in the United States and Canada. These graduates of foreign medical schools had already had from 1 to more than 20 years' experience with medicine in the United States. Questions were taken from those tested and used by the National Board of Medical Examiners. The questions were selected as being least likely to confuse those whose command of English was somewhat limited. Of these 298 physicians only 151 (51%) attained a passing grade of 75 or higher,[2] a disappointing result.

At the American Hospital Association convention in September concern was expressed that the new examination would greatly reduce the numbers of interns coming to the United States. Concern was also expressed that agreement by the National Intern Matching Program to accept certified foreign medical graduates for matching along with graduates of United States and Canadian schools would further deplete the intern supply available to hospitals now relying on these men and women to fill their quotas. These questions were voiced both at the Council on Professional Practice Review Committee meeting on Aug. 17, 1958, and later before the House of Delegates. Although no formal action was taken, the record of these proceedings included the suggestion of one delegate that "(a) The American Hospital Association . . . take steps to defer if at all possible, the inclusion of foreign medical graduates into the intern matching program until the program has been further evaluated and (b) to examine and test the present mechanism in view of the high percentage of failures."[2]

This seemed to relieve the administrators' minds, at least for the moment, since a program on the subject of the foreign medical graduate held later in the convention attracted a relatively small audience and evoked few comments or criticisms. It seemed that most delegates, while worrying about the possible implications of the program for their own institutions, recognized the need for such a controlled plan.

The ECFMG Examinations Committee reviewed the results of the March examination with great care and, noting that many who took it complained of its length, recommended that the number of questions be reduced and the time for its completion be extended. The question of lowering the passing grade from 75 to 70 was discussed at length. Decision against such a step was made on the ground that if it were taken the ECFMG could no longer state that the certified physician had reached a level of educational attainment comparable with that of a graduate of a United States school.

Dr. John P. Hubbard toured the world for the ECFMG during the summer of 1958 and set up 27 examination stations in Central and South America and overseas. On Sept. 23, 1958, 844 graduates of foreign medical schools whose credentials had been studied and approved wrote the new examinations, 707 in the United States and Canada and 137 in foreign centers.[3] Of those writing in U. S. stations 52.4% passed, which indicates that changing the examinations to reduce the number of questions and extend the time for their completion had little if any effect, for 51% had passed the first examination. A new and serious problem arose when the scores of those writing the examination overseas were compared with those of United States examinees. This is demonstrated graphically in the chart. While those writing in the United States did

Director of the Hartford Hospital.

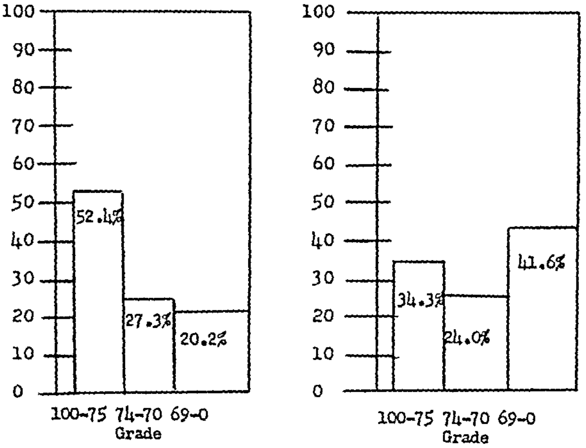
rather better than the March examinees, scarcely more than one-third of those writing in foreign stations attained a passing grade.

It was at once obvious to the Examinations Committee that to limit the number of certified foreign medical graduates from without the United States and Canada to barely more than one-third of those taking the examination would be serious indeed. It was obvious as well that, in comparing the results of the two groups, students benefited greatly from what they learned in the United States. For these reasons it was decided that a new category be established, called Temporary Certification. Temporary certificates, valid for two years' postgraduate training in the United States, will be given to examinees who attain scores of 70-75. By the end of the two years the graduate will be expected to have written and passed the certifying examination. The new category of Temporary Certification will entitle the holder to apply for any approved internship in the United States and to be matched through the National Intern Matching Program.

The decision to issue temporary certificates to those whose scores were within five percentage points of a passing grade was approved by the trustees as an expedient measure in the face of the unexpectedly poor showing of those who wrote the examination outside the United States. By its issue the percentage of examinees receiving either permanent or temporary certification was raised to 76.2. Of those writing in the United States 79.7% attained grades of 70 or higher while of those writing in foreign centers 58.3% attained such scores. Of the 844 who wrote the September examination 226 (26.7%) will receive temporary certificates. If they plan to take more than two years' postgraduate training in the United States it will be necessary for them to retake and pass the ECFMG examinations during that period. The two years is deemed necessary to give the graduate time to improve his knowledge, reapply, and rewrite the examination.

What of future examinations? As noted above, 2,300 graduates of foreign medical schools have applied to write in February, 1959; it is expected that at least an equal number will apply for the September, 1959, and February, 1960, examinations. After July 1, 1960, the date when all graduates holding internship and residency appointments will be expected to have qualified, the number of applicants should fall to between 2,000 and 3,000 per year. These will be graduates of foreign medical schools who are seeking appointments for the first time together with those holding temporary certification and others who apply to rewrite the examination. Examinations will be given as at present both in the United States and in foreign stations. Cost of the administration will be borne by both the applicants and the hospitals appointing them, the charge being $50 to the applicant and $75 to the hospital. Those eligible to apply will be graduates (and in some instances students in their last year) of schools listed in the World Health Organization World Directory of Medical Schools. Applications will be screened at the Council's headquarters, 1710 Orrington Ave., Evanston, Ill. Although actual scores and results of examinees by school or by nationality will be kept confidential lists of those certified will be made available to state medical boards and other authorized bodies.

While the program is scarcely under way and has had to face the usual problems of any new organization it already shows promise of the accomplishment of its twofold purpose: improving educational opportunities for graduates of foreign medical schools and insuring an adequate quality of care for patients. State boards of medical examiners in 16 states, for example, have already agreed to accept ECFMG permanent certificates as evidence for admission of a foreign-trained physician to their licensing examinations. It is expected that ECFMG permanent certificates will soon come to be regarded around the world as evidence that the holder has attained a level of medical competence equivalent to that of a graduate of a United States or Canadian school. In order to succeed the ECFMG will need the continued support of its sponsoring agencies and their membership. If it succeeds it can be a vital factor in the improvement of world medicine and world health.



Results of examinations taken by graduates of foreign medical schools at United States stations (*left*) and at foreign stations (*right*).

MEDICAL LITERATURE A

INTERNAL MEDICINE

Serum Triglycerides in Coronary Artery Disease. M. J. Albrink and E. B. Man. A. M. A. Arch. Int. Med. 103:4-8 (Jan.) 1959 [Chicago].

Lipids are transported in serum as constituents of 3 major classes of compounds: cholesterol and its esters, phospholipids, and triglycerides or neutral fat. Most investigations in recent years have centered about the notion that serum cholesterol plays a causative role in the development of coronary artery disease. Although triglycerides rather than cholesterol are chiefly responsible for turbidity of serum and constitute an important fraction of β-lipoproteins, the quantitative estimation of triglycerides has been largely neglected in studies of serum lipids in coronary artery disease. The present research was undertaken to observe the interrelation of the 3 major serum lipid fractions. The subjects were 100 patients with a history of myocardial infarction. The group included 82 men and 18 women, ranging in age from 21 to 78 years, the greatest number being in their 50's. Control subjects included healthy medical students, industrial workers, and hospital patients without vascular disease and without known metabolic disorders.

Elevations of serum triglycerides above 5.5 mEq. per liter (about 160 mg. per 100 cc.) occurred in only 5% of normal young adults, in at most 30% of normal men over 50, and, if the effects of acute illness were excluded, in 85 to 90% of patients with coronary artery disease. The authors believe that few, if any, other lipid measurements which have been reported effect such a clear-cut separation between normal and coronary subjects. The observations reported suggest that an error in the metabolism of triglycerides is the lipid abnormality operative in coronary artery disease. It may be that other findings commonly reported in this disease, such as increased cholesterol, increased low-density lipoproteins rich in triglycerides, and prolonged and intensified alimentary lipemia, are secondary to decreased efficiency of resulting accumulation It is tempting to speculate o these findings in relation to the e of the heart, particularly in the light dence that fat is an important source of normal myocardium, that triglycerides are over with great rapidity by heart tissue, and lipoprotein lipase occurs in high concentration in myocardial tissue.

The Post-Myocardial-Infarction Syndrome: A Report of 44 Cases. W. Dressler. A. M. A. Arch Int. Med. 102:28-42 (Jan.) 1959 [Chicago].

The author presents observations on 44 patients with recent myocardial infarction, whose clinical picture did not conform to the textbook pattern of myocardial infarction. There were prolonged and recurrent fever and chest pain. Relapses occurred frequently and caused prolongation of the clinical course by several weeks or months. Such features are usually attributed to recurrent myocardial or pulmonary infarction. However, in the patients studied, electrocardiographic signs of extension of myocardial infarction were absent, and there were no features indicative of phlebothrombosis in the lower extremities or obvious signs of pulmonary infarction. Instead, evidence of generalized pericarditis with effusion often associated with pleurisy and pneumonitis was observed. This triad, which closely resembles the postcommissurotomy syndrome and idiopathic pericarditis, has been referred to as the postmyocardial infarction syndrome. The 44 patients were observed at the Maimonides Hospital in Brooklyn, N. Y., in the course of the past 2 years.

Several illustrating case histories are presented, and the author discusses various aspects of the postmyocardial infarction syndrome. It differs from the common "pericarditis epistenocardica" by longer duration of fever and chest pain and by relapses of fever and pleuropericardial pain; the pericardial friction rub lasts longer or occurs later than usual; there is pericardial effusion which is often associated with pleurisy and pneumonitis; recurr are common. The exudate may be he The postmyocardial infarction syndro distinguished from the 2 conditions been mistaken: (1) from extensi infarction, by the pleuro pain and the absence of addi electrocardiogram, and (2) fr

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

tion, by the finding of evidence of pericarditis. "Enlargement of the heart," which is often erroneously diagnosed on x-ray evidence, can be ruled out by serial x-ray studies which demonstrate rapid shrinking of the heart silhouette. It is estimated that the postmyocardial infarction syndrome complicates from 3 to 4% of the cases of myocardial infarction. Its etiology is unknown, but it is thought that sensitization by necrotic muscle tissue may be the responsible factor. The syndrome is benign, but relapses may occur repeatedly. Adrenal steroids promptly abolish fever and pain, but their use should be reserved for patients with severe intractable pain or with a prolonged course of illness. Anticoagulant therapy is dangerous. A case is reported in which the use of anticoagulants led to fatal cardiac tamponade.

Macroglobulinemia of Waldenstrøm: Brief Review with Description of Cases. J. O. Alvsaker. Tidsskr. norske laegefor. 78:1171-1173 (Dec. 1) 1958 (In Norwegian) [Oslo].

Macroglobulinemia is a chronic condition with fatal outcome, which occurs in both sexes but especially in older men. The symptomatology is marked by vague general symptoms, such as asthenia, dyspnea, anorexia, and loss of weight. Often after several years there is a tendency to bleeding, with hemorrhagic manifestations localized to the skin, mucous membranes, retina, central nervous system, and gastrointestinal tract. Some patients show reduced resistance to infection, and intravascular hemolysis has been described. Clinical examination often reveals general lymph node inflammation and in some cases splenomegaly and hepatomegaly. The sedimentation reaction is greatly increased. On fractionated serum albumin determinations, hyperglobulinemia with inverted albumin-globulin index is found. Establishment of macroglobulins on ultracentrifugation is pathognomic. Macroglobulinemia may be accompanied by disturbances in the lipid metabolism with reduced cholesterol in the blood. The primary disturbance seems to be localized in the reticuloendothelial system. In a case of long-continued, greatly increased sedimentation reaction of unknown cause, and in vague hemorrhagic manifestations with increased sedimentation reaction, the blood picture and the electrophoresis diagram will direct attention to macroglobulinemia. While verification of the diagnosis depends on ultracentrifugation, simpler laboratory tests can make the diagnosis probable. Positive formolgel reaction in less than 10 minutes testifies for macroglobulinemia. In the case described, in a man aged 70 years, there was a typical picture of the disorder, early in the course, with marked hyperglobulinemia, characteristic electrophoresis diagram, and 28% macroglobulins seen on ultracentrifugation. The hematological picture was also characteristic, the formolgel reaction being strongly positive and the cholesterol value in the blood slightly reduced. The case is considered as primary macroglobulinemia.

Clinical Experience with the use of Neomycin in Hepatic Coma. W. W. Faloon and C. J. Fisher. A. M. A. Arch. Int. Med. 103:43-53 (Jan.) 1959 [Chicago].

Of the many therapeutic regimens that have been employed in hepatic coma, the withdrawal of protein together with the oral administration of wide-spectrum antibiotics has reportedly given the most favorable results. Observations in the laboratory with which the authors are connected indicated the efficacy of orally administered neomycin in reducing blood ammonia concentrations even when protein feeding was continued. Therefore, they deliberately gave protein by mouth while neomycin was given. The major objective of this regimen was the reduction of ammonia formation by reducing the intestinal bacterial flora while attempting to maintain optimal nutrition. Twenty-two patients with alcoholic cirrhosis were followed during 25 episodes of coma or impending coma. This series included some patients who received acetazolamide (Diamox) or who had gastrointestinal hemorrhage. These might have been the chief factors responsible for precipitating hepatic coma. Since it is likely that such patients will always be found in any extensive series of hepatic coma patients, the authors report their observations on these patients as well as on those in whom neurological disorders developed spontaneously.

Improvement resulted in 23 of the 25 episodes of coma. Eleven of the 22 patients died, but in 9 of these 11 some improvement was noted before death. Eighteen patients received protein from the beginning of therapy with neomycin, and of these 7 lived and 11 died, but some improvement was noted before death in 9 of the latter. Four patients received no dietary protein, and all survived, but of these, 3 had bleeding and thus had protein within the intestinal tract. A decrease in the level of blood ammonia was observed during therapy in 16 of the 18 patients in whom it was determined. Of those whose ammonia levels fell 8 lived and 8 died, with all the patients showing some improvement prior to the final outcome. Death occurred in both patients in whom the ammonia level did not fall during neomycin therapy, and neither patient exhibited improvement. No significant difference in survival rate was observed between patients receiving more than 25 Gm. of protein and those receiving less than 25 Gm. An unfavorable prognosis in these patients was found to be associated with increasing depth of coma after therapy was initiated and with the presence of jaundice.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Serum Triglycerides in Coronary Artery Disease. M. J. Albrink and E. B. Man. A. M. A. Arch. Int. Med. 103:4-8 (Jan.) 1959 [Chicago].

Lipids are transported in serum as constituents of 3 major classes of compounds: cholesterol and its esters, phospholipids, and triglycerides or neutral fat. Most investigations in recent years have centered about the notion that serum cholesterol plays a causative role in the development of coronary artery disease. Although triglycerides rather than cholesterol are chiefly responsible for turbidity of serum and constitute an important fraction of β-lipoproteins, the quantitative estimation of triglycerides has been largely neglected in studies of serum lipids in coronary artery disease. The present research was undertaken to observe the interrelation of the 3 major serum lipid fractions. The subjects were 100 patients with a history of myocardial infarction. The group included 82 men and 18 women, ranging in age from 21 to 78 years, the greatest number being in their 50's. Control subjects included healthy medical students, industrial workers, and hospital patients without vascular disease and without known metabolic disorders.

Elevations of serum triglycerides above 5.5 mEq. per liter (about 160 mg. per 100 cc.) occurred in only 5% of normal young adults, in at most 30% of normal men over 50, and, if the effects of acute illness were excluded, in 85 to 90% of patients with coronary artery disease. The authors believe that few, if any, other lipid measurements which have been reported effect such a clear-cut separation between normal and coronary subjects. The observations reported suggest that an error in the metabolism of triglycerides is the lipid abnormality operative in coronary artery disease. It may be that other findings commonly reported in this disease, such as increased cholesterol, increased low-density lipoproteins rich in triglycerides, and prolonged and intensified alimentary lipemia, are secondary to decreased efficiency of triglyceride utilization with resulting accumulation of triglycerides in plasma. It is tempting to speculate on the significance of these findings in relation to the energy metabolism of the heart, particularly in the light of recent evidence that fat is an important source of fuel for the normal myocardium, that triglycerides are turned over with great rapidity by heart tissue, and that lipoprotein lipase occurs in high concentration in myocardial tissue.

The Post-Myocardial-Infarction Syndrome: A Report of 44 Cases. W. Dressler. A. M. A. Arch Int. Med. 102:28-42 (Jan.) 1959 [Chicago].

The hematological picture was also characteristic, the formolgel reaction being strongly positive and the cholesterol value in the blood slightly reduced. The case is considered as primary macroglobulinemia.

Clinical Experience with the use of Neomycin in Hepatic Coma. W. W. Faloon and C. J. Fisher. A. M. A. Arch. Int. Med. 103:43-53 (Jan.) 1959 [Chicago].

Of the many therapeutic regimens that have been employed in hepatic coma, the withdrawal of protein together with the oral administration of wide-spectrum antibiotics has reportedly given the most favorable results. Observations in the laboratory with which the authors are connected indicated the efficacy of orally administered neomycin in reducing blood ammonia concentrations even when protein feeding was continued. Therefore, they deliberately gave protein by mouth while neomycin was given. The major objective of this regimen was the reduction of ammonia formation by reducing the intestinal bacterial flora while attempting to maintain optimal nutrition. Twenty-two patients with alcoholic cirrhosis were followed during 25 episodes of coma or impending coma. This series included some patients who received acetazolamide (Diamox) or who had gastrointestinal hemorrhage. These might have been the chief factors responsible for precipitating hepatic coma. Since it is likely that such patients will always be found in any extensive series of hepatic coma patients, the authors report their observations on these patients as well as on those in whom neurological disorders developed spontaneously.

Improvement resulted in 23 of the 25 episodes of coma. Eleven of the 22 patients died, but in 9 of these 11 some improvement was noted before death. Eighteen patients received protein from the beginning of therapy with neomycin, and, of these, 7 lived and 11 died, but some improvement was noted before death in 9 of the latter. Four patients received no dietary protein, and all survived, but, of these, 3 had bleeding and thus had protein within the intestinal tract. A decrease in the level of blood ammonia was observed during therapy in 16 of the 18 patients in whom it was determined. Of those whose ammonia levels fell, 8 lived and 8 died, with all the patients showing some improvement prior to the final outcome. Death occurred in both patients in whom the ammonia level did not fall during neomycin therapy, and neither patient exhibited improvement. No significant difference in survival rate was observed between patients receiving more than 25 Gm. of protein and those receiving less than 25 Gm. An unfavorable prognosis in these patients was found to be associated with increasing depth of coma after therapy was initiated and with the presence of jaundice.

Remission of the Hematological and Clinical Symptoms in Acute Leukemia After Treatment with Prednisone and 6-Mercaptopurine. P. Longo. Policlinico (sez. prat.) 65:1639-1648 (Oct. 27) 1958 (In Italian) [Rome].

Complete remission of the hematological and clinical symptoms was obtained by treating a 17-year-old youth with acute leukemia with prednisone and 6-mercaptopurine. The first symptoms of the disease occurred in the patient one year before admission to the hospital. Upon admission the patient received several 200-cc. transfusions of fresh whole blood and treatment with analeptic drugs and vitamins. Prednisone and 6-mercaptopurine were given 4 days later. Prednisone was administered first in a dose of 30 mg. per day and later in a dose of 80 mg. per day, which was continued for 22 days; 6-mercaptopurine was administered in a dose of 150 mg. every 24 hours, which was continued throughout the period the patient remained in the hospital and was reduced to 100 mg. per day after discharge from the hospital. Three additional 200-cc. blood transfusions were made before discharge from the hospital.

The condition of the patient was critical during the first 15 days he spent in the hospital. A gradual improvement could be observed after this period. The patient started to take some food, and the temperature tended to decrease. Later a marked improvement of the objective and subjective conditions followed day by day. Swelling of the lymph nodes became reduced and almost disappeared. The contour of the spleen and of the liver became normal. The infection of the mouth and throat healed, and no trace was left of it. The color of the patient became normal, and the body weight, which was 57.3 kg. (126 lb.) on admission, went up to 65 kg. (143 lb.). Fever disappeared completely 6 weeks after admission, at which time the appetite increased markedly and the digestive process was normal. The patient was discharged from the hospital after 16 weeks and, when seen 1 month later, was found to be in good general condition. The hematological examination at this time gave normal results.

Armchair Treatment with and Without Anticoagulants in Cardiac Infarction. S. Helander. Acta. med. scandinav. 162:351-359 (no. 5) 1958 (In English) [Stockholm].

The author reports on 307 patients with cardiac infarction, who were admitted within 3 days of onset and received armchair treatment, with and without anticoagulants, at the Karolinska Sjukhuset in Stockholm between 1952 and 1956. The aim of the armchair treatment was to relieve the heart muscle. The patients were divided into 3 groups according to the severity of their condition. Group 3 included the mild cases; group 2 included patients with the usual clinical symptoms of cardiac infarction, with fever, raised erythrocyte sedimentation rate, and leukocytosis; and group 1 included the most severely ill patients, with additional manifestations of shock and a fall in blood pressure. Fifteen of the 307 patients died within 12 hours after admission and are not included. Of the remaining 292 patients, 112 were treated in an armchair and were given anticoagulants (10% of these died): 100 were treated in an armchair without anticoagulants (15% of these died); and 80 were treated with bed rest and anticoagulants (26% of these died). It is significant that 6% of the patients from group 2 who received armchair treatment with anticoagulants and 16% of the patients from the same group who received armchair treatment without anticoagulants died, whereas of the patients of group 2 who received treatment with anticoagulants and bed rest 22% died. Most of the patients who died showed ominous prognostic signs, such as arrhythmia in cardiac failure or heart block, and about half of them had had a previous attack of cardiac infarction, as postmortem examination had revealed. Of the patients treated in an armchair, there were 14 who had had a previous attack of infarction among the 25 patients who died. Twelve patients of the armchair group had a septal infarction, against 9 of 21 patients treated with bed rest. The frequency of embolic complications was negligible in all groups and could hardly have had any effect on the mortality.

An analysis of the immediate causes of death in cardiac infarction seems to suggest that armchair treatment lessens the burden placed on the heart muscle and diminishes the risk of occurrence of pulmonary edema. Embolic complications do not seem to have played any role in determining the difference in mortality rates between those treated with anticoagulants and those who did not receive anticoagulants. Armchair treatment seems to be a good prophylaxis against thromboembolic complications in patients with cardiac infarction.

Syndromes of Thyroid Hyperfunction in Old Age: Clinical Study. C. de Nogales Quevedo and M. Santaló Rovira. Med. Clín. 31:83-105 (Aug.) 1958 (In Spanish) [Barcelona, Spain].

Three hundred patients with hyperthyroidism were observed at the hospital of the University of Barcelona; of these patients 20 (17 women and 3 men) were between the ages of 50 and 70 years. The older patients complained of repeated bouts of hyperthyroidism, with cardiac decompensation and periods of either nervousness or depression. Psychic trauma was the only, or the predominant, causal factor of hyperthyroidism in more than half of them. On hospitalization, all these patients reported considerable loss of weight during the past few months, and they all had tachycardia and tremor. Hyperthyroidism was of either the apathetic (Lahey's) type or the type of exophthalmic goiter. Hyperthyroidism of the apathetic type had appeared in 10 women several years after the menopause. The cardiovascular disease was severe, 5 of the patients having atrial fibrillation with complete arrhythmia. Exophthalmos and goiter either were not present or were very mild. The constant psychic feature was depression. Hyperthroidism of the type of exophthalmic goiter appeared in 7 women immediately or shortly after the menopause. The ocular, thyroid, and cardiovascular symptoms were the same as those observed in patients whose exophthalmic goiter had developed at a younger age. The psychic feature was constant nervous tension.

The treatment of these older patients with hyperthyroidism consisted of the administration of methylthiouracil in daily doses which ranged from 0.15 to 0.3 Gm. This dosage was given in 3 or 4 fractional doses for several days during early therapy. Then the patients were placed on maintenance therapy in which the dosage was individually determined and was given for 3 or 4 months until complete remission was obtained (100% satisfactory results were reported in all these cases). Remission has lasted for several years since discontinuation of the treatment in all the patients but 2. These 2 patients had a recurrence 7 months and 1 year, respectively, after the first remission, but a second complete remission, which has lasted several months, was obtained once more from the administration of methylthiouracil. The authors conclude that thyrotoxic goiter in older patients is a clear indication for treatment with methylthiouracil; the drug is well tolerated. Surgical treatment of hyperthyroidism in this age group is indicated only in cases of nodular goiter or when canceration of the goiter is threatening. Seven representative cases are reported.

A Comparative Study of the Effect of Transfusion of Fresh and Preserved Whole Blood on Bleeding in Patients with Acute Leukemia. E. J. Freireich, P. J. Schmidt, M. A. Schneiderman and E. Frei. New England J. Med. 260:6-11 (Jan. 1) 1959 [Boston].

Gross bleeding in patients with acute leukemia is closely related to thrombocytopenia. With the development of plastic and other nonwettable surfaces, the transfusion of viable platelets that circulate for 5 to 7 days was demonstrated, but because of difficulties involved in platelet transfusion, it cannot be employed as a standard therapeutic procedure. For these reasons, freshly drawn whole blood, collected over nonwettable surfaces, has been utilized for the treatment of thrombopenic bleeding in patients with acute leukemia. Preliminary clinical observations of the effect of fresh whole-blood transfusion on hemorrhage in acute leukemia indicated definite benefit in only an occasional patient. Moreover, the extreme irregularity of hemorrhage in these patients, as well as the frequently transient nature of the hemostatic effect, often made clinical judgement of effectiveness extremely difficult. In view of the extra time, effort, and expense involved in utilizing fresh blood for transfusion, it seemed necessary to evaluate quantitatively the effect of this treatment.

The present study was designed as a controlled, comparative blind study, with banked whole blood as a control material. It was found that fresh blood collected in disodium ethylenediaminetetraacetate alters hemorrhage in patients with acute leukemia more frequently than bank blood collected in acid citrate dextrose and stored at 5 C for 2 to 9 days. Favorable responses to fresh blood were observed in 10 of 14 bleeding episodes. Platelet levels after fresh-blood transfusion were significantly higher than those after bank-blood transfusion. However, all levels were well below the platelet level ordinarily associated with absence of hemorrhage (50,000 per cubic millimeter). The platelet levels after fresh-blood transfusion were not significantly different for those showing a clinical effect and those showing none.

SURGERY

An Analysis of the Pathologic Anatomy of Pulmonary Arteriovenous Aneurysms with Particular Reference to the Applicability of Local Excision. L. H. Bosher, D. A. Blake and B. R. Byrd. Surgery 45:91-104 (Jan.) 1959 [St. Louis].

The authors analyzed the gross pathological anatomy of pulmonary arteriovenous aneurysms in 252 patients whose cases were collected from the world literature and in 98 patients whose cases have not been previously reported. The anatomic distribution of pulmonary arteriovenous aneurysms in the 350 patients showed a wide variability, ranging from multiple, diffuse, pulmonary telangiectasia to a single large aneurysm. Twelve cases are recorded in which a systemic artery joined the aneurysm. About 64% of the patients had single lesions, and in 75% the disease was unilateral. Angiography should be performed preoperatively in all patients to detect fistulas which are not visualized on plain chest roentgenograms. Of the 350 patients, 239 were operated on, and on 19 of these, bilateral resections were performed. There were 13 operative deaths. Seventeen patients, less than 10 years old, were operated on, and all but one of these obtained good results.

A technique for performing local excision of arteriovenous aneurysms in a bloodless field is reemphasized, and it is estimated that this can be employed in at least 50% of all cases, in preference to segmental resection or lobectomy. To illustrate the applicability of this technique, the case of a

39-year-old man with a large subpleural aneurysmal sac on the underface of the anterior segment of the left upper lobe is reported. The technique was utilized as follows: After occlusion of the main pulmonary artery and superior pulmonary vein together with the main bronchus, the sac was entered and the vascular orifices were observed, two of arterial origin, 6 mm. in diameter each, and one of venous origin, 1 cm. in diameter. The two arteries were ligated individually close to the base of the sac, but the large vein was dissected some distance proximally where it joined a vein from the anterior segment. The postoperative course of this patient was uneventful. Reexamination one year later revealed that he had gained 20 lb. (9.1 kg.) and that the previously noticed shortness of breath on exertion was no longer present. It is urged that surgeons should report any cases of late recurrence which might elucidate further the problem of latent small pulmonary arteriovenous fistulas.

Clinicopathologic Observations on the Fate of Arterial Freeze-Dried Homografts. A. W. Humphries, W. A. Hawk, V. G. de Wolfe and F. A. Le Fevre. Surgery 45:59-71 (Jan.) 1959 [St. Louis].

The authors report on 525 patients with occlusive and aneurysmal disease, who were operated on and in whom arterial freeze-dried homografts were placed in the abdomen and in the lower extremity. In 31 patients the grafts were initially unsuccessful because of inadequate runoff. There was a total of 56 deaths; 4 of these were caused by technical failure of an inadequate proximal anastomosis in patients with aneurysm; of 10 patients who died as a result of failure of the homograft itself, 6 had local infections with resultant rupture of the graft, 2 died of erosion of the homograft as it pulsated against the cut end of the patient's own calcified vessel, and 2 died of rupture of a saccular aneurysm. Causes associated with major surgery, but not specifically with a graft, were responsible for the other 42 deaths. These included deaths due to myocardial infarction, rhythmic changes in the heart, usually ventricular fibrillation, and cerebral anoxia. A total of 438 patients thus were available for follow-up studies. Of these, 70 have incurred some incident in their postoperative course that has resulted in the loss of distal pulses and a presumed failure of the graft. In 368 patients the grafts remained successful for periods ranging up to 4½ years.

Of the 70 patients in whom late graft shutdown has occurred, 15 had aortoiliac and 55 had femoropopliteal grafts. All these patients had occlusive disease. Five had grafts which were lost through primary wound infections in the leg. These, combined with the 6 deaths due to infection, make a total of 11 infections (or 2%). In the presence of infection with associated proteolytic digestion of the homograft, the only safe procedure is to remove the graft, tie off the patient's own vessels, and abandon the project. Thirty of the late graft shutdowns were regrafted. Two of them were initially unsuccessful, a second late shutdown occurred in 2, and the remaining 26 regrafts are still potent and functioning. Most of the late graft shutdowns occurred in the femoropopliteal area due to the smaller caliber of the vessel, and most of the shutdowns occurred within the first year. Pathological findings in 33 grafts, 30 of which were obtained from regrafting and 3 from patients whose deaths occurred late, were as follows. Arteriosclerosis occurred in 7 of the grafts removed; multiple aneurysmal dilatation occurred in 1 case; arteriosclerotic aneurysm occurred in 1 femoral graft; saccular aneurysm developed in 4 grafts; 1 dissection occurred within a graft; and there were 11 instances of rupture due to infection.

Long-standing good results may be expected in those patients with aneurysm who survive the surgical intervention. One may also expect a certain acceptable percentage of late shutdowns in patients with occlusive disease, not necessarily of clinical importance, more in femoropopliteal than in aortoiliac grafts, which is in direct proportion to the size of the vessel, to degree of "activity" of disease, and undoubtedly to other as yet unknown factors. However, the longer a graft remains functional, the better the chances are that it will continue to remain functional.

Congenital Pulmonary Arteriovenous Fistula: Report of a Case and Review of the Literature. A. G. Fletcher Jr., K. Banerjee, T. Takaro and W. M. Bond. Indian J. Surg. 20:416-422 (Oct.) 1958 (In English) [Madras].

The authors report on a 28-year-old man with pulmonary arteriovenous fistula for which he was operated on at the Wanless Tuberculosis Sanatorium in Miraj, India. There was a history of repeated attacks of pain in the lower chest on the left, but there was no history of cough, expectoration, or fever. Chest roentgenograms revealed a homogeneous circumscribed area of increased density in the left lower lung field toward the periphery. On fluoroscopy the lesion was shown to be anterior in position, probably in the lingula of the upper lobe. It was considered to be a circumscribed caseonecrotic focus or tuberculoma. The patient was given antimicrobial therapy for 6 months, on which he gained 17 lb. (7.7 kg.) in weight, but the lesion did not respond to therapy. A left-sided thoracotomy was performed, and on exposing the lung a soft, rounded, pulsating mass located just beneath the visceral pleura was found in the superior portion of the lingular segment. A strong thrill was palpable on slight compression of the lesion, which appeared to be a pulmonary arteriovenous fistula. Lingulectomy was performed to remove the lesion. The patient made an uneventful recovery and was free of symptoms when last seen one year after the operation. He apparently was the first patient operated on for pulmonary arteriovenous fistula and reported on in India. The cases of 40 patients with pulmonary arteriovenous fistula, who were operated on, were collected from the literature. There was only one postoperative death.

Pulmonary arteriovenous fistula is a relatively uncommon congenital defect with a hereditary tendency. The typical clinical picture is that of cyanosis and clubbing in a patient with a normal heart and a lung lesion revealed by chest roentgenogram. Polycythemia may be severe, but in some patients it may be absent or minimal. The diagnosis may be confirmed by laminography or angiocardiography. Dangerous complications reported by other workers were hemoptysis, hemothorax, brain abscess, bacterial endarteritis, and cerebral thrombosis. The treatment of choice is surgical resection of the involved portion of the lung after carefully checking for multiple lesions.

Intra-Aortic Blood Transfusion. V. S. Ermakov. Khirurgiya 34:23-27 (no. 11) 1958 (In Russian) [Moscow].

The author reports on 10 cases in which transfusion of blood into the abdominal aorta was employed in grave surgical shock and in blood loss. A good and stable effect was seen in 7 patients who recovered; an effect of short duration was obtained in 2 patients. The author's observations show that the intra-aortic transfusion of blood is a powerful therapeutic measure which may be employed in prophylaxis and in combating severe shock. The rise in arterial blood pressure and an improvement in the cardiac activity and respiration appeared directly after the injection of the first portions of blood. The total amount of blood injected in shock was 70 to 140 ml., while in shock combined with blood loss it was 250 to 300 ml. The author suggests a special method for intra-aortic blood transfusion, which enables one to control the aortic blood pressure and, consequently, to determine the required amount of blood for the achievement of the effect.

Spasm: A Preliminary Clinical Report on a Nondestructive Method for the Relief of So-Called "Mass-Reflex" Spasm. D. Munro and E. L. Spatz. New England J. Med. 260:1-6 (Jan. 1) 1959 [Boston].

This paper deals only with the so-called mass-reflex spasm. This occurs solely in connection with injuries of the spinal cord between the 3rd cervical and 1st sacral segments. Of the 3 characteristics of the mass-reflex spasm, the first is an excessive, self-propagating, maximal motor response to a minimal sensory stimulus. Muscular overresponse takes the form of a strong, spastic, slowly released movement of the various parts of the limb at the individual joints. The motion may be either pure flexor, pure extensor, alternate, or mixed. If the spasm causes pure flexion, the great toe is first dorsiflexed, followed by fanning of the other toes and dorsiflexion of the ankle. This activity is rapidly propagated without further external stimulus to the flexors of the knee, then to the adductors of the thigh, the flexors of the thigh, and the paraspinal and psoas muscular groups with flexion at the waist; if the cord injury is high enough, there is a spread to the abdominal muscles, as well as the adductors and flexors of the arm, forearm, and hand.

If not corrected, and as the various muscle groups are involved one by one, the position of the legs and body becomes firmly fixed in either flexion, if the spasm started as pure flexor spasm, or extension, if it started as pure extensor spasm. Mixed flexor-extensor spasm will present a confusing picture of limb fixation, but the basic self-provocative nature, progression, and distribution will be present in any case. The second characteristic of the mass-reflex spasm is its tendency to form a vicious circle as the result of repeated sensory stimuli, which originate in the area of muscle and tendon contractions and which, in turn, produce more muscle responses out of which arise, in their turn, more motor-producing sensory stimuli. The third characteristic is the semi-isolated reaction, which involves in its own vicious circle the bladder, the external urethral sphincter, the rectum, and the anal canal.

A previously unreported method designed to eliminate the mass-reflex spasm in patients with spinal-cord injuries is reported. This method has been based upon the hypothesis that such spasm differs from other spasms in that, in its pure form, it is self-propagating from the periphery, progresses centrally, and has circular form. The urinary bladder, the external urethral sphincter, and the intestine-emptying mechanism are all adversely affected by the mass-reflex spasm and may remain so after the skeletal-muscle spasm is abolished. This visceral spasm is also self-propagating and circular in form. Permanent abolition of spasm of the detrusor and external urethral sphincter can be brought about by properly placed procaine and, rarely, by alcohol injections of the sciatic roots through the sacral foramens in the former condition and by injection of procaine into the internal pudic nerves in the latter condition. Destructive permanent denervations, whether surgical or chemical, of the parasympathetic and somatic nerve supply to the bladder and the external urethral sphincter, as well as destruction of the urethra by punch operation, are not necessary and are practically always contraindicated. Previous abolition of skeletal mass-reflex spasm is an essential prerequisite if this therapy is to succeed. Selective

39-year-old man with a large subpleural aneurysmal sac on the underface of the anterior segment of the left upper lobe is reported. The technique was utilized as follows: After occlusion of the main pulmonary artery and superior pulmonary vein together with the main bronchus, the sac was entered and the vascular orifices were observed, two of arterial origin, 6 mm. in diameter each, and one of venous origin, 1 cm. in diameter. The two arteries were ligated individually close to the base of the sac, but the large vein was dissected some distance proximally where it joined a vein from the anterior segment. The postoperative course of this patient was uneventful. Reexamination one year later revealed that he had gained 20 lb. (9.1 kg.) and that the previously noticed shortness of breath on exertion was no longer present. It is urged that surgeons should report any cases of late recurrence which might elucidate further the problem of latent small pulmonary arteriovenous fistulas.

Clinicopathologic Observations on the Fate of Arterial Freeze-Dried Homografts. A. W. Humphries, W. A. Hawk, V. G. de Wolfe and F. A. Le Fevre. Surgery 45:59-71 (Jan.) 1959 [St. Louis].

Spasm: A Preliminary Clinical Report on a Nondestructive Method for the Relief of So-Called "Mass-Reflex" Spasm. D. Munro and E. L. Spatz. New England J. Med. 260:1-6 (Jan. 1) 1959 [Boston].

This paper deals only with the so-called mass-reflex spasm. This occurs solely in connection with injuries of the spinal cord between the 3rd cervical and 1st sacral segments. Of the 3 characteristics of the mass-reflex spasm, the first is an excessive, self-propagating, maximal motor response to a minimal sensory stimulus. Muscular overresponse takes the form of a strong, spastic, slowly released movement of the various parts of the limb at the individual joints. The motion may be either pure flexor, pure extensor, alternate, or mixed. If the spasm causes pure flexion, the great toe is first dorsiflexed, followed by fanning of the other toes and dorsiflexion of the ankle. This activity is rapidly propagated without further external stimulus to the flexors of the knee, then to the adductors of the thigh, the flexors of the thigh, and the paraspinal and psoas muscular groups with flexion at the waist; if the cord injury is high enough, there is a spread to the abdominal muscles, as well as the adductors and flexors of the arm, forearm, and hand.

If not corrected, and as the various muscle groups are involved one by one, the position of the legs and body becomes firmly fixed in either flexion, if the spasm started as pure flexor spasm, or extension, if it started as pure extensor spasm. Mixed flexor-extensor spasm will present a confusing picture of limb fixation, but the basic self-provocative nature, progression, and distribution will be present in any case. The second characteristic of the mass-reflex spasm is its tendency to form a vicious circle as the result of repeated sensory stimuli, which originate in the area of muscle and tendon contractions and which, in turn, produce more muscle responses out of which arise, in their turn, more motor-producing sensory stimuli. The third characteristic is the semi-isolated reaction, which involves in its own vicious circle the bladder, the external urethral sphincter, the rectum, and the anal canal.

A previously unreported method designed to eliminate the mass-reflex spasm in patients with spinal-cord injuries is reported. This method has been based upon the hypothesis that such spasm differs from other spasms in that, in its pure form, it is self-propagating from the periphery, progresses centrally, and has circular form. The urinary bladder, the external urethral sphincter, and the intestine-emptying mechanism are all adversely affected by the mass-reflex spasm and may remain so after the skeletal-muscle spasm is abolished. This visceral spasm is also self-propagating and circular in form. Permanent abolition of spasm of the detrusor and external urethral sphincter can be brought about by properly placed procaine and, rarely, by alcohol injections of the sciatic roots through the sacral foramens in the former condition and by injection of procaine into the internal pudic nerves in the latter condition. Destructive permanent denervations, whether surgical or chemical, of the parasympathetic and somatic nerve supply to the bladder and the external urethral sphincter, as well as destruction of the urethra by punch operation, are not necessary and are practically always contraindicated. Previous abolition of skeletal mass-reflex spasm is an essential prerequisite if this therapy is to succeed. Selective anterior-rootlet rhizotomy may be indicated in certain especially selected cases as a method for reducing the mass-reflex spasm.

Injection with procaine, or its derivatives, of the sciatic nerve in the thigh and of the ulnar, median, and radial nerves in the arms shows promise of further success in the control of spasm associated with partially injured spinal cords even in quadriplegic patients. The sciatic nerves should be exposed for injection through a posterior upper-thigh approach at the first injection. The procaine solution should be injected under direct vision into the nerve trunk. The epineural sheath must not be incised. Silver clips should be so placed as to indicate the place and plane of future injections, which should then be done with fluoroscopic guidance of the injecting needle. The ulnar, median, and radial nerves should all be exposed for injection under direct vision at the level in the arm where they surround the brachial artery. The physiological implications of the control of abnormal postural reflex activity, as demonstrated in the cases reported, warrant further investigation.

Symptomatic Myelolipoma of the Adrenal Gland: Report of a Case and Review of the Literature. L. Parsons Jr. and J. E. Thompson. New England J. Med. 260:12-15 (Jan. 1) 1959 [Boston].

Myelolipoma of the adrenal is rare, and so far has been described only as an incidental finding at autopsy. The case reported here is of interest, because the authors believe it to be the first recorded case in which a myelolipoma reached a large enough size to produce symptoms necessitating operative removal. The patient was a 51-year-old woman, hospitalized in October, 1956, with a 2-month history of malaise, anorexia, and poorly localized discomfort in the upper abdomen. These symptoms were increasing. In the month before admission there had been occasional nausea and vomiting, as well as a 5.4-kg. (12-lb.) weight loss. The discomfort was unrelated to foods. Intermittent headaches were a complaint of long standing. In the right upper quadrant of the abdomen there was a large, rounded mass extending 5 fingerbreadths below the costal margin in the midclavicular line. The mass was slightly tender; it moved with respiration and with manipulation.

At exploratory operation, the colon was seen to overlie a large retroperitoneal mass. The retroperitoneal space was entered, and an ovoid tumor was seen lying on the vena cava just above the right kidney. Mobilization of the tumor was readily performed, except at its upper pole where it was contiguous with a thinned-out rim of adrenal tissue. The patient made an uneventful recovery, with relief of the symptoms. There has been no evidence of recurrence. The specimen was a large, oval mass, 25 cm. long, 13 cm. wide, and 12 cm. thick. It weighed 1,250 Gm. Sectioning of the growth revealed adipose tissue, the structure and organization of which were similar to those seen in lipomas in general. The adipose tissue was traversed by bundles of fibrous tissue. The purplish areas observed on gross examination represented, variously, adipose tissue, markedly congested sinusoids, fresh and old hemorrhages, and occasional clusters of lymphocytes, as well as bone-marrow tissue with hematopoietic elements. The peripheral orange-yellow tissue described on gross examination was adrenocortical tissue beneath a fibrous capsule. No adrenal medulla was seen in the many sections examined.

The Use of Intravenous Pituitrin in Treatment of Bleeding Esophageal Varices. S. I. Schwartz, H. W. Bales, G. L. Emerson and E. B. Mahoney. Surgery 45:72-80 (Jan.) 1959 [St. Louis].

The authors treated 11 patients with acutely bleeding esophageal varices by intravenous administration of a commercial posterior pituitary preparation (Surgical Pituitrin) or a commercial preparation of vasopressin injection (Pitressin). The estimated blood loss before the institution of therapy varied between 250 and 1,000 cc. Ten of the 11 patients had alcoholic cirrhosis. A Levin nasogastric tube or an uninflated Sengstaken-Blakemore tube was inserted in 9 of the patients in order to maintain a constant gastric suction and thus decrease regurgitation into the esophagus of gastric fluid. Twenty clinical units of Surgical Pituitrin or Pitressin, usually diluted with 200 cc. of 5% dextrose in distilled water, were administered over a half-hour period, and the nasogastric tube irrigated at half-hour intervals. Rapid infusion is necessitated by the tachyphylactic property of the drugs. Therapy can be repeated at 4-hour intervals if there is evidence of continued or recurrent bleeding. In the group of 9 patients, 25 distinct episodes of acute bleeding were so treated, with prompt control 22 times. The gastric aspirate cleared 5 to 20 minutes after the completion of the intravenous administration of Surgical Pituitrin or Pitressin. In 2 patients in whom transthoracic esophagotomy resulted in brisk "arterial"-type bleeding, which obscured the surgical field and made identification of the individual varices extremely difficult, 20 units of Surgical Pituitrin were administered over a period of 3 minutes, with a dramatic reduction in the intensity of the bleeding, thus making the individual varices more apparent for suture.

Surgical Pituitrin and Pitressin are worthwhile additions to the therapy of bleeding varices. Direct portal venous pressure measurements in patients with esophageal varices have shown that intravenously administered Surgical Pituitrin results in a rapid and marked lowering of portal pressure, equivalent to the level achieved by portacaval shunt. The drugs have proved effective in the control of acutely bleeding esophageal varices and have been helpful in facilitating transesophageal ligation of bleeding varices. It is recommended that an intravenous regimen with Surgical Pituitrin or Pitressin be given an initial trial in the control of bleeding in view of the distinct advantages over balloon tamponade.

Anastomosis Between the Subclavian Artery and the Aorta in Surgical Treatment for Coarctation of the Aorta. T. De Nunno and R. Gentilli. Minerva cardioangiol. 6:513-518 (Oct.) 1958 (In Italian) [Turin, Italy].

A successful anastomosis between the subclavian artery and the aorta, according to the technique of Blalock, was performed on 4 patients with coarctation of the aorta, aged between 16 and 30 years. The considerable length of the constricted segment of the aorta in 3 patients and a laceration of the upper segment of the aorta which occurred during operation made unfeasible an end-to-end anastomosis between the 2 segments of the aorta. Interruption of the subclavian artery did not cause trophic disturbances in the contiguous upper extremity because of an abundant collateral blood supply. The blood supply of the lower extremities was also adequate, being confirmed by preoperative and postoperative blood pressure recordings. The arterial blood pressure was about 210/90 mm. Hg in the upper left extremity and about 100/90 mm. Hg in the lower extremity before the operation. These values approached each other closer in these patients after the operation, being approximately 140/80 mm. Hg in the upper extremities and the same or slightly lower in the lower extremities 10 days after the operation. The patients were well 2 months after the operation. Vertigo, headache, and head pulsation disappeared in those instances in which they were present before the operation, and blood pressure in the lower and upper extremities showed insignificant changes from previous recordings. Anastomosis between the subclavian artery and the aorta thus permitted the reestablishment in this series of patients of a circulatory condition close to the normal pattern.

Development of Primary Pyloric Hypertrophy in Adults in Relation to the Structure and Function of the Pyloric Canal. S. C. Skoryna, H. S. Dolan and A. Gley. Surg. Gynec. & Obst. 108:83-92 (Jan.) 1959 [Chicago].

Adults with pyloric hypertrophy exhibit ill-defined but somewhat ulcer-like symptoms. The variable symptomatology and difficulty in distinguishing with absolute certainty between benign pyloric stenosis and malignant tumors of this region account for the fact that a proportion of these cases will continue to be undiagnosed before surgical exploration. The authors call particular attention to the relationship of the development of primary pyloric hypertrophy in adults to the structure and function of the pyloric canal. The histories of 6 adults with pyloric hypertrophy, who were studied in the department of surgery of St. Mary's Hospital and of the Royal Victoria Hospital, Montreal, are presented. Their ages ranged from 31 to 61 years. All were operated on, and the diagnosis of pyloric hypertrophy was confirmed by histopathological studies. The structure of the pyloric canal is described on the basis of anatomic findings. The structure of the circular musculature of the pyloric canal appears to be of primary significance in this region. It consists of circular muscle fibers forming a distal (pyloric) loop and a proximal (intermediate) loop enclosing an area of circular fibers which are parallel on the greater gastric curvature side and by convergence form a muscle torus on the lesser curvature. It is concluded that the development of the primary pyloric hypertrophy in adults is related to this structure of the circular muscle layer of the pyloric canal. The physiological evidence for the existence of a pyloric canal mechanism rather than of a pyloric sphincter is discussed.

Primary pyloric hypertrophy in adults is divided into (1) a focal form (torus hypertrophy), (2) a diffuse form associated with proximal lesions, and (3) a diffuse form without other lesions. It is suggested that a congenital neuromuscular dysfunction of the pyloric canal mechanism forms a common basis for both the infantile and the adult pyloric hypertrophy. The relative incidence of each form appears to be determined by the extent of the normal regression in the circular musculature of the pyloric canal during early infancy and by the action of secondary factors during adult life.

Perforated Gastric-Duodenal Ulcers and Their Treatment. M. Pastori. Minerva chir. 13:1263-1267 (Nov. 15) 1958 (In Italian) [Turin, Italy].

The author reports on 119 patients with peptic ulcer who had received surgical treatment since 1937. Duodenal ulcer was present in two-thirds of the patients. The average age of the patients was 35 years. The series included only 4 female patients. The greatest incidence of the disease was observed in spring and in autumn. Perforation was treated by gastroenterostomy in 32 patients (mortality rate, 25%), by resection in 7 (mortality rate, 28%), and by simple suture in 80 (mortality rate, 12.5%). Gastroenterostomy had been used earlier but recently gave way to other surgical methods. There were no deaths among 32 patients treated recently by a simple suture. For this reason the author has selected simple suture, complemented by continual aspiration before and after the operation, as the procedure of choice in the treatment of perforated ulcer. Gastric resection, though, remains the most efficacious surgical procedure for treatment of ulcerous disease in the course of its normal development.

The Management of Massive Hemorrhage from Diverticular Disease of the Colon. C. M. Earley Jr. Surg. Gynec. & Obst. 108:49-60 (Jan.) 1959 [Chicago].

This report reviews observations on 23 patients with massive bleeding associated with diverticular disease of the colon, who were treated at the Medical College of Virginia Hospitals, Richmond, from January, 1952, to August, 1957. They represented 4.5% of the 486 patients diagnosed during this time as having diverticulosis. No attempt was made to study patients with occult or minimal bleeding. Rather, this article is concerned with bleeding sufficiently massive to be noticed by the patient and to cause him to seek medical attention. Other possible causes for the bleeding must be ruled out. The ages of the 23 patients ranged from 44 to 81 years, the average age being 65 years. There were 14 women and 9 men. Hypertensive cardiovascular disease was present in 13. One patient had 4 hospital admissions with massive bleeding; 5 others had 2 admissions each. Data on all 23 patients are tabulated, and 8 especially interesting case histories are described in detail.

The initial care is conservative, with supportive therapy including adequate blood replacement. Most patients will respond to it and cease to bleed quite as suddenly as they began. The average volume of blood administered to the 16 patients managed conservatively was 1,000 cc. per hospital admission. The 7 patients requiring surgical treatment for control of hemorrhage received an average of 6,000 cc. of blood each. A review of the literature revealed a total of 23 patients who were treated surgically in order to control hemorrhage from colonic diverticular disease. Most of these procedures were performed as emergencies, and most of the patients were over 60 years old. At operation, all of the colon containing diverticula should be resected, unless the actual bleeding point can be identified. In a bleeding patient too critically ill to tolerate resection or colectomy, proximal ileostomy or colostomy may be helpful, although there is no certainty that the bleeding will stop after this procedure.

Fibrinolysis and Hypofibrinogenemia: Three Cases. P. H. Sørensen. Ugesk. laeger 120:1669-1674 (Dec. 11) 1958 (In Danish) [Copenhagen].

Fibrinolysis is thought to originate by the introduction of lysokinase into the blood stream, by the release of tissue activators, or by inactivation of inhibitors. Hypofibrinogenemia may be a result of the fibrinolysis, which can cause a fibrinogen consumption increased beyond the production ability of the liver. In the same way a powerful stimulation of the coagulation process on release of tissue thromboplastin can cause hypofibrinogenemia. Finally, there may be so strong an effect on the liver that reduced liver function and hypofibrinogenemia result. The first of the cases reported was that of a woman, aged 60 years, with cancer of the stomach and extensive metastases. Profuse bleeding from the urinary tract developed. Hypofibrinogenemia and fibrinolysis were established. In spite of blood transfusion and administration of plasma and fibrinogen, the patient died 5 days after the beginning of the bleeding. In a multipara, aged 33 years, admitted because of premature separation of the placenta, there were shock, fibrinolysis, and slight hypofibrinogenemia. Treatment with dextran, blood, fibrinogen, and pitupartin was applied; the patient recovered. In the third instance, in a man, aged 60 years, with metastasizing cancer of the prostate, afibrinogenemia and fibrinolysis leading to cutaneous and cerebral hemorrhage developed shortly before death.

Debricin—Clinical Experiences with a New Proteolytic Enzyme in Surgical Wounds. J. F. Connell Jr., L. R. M. Del Guercio and L. M. Rousselot. Surg. Gynec. & Obst. 108:93-99 (Jan.) 1959 [Chicago].

During the past 7 years the burn research group at St. Vincent's Hospital, New York, has been evaluating many enzymatic materials for wound débridement. Debricin proved to be the material that best fulfilled the requirements of an ideal wound débridement agent. This enzymatic agent was developed from ficin in the sap of the fig tree. While highly active against fully denatured protein, the material is only partially active on marginal necrotic tissues. There has been no evidence of systemic toxicity and very little evidence of wound maceration. The powdered material comes mixed with a buffer, and it is activated by mixing the enzyme into a special jelly base. The dry material is stable indefinitely, and, after mixing, the refrigerated material is stable for at least 7 days. The buffered enzyme is most active at pH 5.4. Dilution by strong acid or base producing organisms or antibiotics will tend to be inhibitory.

The material must be applied so that the enzyme-substrate contact is kept at a maximum, and reapplied at 12-to-24-hour intervals to remove inhibitory by-products. There is little difficulty in applying the enzyme to postoperative wounds, deep ulcers, fistulas, sinus tracts, or chest cavities, but flat surface areas, such as shallow ulcers or burns, will tax the surgeon's ingenuity. The best method for the flat surface lesions is to spread the enzyme in a jelly base thickly over the area, cover this with a petrolatum gauze or polyvinyl sheet, and overlay the whole with a thick, absorbent pad. A second method of treating the flat surface eschar is to apply the enzyme as a wet dressing, suspending the buffered material in 100 cc. of isotonic sodium chloride solution and instilling it every 3 to 5 hours through rubber catheters tunneled in an absorbent pad overlying the eschar. The outer surface of this pad should be covered by a polyvinyl sheet to limit evaporation.

The main purpose of using the enzyme is to clean a wound of necrotic tissue elements and to thin out thick exudative collections. The authors used Debricin in 139 patients with a variety of surgical lesions. They found that there is rapid, complete débridement when the enzyme is properly used on various types of ulcerations, deep burns, sinus tracts, and wound infections. Debricin used topically is nontoxic. Antibiotics should be utilized during the course of therapy. The enzyme improves the conditions for healing by its cleansing activity. Its use should be followed by the appropriate surgical procedure to obtain wound closure when indicated. Further studies on local enzyme-antibiotic combinations are in progress.

PEDIATRICS

Esophageal Stricture from Accidental Ingestion of Clinitest Tablets. C. Zimmerman. A. M. A. J. Dis. Child. 97:101-103 (Jan.) 1959 [Chicago].

The author presents the history of a 3½-year-old girl, who was admitted to the Bronx Municipal Hospital Center, New York, on Aug. 6, 1957. The patient began vomiting intermittently 3 weeks prior to admission, about 1 week after a visit to her maternal grandmother, a diabetic. This vomiting progressed, as did anorexia and weight loss, until admission. The vomitus consisted of partially digested food. Physical examination was negative. On the third hospital day the grandmother volunteered the information that the patient had swallowed a Clinitest tablet which was used in urine testing. On the fourth hospital day an esophagogram revealed a stricture of the esophagus just above the level of the carina. Esophagoscopy showed the stricture, and a tube gastrostomy was done. When esophagography was repeated later, it showed complete obstruction at the stricture site. After unsuccessful attempts at dilatation, the stenotic segment was resected, and an end-to-end anastomosis was performed. Four weeks after surgery the patient was eating strained bulky foods.

Four other cases of esophageal stricture caused by Clinitest tablets were found in the literature. Three of these involved children; one also had a complete stricture. An esophagogram will confirm the clinical impression of esophageal stenosis or stricture. If the patient has contact with a diabetic and no etiology is apparent, ingestion of Clinitest should be considered. This tablet can cause a partial or complete stricture of the upper esophagus because of the action of the lye constituent. The copper sulfate content may play a secondary role.

The Infant of the Diabetic Mother. S. S. Gellis and D. Y-Yung Hsia. A. M. A. J. Dis. Child. 97:1-41 (Jan.) 1959 [Chicago].

Despite its large size and apparent maturity the infant of the diabetic mother behaves much like a premature infant and is very frail. About a third of such infants die either in utero or in association with respiratory distress during the early neonatal period. In the 3 decades since the discovery of insulin the problems of the diabetic mother and her infant have received much attention. The authors evaluate the work previously done in this field, and they add observations made on 934 pregnancies of diabetic women in the Joslin Clinic, Boston, between 1940 and 1956. The women were seen in the clinic during pregnancy and were subsequently delivered at the Faulkner Hospital (1940-1950) and the Boston Lying-in Hospital (1950-1956). All the patients were under the care of a team consisting of an internist, 2 obstetricians, an anesthetist, and a pediatrician.

Pregnancy failures were several times commoner in women with diabetes mellitus than in healthy women. This excessive loss was limited mostly to the period after the 28th week of gestation. Comparison of mortality figures showed no significant decrease in the fetal mortality in recent years. Experience and teamwork in therapy seemed to influence the ultimate outcome of such pregnancies. Two maternal factors appeared to influence the fetal mortality: (1) severity of maternal disease and (2) good diabetic control. While there is evidence that diabetic women have a hormonal imbalance during pregnancy and that this is frequently associated with the death of the fetus, there is no proof that female sex hormones either correct this defect or significantly reduce the fetal mortality rate.

Infants of diabetic mothers should be delivered between the 35th and the 36th week of gestation. This prevents the high mortality rate associated with prematurity if delivery takes place too early and the marked increase of stillbirth if delivery takes place closer to term. There is no evidence that the mode of delivery or the type of anesthesia used significantly affects the outcome. Respiratory distress is the principal complication. At postmortem examination, pulmonary hyaline membranes and atelectasis have been the only findings in two-thirds of the infants who die. Hypoglycemia, infections, and congenital anomalies play a minor role in the high neonatal mortality rate. The use of antibiotics, oxygen, mist, or cortisone is not helpful in either the prevention or the treatment of hyaline-membrane disease in these infants. Instead, one has to rely on good pediatric care and general supportive measures. No rational mode of treatment for the infant of the diabetic mother is likely to emerge until the maternal and fetal factors which are responsible for the pathogenesis of pulmonary hyaline membranes are better understood.

Acute Ataxia of Childhood: A Summary of 15 Cases. G. M. Lasater and J. T. Jabbour. A. M. A. J. Dis. Child. 97:61-65 (Jan.) 1959 [Chicago].

Acute cerebellar ataxia is usually a benign disorder subsiding in a few days or weeks. It rarely occurs in adults. The etiology is often undetermined, but in most cases it is thought to be a cerebellar encephalitis of infectious or toxic origin. The authors present a summary of the clinical picture and a discussion of possible etiologies based on reports in the literature and their own observations of 15 cases. The ages of the 15 children ranged from 2 to 12 years, all but 2 being less than 8 years old. The most characteristic clinical feature is the abrupt onset of a grossly ataxic gait. This often occurs in a previously well child and sometimes during the convalescent phase of one of the childhood viral infections. The usual story is that the child awoke in the morning or from his afternoon nap and fell upon attempting to walk. It is then discovered that he walks with a staggering gait, falling frequently. Some patients have intention tremors of the upper extremities. Occasionally nystagmus, dysarthria, hypotonia, and dysmetria are also demonstrated. At times there are signs of dysfunction in other parts of the nervous system, such as lethargy, cloudy sensorium, myoclonic movements, and cranial nerve palsies. There is usually no nuchal rigidity. Fever, nausea, and vomiting may be present. The spinal fluid is often normal but may contain a moderate excess of mononuclear cells and protein. Recovery occurs within 1 week to 8 months, usually in 1 to 3 weeks.

Observations on the 15 children suggested mumps, poliomyelitis, influenza, varicella, and intoxication from insecticides as possible etiological agents. Acute ataxia has also been reported in association with rubeola, rubella, smallpox, scarlet fever, typhoid, infectious mononcleosis, diphtheria, and drug intoxication. The prognosis for complete recovery is good.

Occasionally, symptoms caused by a cerebellar tumor may develop acutely, and this lesion must always be considered in children with acute ataxia. Headache and vomiting are more common with cerebellar tumors, but signs that should especially alert the clinician to the probability of this diagnosis are papilledema, tilting of the head, unilateral dysmetria, nystagmus which is more marked in one direction, 6th nerve palsy, high spinal fluid pressure, and x-ray findings of separation of the sutures, erosion of the clinoid processes, and increased convolutional markings.

The Antibiotic Prophylaxis of Bacterial Complications of Measles. S. Karelitz and H. D. Isenberg. J. Pediat. 54:1-10 (Jan.) 1959 [St. Louis].

A total of 251 children with measles were observed, 173 of them at home and 78 at the Queens General Hospital in Jamaica, N. Y. The ages of these children ranged from 1 to 14 years. Of the 78 hospitalized children, 31 had complications, such at tracheobronchitis, pneumonia, and nonbacterial encephalitis. Antibiotic prophylaxis was given to only 2 children before hospitalization; the remaining 76 children had no antibiotic prophylaxis before their admission to the hospital. While at the hospital the antibiotic therapy, consisting of penicillin or erythromycin, was given to a total of 51 patients, 25 of whom had complications and 26 had none. All the hospitalized patients recovered, whether they were subjected to antibiotic therapy or not. Of the 26 patients who were hospitalized without complications and who were subjected to antibiotic treatment, only one developed a secondary infection; this one child who had been given a diagnosis of measles was found to have influenzal meningitis on the 5th hospital day.

Of the 173 children with measles observed at home, the antibiotic therapy was administered to 88, and the antibiotic prophylaxis to 18. Complications occurred 1 to 11 days after the antibiotic treatment had been discontinued in 14 of the 88 patients. These complications included pneumonia in 1 patient, bronchitis in 1, and otitis media in 12. No complication was manifested during the prophylactic treatment. Complications, such as otitis media and pneumonia, occurred in 18 patients who were not subjected to prophylactic treatment.

The higher complication rate observed in the hospitalized children may be attributed to (1) the difference in the social environment of the 2 groups, (2) the younger age of the children, and (3) the complications already manifested by the children at the time of their hospitalization. The authors emphasize the importance of the prophylactic use of antibiotics in very young and weak children with measles in whom the occurrence of complications could be a threat.

Intravascular Red Cell Aggregation in Children with Heart Disease. F. Arajärvi. Ann. paediat. Fenniae. 4:249-255 (no. 4) 1958 (In English) [Helsinki].

A method is available which makes it possible to observe conjunctival blood vessels and the blood cells circulating in them with the aid of a capillary microscope. In healthy adults and children the red blood cells flow along in the smaller vessels in single or double files; in the larger vessels they flow in a homogeneous mass. In many abnormal conditions, though, the red blood cells adhere in clumps; this adherence is visible in the conjunctival blood vessels as a break-up of the files in the smaller vessels and as definite clumps in the larger ones. The author tried to find answers to the following questions: 1. Do vascular disturbances due to congenital heart disease cause aggregation of the red blood cells? 2. Is there any noticeable difference in the appearance of the intravascular aggregation of the red blood cells if the child has a congenital heart disease or rheumatic fever? 3. Is this method of investigation helpful in the cyanotic newborn infant, particularly in the detection of congenital heart disease?

With the aid of a stereomicroscope, conjunctival blood vessels and the blood cells circulating in them were examined in 96 children. In 48 children with congenital heart disease, no red blood cell aggregation was present unless the child had also an infection, but in 23 children with active carditis, red blood cell aggregations could be found. When the conjunctival blood vessels of 20 newborn infants who were cyanotic were examined with the stereomicroscope, red blood cell aggregations could be found in those who had infections (pneumonia, encephalitis) or brain hemorrhage, but no red blood cell aggregations were found in those with congenital heart disease. This proves that this examination is of value in the differential diagnosis of cyanosis in newborn infants.

Intravascular Red Cell Aggregation in Children with Benign and Malignant Tumors. T. Arajärvi and G. R. Wallgren. Ann. paediat. Fenniae. 4:256-263 (no. 4) 1958 (In English) [Helsinki].

The studies described in this paper were carried out to ascertain: (1) whether a tumor can cause red blood cell aggregation; (2) whether there is any difference in this respect between a benign or a malignant tumor; and (3) whether the aggregation test might be an aid in the early diagnosis of cancer. The stereomicroscope was used in the study of the red blood cells circulating in the conjunctival blood vessels of 100 children who had been hospitalized because of a proved or suspected tumor. The diagnosis was confirmed in all the children by histopathological examination. Red blood cell aggregation was very mild or completely absent in the children with benign tumors or with congenital anomalies. In the children with malignant tumors the red blood cell aggregation was definite. However, aggregation of red blood cells was present also in children who had an infection in addition to a benign tumor or who had only an infectious disease instead of the suspected tumor. The degree of the red blood cell aggregation was proportional to the increase in the sedimentation rate and to the decrease in the hemoglobin value in the children with malignant tumors.

DERMATOLOGY

Chronic Penicillin Urticaria from Dairy Products, Proved by Penicillinase Cures. M. C. Zimmerman. A. M. A. Arch. Dermat. 79:1-6 (Jan.) 1959 [Chicago].

Penicillin is widely used to treat mastitis in cattle. From this use it contaminates, according to an estimate made in 1957, 11% of American milk samples. The contamination of dairy products by traces of penicillin has previously been suspected but never proved as a cause of allergic reactions. The author reports on 3 men and 1 woman in whom proof of the allergenicity of penicillin in dairy products has been based on the following evidence: 1. All the patients had previous allergic reactions (urticaria) to penicillin. 2. The previously known allergic reaction to penicillin was duplicated repeatedly after ingestion of dairy products. 3. The reaction cleared rapidly after injection of 800,000 units of penicillinase (Neutrapen), a penicillin-destroying enzyme with no effect on anything but penicillin. 4. The patients were able to eat dairy products without subsequent allergic reaction if given a prophylactic injection of penicillinase first.

Patients with chronic urticaria in whom penicillin sensitivity is suspected should be given a test injection of penicillinase. If urticaria clears for 4 to 7 days, penicillin sensitivity has probably been the cause. Patients with chronic urticaria, in whom penicillin sensitivity is proved or suspected, should have such dairy products as milk, ice cream, and Roquefort or bleu cheeses containing Penicillium species molds eliminated from their diets. If patients have a flare-up 4 to 7 days after a penicillinase injection, there is residual penicillin in the system which has not been destroyed. Penicillinase injections should be repeated at 4-to-7-day intervals, as necessary, to stop symptoms. If more than 8 days pass before a new outbreak of allergic symptoms after an injection of penicillinase, then the penicillinase has destroyed all the penicillin in the system at that time. A new outbreak suggests either that the patient has had a new exposure to penicillin or that his new reaction is due to some other allergen.

Smooth-Muscle Tumors of the Skin. H. Montgomery and R. K. Winkelmann. A. M. A. Arch. Dermat. 79:32-41 (Jan.) 1959 [Chicago].

The authors report on 33 patients with smooth-muscle tumors of the skin on whom biopsies were performed at the Mayo Clinic. Of the 33 patients, 23 had leiomyoma cutis, 8 had angiomyoma, 1 had nodular or so-called dartoic myoma, and 1 had leiomyosarcoma. The ages of the 8 male and 15 female patients with leiomyomas ranged from 10 to 20 years at the time of onset of the clinical signs. The lesions were located on the face, trunk, or extremities; they progressed slowly and became painful when they were large enough to invade and extend around the bundles or trunks of cutaneous nerves in the deeper part of the cutis and the subcutaneous tissue. Special stains did not reveal any increase in nerve fibrils or nerve trunks. Special histochemical stains proved to be of little value in identifying myomatous tissue. All the angiomyomas occurred as solitary lesions, and all the 8 patients were women. The age of onset was much later in this group than in that with leiomyomas, which sometimes began at birth or shortly thereafter. Dartoic myoma, which occurred in the scrotum of a 54-year-old man, is an uncommon lesion seen primarily by the surgeon because it begins in the subcutaneous tissue and calls for surgical removal. A painful leiomyosarcoma of one year's duration was removed surgically from the right thigh of a 32-year-old woman; the patient apparently had no recurrent tumors 21 years after the surgical excision. Smooth-muscle tumors may be allowed to remain in situ as long as they are asymptomatic. When treatment is desirable, surgical excision is the method of choice. Radiotherapy apparently has no effect on the lesions or the sensations that they produce.

Granuloma Faciale. W. C. Johnson, R. S. Higdon and E. B. Helwig. A. M. A. Arch. Dermat. 79:42-52 (Jan.) 1959 [Chicago].

The authors report on 14 men and 1 woman with granuloma faciale, a dermatosis characterized clinically by elevated, usually asymptomatic, reddish-brown plaques on the face. Tissue sections from the lesions of these patients were examined at the Armed Forces Institute of Pathology for the purpose of determining the natural history of granuloma faciale and its relation to eosinophilic granuloma and of exploring its histogenesis. In 12 of the 15 patients the clinical aspect of the disease was that of a plaque or nodule, and in the remaining 3 it was that of a macula. The lesions were soft, usually brown, red, or purple, and varied from a few millimeters to 8 cm. in diameter. New lesions developed over a period of several months in some of the patients. Five patients were asymptomatic, but 10 noticed varying degrees of itching, burning, stinging, or tenderness. Response to therapy other than wide excision was poor. The lesion in most patients tended to persist indefinitely but varied in color and substance from time to time. The general health of the patients remained good.

No evidence was found of any relationship between granuloma faciale and eosinophilic granuloma of bone or the heterogeneous conditions once called eosinophilic granuloma. The authors' observations suggest that the pathogenesis of granuloma faciale is basically an antigen-antibody or hypersensitivity reaction, the small blood vessels and perivascular tissues in the upper corium of the face being the "shock" tissues. The exciting factors remain unknown, but foci of infection, photosensitivity, trauma, and drugs must be considered.

Genetic Studies on Acanthosis Nigricans. H. O. Curth and B. M. Aschner. A. M. A. Arch. Dermat. 79:55-66 (Jan.) 1959 [Chicago].

The authors carried out genetic studies on patients with acanthosis nigricans at the department of dermatology of the College of Physicians and Surgeons of Columbia University in New York. Three types of this dermatosis have been recognized, namely, benign acanthosis nigricans, malignant acanthosis nigricans, and pseudoacanthosis nigricans. Family studies of 13 patients with the benign type of the disease revealed 9 families in which more than one member was affected. Altogether, there were 27 instances of benign acanthosis nigricans in these 9 families, 14 of the patients being males and 13 females. These figures suggest a genetic background for the benign type of acanthosis nigricans, which shows either regular or irregular dominance. Pseudoacanthosis nigricans, secondary to excessive obesity, may be considered a phenocopy of benign acanthosis nigricans. Pseudoacanthosis nigricans was not included in the authors' genetic studies because environmental factors, such as food intake and personal hygiene, seem to have played a significant role in the pathogenesis of the disorder.

No familial case of malignant acanthosis nigricans has been found. Family studies of 26 patients with the malignant type of the disorder revealed one consanguineous marriage among the parents of the 26 patients. The series of families studied is too small to permit this incidence to be considered as an indication of recessive inheritance of malignant acanthosis nigricans. Family members of patients with malignant acanthosis nigricans were examined also for cancer without acanthosis nigricans. No specific trend with regard to frequency and location of tumors in the relatives of the 26 probands was seen, and cancer did not occur in the relatives of 14 (54%) of these probands. In 24 of the 26 probands with malignant acanthosis nigricans, the two parents in each case had an identical ethnic background. The possibility of a genetic basis for the whole syndrome of malignant acanthosis nigricans, as for part of it, has been discussed. The tumors associated with maligant acanthosis nigricans, although originating in various organs, show similar clinical behavior and similar morphology in that they all are adenocarcinomas; the specificity of these tumors, however, has not as yet been established. The percentage of gastric cancers among the cancers associated with malignant acanthosis nigricans has been high. The fact that no instance of transition from the benign to the malignant form or of occurrence of both types in one family has ever occurred confirms the assumption that benign and malignant acanthosis nigricans are separate diseases.

Fungistasis of Hydrocortisone and Certain of Its Analogues. R. L. Sauvan and R. L. Sutton Jr. A. M. A. Arch. Dermat. 79:53-54 (Jan.) 1959 [Chicago].

The authors tested the fungistatic properties in vitro of hydrocortisone acetate and hydrocortisone alcohol in 0.1 and 0.9% concentrations and of prednisolone phosphate and prednisolone alcohol in 1.0% concentrations. The organisms selected for testing were common dermatophytes: Trichophyton rubrum, T. gypseum, Microsporum audouini, M. canis, and Candida albicans. Results of the tests showed that the hydrocortisones and the prednisolones in the concentrations used did not display fungistatic properties against the fungi tested. C. albicans grew well under conditions adverse to the growth of T. gypseum, M. audouini, T. rubrum, and M. canis.

OTOLARYNGOLOGY

The Auditory Manifestations of Leukemia. E. Shanbrom and S. C. Finch. Yale J. Biol. & Med. 31:144-156 (Dec.) 1958 [New Haven, Conn.].

The records of the last 100 patients with leukemia admitted to the Yale-New Haven Medical Center were reviewed for evidence of acoustic difficulties. All patients with leukemia, irrespective of age, sex, and type of leukemia, were included. Thirty-two of the patients in this group had definite auditory signs or symptoms. In 16 there was a well-established relationship between the leukemia and the development of these disorders. In an additional 11 there was an almost certain but less definite relationship. There were 6 instances in which an otological complication presented as the only symptom or as part of the initial complaints which brought the patient to the hospital. Four of the 6 patients had acute leukemia. In the others the auditory difficulties developed in the course of the leukemia. In 5 of the 32 patients it was clear that the leukemia was not responsible for the auditory disorders. The most frequent auditory symptoms in the 27 patients were deafness in 16, tinnitus in 7, and pain in 3; only 1 patient complained of vertigo. A few patients were asymptomatic but had bleeding or purulent drainage from an external canal. The term "deafness" is employed to imply varying degrees of hearing loss.

The incidence of otological complications due to leukemia in this small series is 27%. Without the aid of histological examination it was difficult to be sure of the pathophysiology of some of the instances in which acoustic difficulties were encountered. In general, however, patients in whom hemorrhage was responsible usually had acute leukemia. Obstruction of the eustachian canals due to lymphoid hyperplasia was encountered only in chronic lymphocytic leukemia. Infection of the middle ear showed no predisposition to any particular type of leukemia. Auditory difficulties were commoner and developed earlier in patients with acute leukemia than in those with chronic leukemia.

Relief of Deafness by Stapes Mobilization. E. H. M. Foxen. Brit. M. J. 2:1558-1561 (Dec. 27) 1958 [London].

The author traces the history of stapes mobilization from 1875 when probably Kessel carried out the first mobilization. After a dormant period of half a century the operation was resurrected by Rosen in 1952. Stapes mobilization is most commonly indicated in cases of otosclerosis in which fenestration would have been advised formerly, and it is noteworthy that stapes mobilization is more general in its application than fenestration of the labyrinth. The diagnosis of otosclerosis should be firm and the hearing loss reasonably symmetrical. Pure-tone audiometry should ideally show a 35-to-55-db. loss of air conduction for the critical speech frequencies with a satisfactory air-borne gape (preferably at least 20 db.). Amplification should be well tolerated, paracusia present, and Schwartze's sign absent. Local analgesia is preferred but is not obligatory. After the incudostapedial joint and the surrounding anatomic structures have been displayed, maneuvers aimed at freeing the stapes are carried out. If mobilization is found to be impossible, fenestration of the stapes footplate is undertaken. The progress of the operation is controlled by hearing tests at intervals. Absorbable gelatin sponge (Gelfoam) provides a suitable dressing and may be retained by a strip of ribbon-gauze, which is removed after 2 to 4 days. As a rule, no particular sedation is required, and the patient is usually discharged on the 4th or the 5th postoperative day. Penicillin is given regularly during this time.

A comparison between features of stapes mobilization and fenestration shows that, when such matters as length of stay in the hospital and postoperative discomfort are considered, the magnitude of the former operation is much less than that of the latter. Results to date suggest that, of the patients undergoing stapes mobilization, about 33% may be expected to obtain a useful, lasting, and, in some cases, great hearing improvement; 33%, a slight improvement; and the remainder, no improvement. In a patient in whom the result is disappointing, the fact that the operation may have been performed several times does not preclude him from undergoing fenestration of the labyrinth at a later date.

THERAPEUTICS

Reversal of Intractable Cardiac Edema with Prednisone (Meticorten). D. A. Newman. J. Florida M. A. 45:778-782 (Jan.) 1959 [Jacksonville].

Ten patients with intractable cardiac edema were subjected to treatment with steroid preparations, principally prednisone. There were 7 men and 3 women, ranging in age from 60 to 85 years. All had arteriosclerotic heart disease, which was associated in 6 with hypertension; 5 of the patients had had myocardial infarction previously. Two patients had aortic regurgitation; 1 had pericardial calcification and constriction; 1 had diabetic glomerulosclerosis with the nephrotic syndrome; 3 had associated bronchopulmonary disease; and 1 had a recognized but quiescent duodenal ulcer. All these patients had been under treatment for congestive heart failure for 2 or more years. Since the standard therapeutic measures had been exhausted, they had become unresponsive to mercurials, to chlorothiazide, to aminophylline, and to such other treatments as induced hyperchloremic acidosis by the combined use of ammonium chloride and Diamox. These patients were considered as calculated risks and were treated accordingly with appropriate countermeasures.

Treatment with corticotropin (ACTH) was attempted in the first of the 10 patients in the series, but it proved a failure. A second patient who was treated with prednisone died after a cerebrovascular accident, but a good remission was obtained with this drug in the remaining 8 patients. The administration of prednisone was started in daily doses of 2.5 mg. This dosage was cautiously increased to between 15 and 20 mg. a day for 4 or 5 days and was then gradually decreased over a varying time interval, depending on each patient's response to the mercurial given after the priming with prednisone. With the onset of diuresis the daily maintenance dose varied from 2.5 to 10 mg. No other change in standard therapy for congestive heart failure was instituted. The intake of water and fluids was neither restricted nor enforced, except in 2 patients with hyponatremia; in the case of these patients a moderate restriction of fluids to 1 or 1.5 liters a day was recommended. Salt restriction was urged to a maximum of 1 Gm. per day. Ammonium chloride was given for one day before, one day during, and one day after the mercurials, when these were given by injection.

The most gratifying feature in the 8 patients who obtained remission with prednisone was the subsequent return of responsiveness to diuretics—not only to injection of mercurials in much smaller doses than previously but also to Diamox, to chlorothiazide, and even to the oral administration of Neohydrin. Diamox seemed to be unusually effective in the patients with additional bronchopulmonary disease and in the one with constrictive pericarditis. Five of the 8 patients have remained in good compensation for periods ranging from 9 to 28 months, but the other 3 have died. The first of these, a 76-year-old man with pericardial constriction and previous myocardial infarction, who had been in excellent compensation for more than 2 years on 2 tablets of Diamox a week and 2.5 to 5 mg. of prednisone a day, died suddenly of pulmonary embolism after he had discontinued this medication in favor of chlorothiazide without prednisone. The second patient died at the age of 74 years of an acute myocardial infarction 9 months after the initially successful reversal of the intractable cardiac failure. The third patient died at the age of 69 years of bronchopneumonia 14 months after a similar successful reversal. The intervening period of maintenance treatment had been most satisfactory as regards both relative comfort to the patient and general ease of management.

Clinical Evaluation of Povidone-Iodine Aerosol Spray in Surgical Practice. A. L. Garnes, E. Davidson, L. E. Taylor and others. Am. J. Surg. 97:49-53 (Jan.) 1959 [New York].

The authors used the complex of iodine and polyvinylpyrrolidone (povidone-iodine) in the form of an aerosol spray (Betadine Aerosol Spray) as an antiseptic and germicide in the preparation of 200 patients with lacerations for emergency suture, in the preparation of the skin in major surgical interventions on 100 patients, in the treatment of 16 patients with severe burns, and in the treatment of 15 patients with stasis ulcers of the leg. The wounds of all the patients with lacerations healed per primam without side-reactions or evidence of local irritation. Bacteriological cultures taken from the sites before and after operation indicated that all pathogenic agents were eliminated by wiping the skin dry and spraying the Betadine aerosol over an adequate surface; the only remaining organisms were saprophytes and diphtheroids. Biopsy of a skin specimen showed no penetration of the epidermal layers. Although most of the 100 patients subjected to major surgical procedures had established peritonitis or peritonitis due to spillage of intestinal contents, there were no wound infections in this group of patients and all operative incisions healed per primam.

In the patients with second-degree and third-degree burns, treated by spraying with the Betadine aerosol every 12 hours for the first 72 hours and daily thereafter until separation of the eschar began, the medication and method of application facilitated the open therapy of burns, providing a protective covering for areas denuded of skin. The antiseptic properties of the spray controlled infection and inhibited odor. Severely burned children found this form of treatment acceptable. In the patients with stasis ulcers, the lesions were sprayed twice or three times weekly with the Betadine aerosol, and compression bandages were applied. No side-reactions or satellite ulcers developed. The antiseptic agent aided in the maintenance of an environment ideally suited for healing. Even when it was applied to large, open wounds, discomfort was mild and transitory. Protein-bound iodine determinations did not reveal appreciable change in pretreatment and post-treatment levels. Providone-iodine spray is a safe, time-saving, effective antiseptic and germicide for surgical wounds, burns, and *stasis* ulcers.

Palliative Chemotherapy of Solid Tumors with Nitromin. R. G. Mrazek and S. G. Economou. A. M. A. Arch. Surg. *78*:51-55 (*Jan.*) 1959 [Chicago].

The authors report on 48 patients with various advanced malignant tumors who were treated with Nitromin at the tumor clinic of the Research and Educational Hospitals of the University of Illinois in Chicago. An average dose of 402 mg. was given, usually as 50 mg. per day. The drug was administered by the intravenous, intraperitoneal, or intrapleural route. Nitromin is an alkylating agent which was developed during the search for compounds which would have the therapeutic effect of nitrogen mustard with lessened toxicity. Of the 48 patients, 4 had malignant lymphoma, 5 had adenocarcinoma of the stomach, 8 had adenocarcinoma of the colon and rectum, 2 had adenocarcinoma of the pancreas, 4 had tumors of the kidney, 10 had bronchogenic carcinoma, 5 had squamous-cell carcinoma, 4 had malignant melanoma, 1 had carcinoma of the breast, and 5 had miscellaneous tumors. Two of the 4 patients with lymphoma showed reduction in fever and diminution in the size of the spleen and liver. Formation of pleural fluid was reduced in one patient with bronchogenic carcinoma and in one with metastatic adenocarcinoma of the thyroid gland. One patient with adenocarcinoma of the stomach with liver metastases had an improved sense of well-being, an increase in appetite, and relief of pain. These 5 patients obtained relief with relatively small total doses of Nitromin, 200 to 500 mg., whereas as much as 800 mg. was given to the other 43 patients with no effect; 24 of the latter are dead. Side-effects, such as nausea and vomiting, were frequently seen, but severe leukocyte depression was observed only in 3 patients. Nitromin did not cause local irritation or venous thrombosis.

The almost uniformly discouraging results in these patients with far-advanced carcinoma contrast completely with the well-documented demonstration that Nitromin can completely free rats of Yoshida ascites sarcoma implants, if given when the tumors are still small. The authors agree with Ishidate and Druckrey that Nitromin might be effective in patients with tumors in the early stages, or when administered in combination with surgical treatment to destroy microscopic tumor remainders, or when given intravenously after operation to destroy free cells in the blood. Nitromin has the advantages of low toxicity, ease of injection, and relative freedom from side-effects.

Chlorothiazide (Chlotride) in Edema: Clinical Tests with a Mercurial Diuretic. D. Jensen and H. S. Mathisen. Tidsskr. norske lægefor 78:1166-1170 (Dec. 1) 1958 (In Norwegian) [Oslo].

Twenty-eight patients (average age, 68½ years) were treated with chlorothiazide for from 3 to 9 days because of edema. In all, 61 treatments were given. The chlorothiazide dose was usually 0.50 Gm. daily, i. e., ½ tablet twice daily, preferably in the morning and at noon; in 5 tests 1 Gm. was given daily, in 2 cases the dose was reduced to 0.25 Gm. daily. The average increase in diuresis was about 70% daily; the average loss of weight during the time of treatment was 0.31 kg. (¾ lb.) daily. The maximal increase in diuresis averaged 143%, with variations between 29 and 323% in the different periods of treatment. The authors found that chlorothiazide seems to approach the ideal diuretic. It was in several tests equal to or superior to mersalyl and better than other diuretics tried for oral use. With the dosage applied, the agent was practically free from side-effects.

Pathological and Biochemical Considerations on Chronic Alcoholism with Relationship to the Therapeutic Effect of Liver Extracts Administered Intravenously. P. Benassi and D. Munarini. Minerva med. 49:4334-4341 (Nov. 24) 1958 (In Italian) [Turin, Italy].

Intravenous administration of Ripason, an Italian proprietary liver-extract preparation, had a beneficial effect on 30 chronic alcoholic patients. Before the treatment the tolerance of each patient was tested by parenteral administration of 1 cc. of this liver extract; during treatment the patient received a daily dose of 3 or 4 cc. The preparation was always introduced into the vein with some rapidity. Twenty patients were treated for 30 days and 10 patients for 60. The drug was well tolerated and did not cause undesirable side-effects during or after its injection. Clinically, an improvement, at times very marked, of the general condition and of the metabolism followed in all the patients; the appetite increased and the cenesthesia improved markedly. Psychologically, the preparation had a beneficial antidepressive effect on the adjustment of the patients to the environment, and caused improvement in their daily work and general behavior. The group of patients who received treatment for 2 consecutive months showed improvement in the Takata, Wuhrman-Wunderly, and Kunkel laboratory tests.

A New Treatment for Cutaneous Larva Migrans: Employing Oral Promethazine. J. L. Greene. J. Florida M. A. 45:784-788 (Jan.) 1959 [Jacksonville].

The oral administration of promethazine (Phenergan) hydrochloride to 57 patients with creeping eruption caused by larva migrans is reported. The group included both sexes and ranged in age from 14 months to 68 years. The patients presented skin lesions on various parts of the body, but the extremities, the back, and the perineum were more frequently involved. The compound was administered at bedtime—as a sirup to children up to the age of 6 years in doses of 50 mg. and as tablets to older children in doses of from 75 to 100 mg.; adults were given oral doses of 150 mg. or more. The same doses were given on 3 successive nights, and occasionally it was necessary to repeat the course with the same amount or with an increased dosage.

The oral administration of promethazine was a failure in the first 6 patients (10.5%) who were given only small doses (25 mg.) of the drug. The pruritus, however, promptly disappeared in all the remaining patients (89.5%) after the first larger doses of promethazine were given; at the same time the marked redness and the prominence of the skin lesions began to fade, and healing was complete within 3 or 4 days. The soporific properties of promethazine, which are entirely separate from the activity of the compound upon the larva, were an advantage to these patients, since insomnia caused by intense itching is one of the consequences of cutaneous larval infestation. The hyperexcitability exhibited by some patients after the ingestion of the first dose of this compound may be promptly controlled by an additional dose, and this reaction does not represent a contraindication to the use of the compound. The success obtained solely by the oral administration of promethazine is of great interest, since all treatments so far suggested for cutaneous larva migrans have been disappointing.

Absorption of Orally Administered Vitamin B_{12} in Pernicious Anaemia. J. N. M. Chalmers and N. K. Shinton. Lancet 2:1298-1302 (Dec. 20) 1958 [London].

Fifteen men and 6 women, between the ages of 43 and 82 years, with pernicious anemia in relapse were treated for 15 days with daily doses of vitamin B_{12} given orally alone. The amount of vitamin B_{12} given ranged from 20 to 500 mcg. daily. The larger the daily dose of vitamin B_{12} given orally, the more prompt was the hematological response and the return of the serum vitamin B_{12} level to the normal range. Long-term maintenance therapy with daily doses of vitamin B_{12} was given orally to 12 patients, 3 of whom received doses of 50 mcg. daily for periods ranging from 21 to 50 months, 3 received doses of 100 mcg., 2 received doses of 200 mcg., and 4 received doses of 500 mcg. daily for periods ranging from 6 to 26 months. Results showed that daily doses of 100 mcg. or more of vitamin B_{12} given orally can be effective in maintenance therapy. These findings provide further proof that vitamin B_{12} given orally can be absorbed and utilized by patients with pernicious anemia. Some of the patients obtained normal hematological values and clinical remissions without return of serum vitamin B_{12} level to normal. Parenteral therapy with vitamin B_{12} is still the most reliable method of ensuring freedom from relapse in pernicious anemia, but with the close cooperation of the patient oral treatment by daily application may be effective.

Vitamin B_{12} in Pernicious Anemia: Intramuscular or Oral? E. H. Hemsted and J. Mills. Lancet 2:1302-1303 (Dec. 20) 1958 [London].

The authors compared the effects of oral and intramuscular administration of vitamin B_{12} in patients with pernicious anemia treated at the Royal Berkshire Hospital in Reading, England. Over a period of 2 years a group of 71 patients taking a daily dose of 100 mcg. by mouth one hour before breakfast were maintained at least as well as a group of 84 patients receiving a monthly intramuscular injection of 100 mcg. Thirty-four patients with pernicious anemia were treated for 2 years with intramuscular injections of 1,000 mcg. of vitamin B_{12} per month; there was no significant change in hemoglobin and red blood cell levels, and, therefore, no advantage in a higher dose than 100 mcg. per month for maintenance treatment was apparent.

PATHOLOGY

Coccidioidal Pulmonary Cavitation. L. Hyde. Am. J. Med. 25:890-897 (Dec.) 1958 [New York].

The author reports on 76 men and 1 woman with coccidioidal pulmonary cavitation, 57 of whom were studied at the Veterans Administration Hospital in Long Beach, Calif., and 20 were included in the Veterans Administration–Armed Forces Cooperative Study of Coccidioidomycosis. The median age was 25 years; 90% were under 40 years of age. Coccidioidal pulmonary cavitation occurred in 2 or 3% of those patients in whom primary infection due to Coccidioides immitis was severe enough to cause consultation of a physician. Fifty-eight per cent of the whole group were essentially asymptomatic, and the condition was detected on the taking of routine chest roentgenograms; 26% were subjected to roentgenography because of hemoptysis, 6% because of chest pain, and 10% because of acute respiratory symptoms. In most of the patients who gave a history of bleeding, there had been only minimal blood streaking or a small hemoptysis. Cavitation in this disease occurs at the site of the original coccidioidal pneumonia. Generally there are no signs or symptoms during the process of cavitation in hospitalized patients. Eighty-six per cent of the 77 patients in this series had a single cavity, and 14% had multiple cavities. Fifty-eight per cent of the cavities were in the right lung, and 42% in the left lung; 3 patients had bilateral cavities. The results of the coccidioidin skin test were positive in 57% of the 73 patients for whom the results were recorded. In most cases the skin test was made once, but for some it was repeated on numerous occasions. Sixty-four per cent of the 77 patients had positive complement-fixation antibodies in varying degrees.

Nonsurgical and surgical treatment in patients with coccidioidal pulmonary cavitation has been compared. Forty-six per cent of the whole group were treated nonsurgically. Most patients were asymptomatic, but 22% of this group had a history of bleeding; no new cavities developed in any of the 36 patients. Fifty-four per cent of the 77 patients underwent resectional surgery. Twenty-nine of these patients were asymptomatic, although 30% gave a history of bleeding. There were no deaths, but in 29% of the patients who had resection, bronchopleural fistulas with empyema developed, and 20 additional surgical procedures were required. Furthermore, new cavities appeared postoperatively in 20% of the patients who underwent resection. On the basis of these findings a conservative nonsurgical treatment appears most desirable for patients with coccidioidal pulmonary cavitation, unless the cavity is more than 4 cm. in diameter or is enlarging significantly or there have been recurrences of severe hemoptysis.

Incidence and Prognosis in Cancer of the Rectum in a Danish Provincial Town. N. Blixenkrone-Møller. Danish M. Bull. 5:268-272 (Dec.) 1958 (In English) [Copenhagen].

From 1946 to 1955, 180 cases of rectal cancer, in 112 men and 68 women, were diagnosed in Aarhus (population of about 113,000). In all but 10 cases the diagnosis was confirmed by histological examination; in 6 of the 10 there were metastases, and 4 were clinically unquestionable. Most cases occurred between the ages of 60 and 70 years. Up to the age of 60, cancer of the rectum is equally frequent in men and women; a steep rise then occurs among men. The lower margin of all tumors was at a level of 20 cm. or less from the anus at proctoscopic examination. Of the 170 cases examined histologically, 158 were adenocarcinomas; 6, solid carcinomas; 5, malignant papillomas, with typical invasive growth; and 1, a lymphosarcoma. Diagnosis was made within the first 3 months after the onset of the first symptom in only 42% of the cases. About 30% of the cases were radically inoperable. Major radical operation was performed on 98 of the patients with radically operable cancer. Of these, 37% were living 5 years later, or, corrected for deaths from unrelated causes, 43%. Of the entire group of 180 patients, only 20% were living after 5 years. A few had died of causes other than cancer. The prognosis is better for the age group under 60. There was no demonstrable difference in the prognosis for men and for women. The analysis shows that removal of skin and pelvic connective tissue must be more radical.

Fat Embolism in Chronic Alcoholism: Control Study on Incidence of Fat Embolism. M. J. G. Lynch, S. S. Raphael and T. P. Dixon. A. M. A. Arch. Path. 67:68-80 (Jan.) 1959 [Chicago].

The changes found in the central nervous system in association with chronic alcoholism appear to be ill-defined. Wernicke's "superior hemorrhagic polioencephalitis" was specifically linked to chronic alcoholism, and Gudden's atrophy of the corpora mammillaria was somewhat later similarly associated; however, subsequent observations cast much doubt on the specificity of the association between the Wernicke-Gudden changes and alcohol addiction. It is now accepted that the lesions described by these pioneers are due to concomitant vitamin deficiencies. Although general dietary improvement has altered the neuropathological picture of chronic alcoholism, certain diffuse or patchy, ill-defined, and apparently nonspecific changes, such as loss of neurons, focal degenerative lesions, atrophy, and astrocytic proliferation, remain to be explained.

The interest of the present authors in this problem was aroused by the work of Hartroft and Ridout, who demonstrated that in rats fed on choline-deficient diets "fat cysts" develop in the livers and that such large fat globules may rupture into biliary or vascular channels. These workers examined human autopsy material from 30 cases of chronic alcoholism and found "small amounts of embolic fat within the vessels of the lungs and kidneys in a number of cases." In preliminary studies on 250 consecutive autopsies, the present authors found fat embolism only in cases of trauma, alcoholic fatty liver, and necrotizing pancreatitis. However, in that series only one block each from lung and kidney was examined, and these were not uniformly selected as to size or site. For the present investigation a more thorough study was planned, and a block from each lung was selected and examined.

From the beginning of 1957 to the present time the authors have made studies on 51 patients with alcoholic psychosis admitted to their psychiatric unit. Morning sputum samples were examined for fat droplets, which were found in 48 of them. The 3 patients with sputums which were negative for fat globules had little more than "hangovers." The authors conclude that fat embolism is of common occurrence in chronic alcoholics. Fat embolism is advanced as a major factor in the etiology of alcoholic psychoses and may lead to death in some such cases. Repeated fat embolism may be the basis of some, at least, of the changes noted in the brains of chronic alcoholics.

Rheumatic Pneumonitis: Pathological Features. R. F. Scott, W. A. Thomas and J. M. Kissane. J. Pediat. 54:60-67 (Jan.) 1959 [St. Louis].

Autopsy was performed on 87 children, ranging in age from 3 to 16 years, who died of pneumonitis due to rheumatic fever during 1919-1954 at the St. Louis Children's Hospital. Microsections of the lungs were examined especially for fibrinous exudate in the alveolar sacs or respiratory ducts, hyaline-like membrane, and necrosis of the alveolar walls and thrombi. Pathological changes were graded as "slight" if less than 10% of the tissue available for miscroscopic study was estimated to be involved, "moderate" if 10 to 20%, and "advanced" if more than 20%. With this criterion, 21 cases (39%) showed slight pathological change; 29 (54%), moderate change; and 4 (7%), advanced change. The cases were divided into 3 age groups—3 to 5 years, 6 to 10 years, and 11 to 16 years. The incidence of rheumatic pneumonitis in each group was as follows: 8 of 11 cases (73%) in the youngest group; 24 of 32 cases (75%) in the intermediate group; and 24 of 44 cases (55%) in the eldest group. Gross findings were not distinctive. Most anatomic specimens revealed only congestion and edema; only occasionally were there grayish-red and firm lungs which exuded little fluid and were suggestive of rheumatic pneumonitis. Histologically, the most characteristic feature was a patchy, dense, fibrinous exudate in the alveolar sacs and in the respiratory ducts. This exudate was in the form of irregular globular masses or membranes and was almost invariably associated with monocytes (many containing hemosiderin) and protein-rich edema fluid. Intra-alveolar hemorrhage was common. No consistent difference was found between the anatomic features -seen in pneumonitis due to rheumatic fever and those in pneumonia associated with other diseases.

Histomorphologic Study of the Changes of Arterial Walls from Birth Until the Age of Twenty, with Particular Reference to the Coronary Arteries. M. Bisiani. Minerva cardioangiol. 6:519-536 (Oct.) 1958 (In Italian) [Turin, Italy].

Histological examination of the walls of the sylvian arteries, of the aorta, of the anterior descending coronary artery, and of a section of renal arteries was made in 56 patients. There were 33 males and 23 females, aged between birth and 20 years. These patients had died of an acute disease, such as acute enterocolitis or acute appendicitis, and none of them had a posthumously observed lesion of a more remote disease. Histological changes and the rate of thickening with age of the aorta and of the sylvian and renal arteries in these patients were gradual and similar, whereas those of the coronary arteries were dissimilar to the changes observed by other workers. The structure of the intima of the coronary arteries started to change after a few weeks of life, while the tunica media and the adventitia appeared normal. At the age of 3 or 4 months a sectional thickening of the subendothelial connective tissue of the coronary arteries was observed in both sexes. Various processes took place in the intima, involving edematous imbibition of the subendothelial mesenchyma, neoformation of elastic fibers, thickening and splitting of internal elastic membranes, and formation of fibroblastic cells, histiocytes, and lymphoids. Endothelial cells also seemed to participate in these precocious changes, exhibiting mild regressive processes. The intima thickened, and gradually larger sections of it became affected with age. After the first decade of life, thickening of the subendothelial mesenchyma involved the whole intima, which was in some sections thicker than the tunica media. The hyperplastic process apparently did not affect the tunica media and only slightly the adventitia. Lipids started to appear when thickening of the intima reached or surpassed that of the tunica media.

Pseudomonas Septicemia: Observations on Twenty-three Cases. C. E. Forkner Jr., E. Frei, J. H. Edgcomb and J. P. Utz. Am. J. Med. 25:877-889 (Dec.) 1958 [New York].

The authors report on 23 patients with malignant neoplastic disease (13 of these patients had acute leukemia, 1 had acute disseminated histoplasmosis, and 1 had mycosis fungoides). In addition, these patients, who were seen at the clinical center of the National Institutes of Health in Bethesda, Md., between 1954 and 1957, had the complication of septicemia due to Pseudomonas organisms. The common clinical manifestations of Pseudomonas septicemia include characteristic cutaneous lesions, progressive jaundice, neurological abnormalities, arrhythmia, ileus, and sudden development of hypotension. Twenty-two of the 23 cases were fatal. The median duration of life after identification of the first positive blood culture was 4 days. The most striking gross and morphologic changes were the cutaneous lesions, which were classified according to the following 4 categories: (1) ecthyma gangrenosum, which mostly occurred in the anogenital area; (2) vesicular lesions, which tended to occur in clusters; (3) flat and sharply demarcated cellulitis, which after rapid enlargement became hemorrhagic and necrotic; and (4) small, pink, round maculopapular plaques or nodules, characteristically found on the trunk. In the course of Pseudomonas septicemia metastatic abscesses may appear in any part of the body. The affinity of Pseudomonas organisms for the walls of small vessels is stressed.

Of the 23 patients in this series, the 13 with acute leukemia were selected, as a group, for the analysis of epidemiology and host resistance. Pseudomonas aeruginosa was the second most frequent cause of septicemia and the most frequent bacterial cause of death on the acute leukemia service. The cases of Pseudomonas septicemia on the acute leukemia service were noted to occur in groups, in contrast to the random distribution of other bacterial septicemias occurring on that service. Gram-negative septicemias occurred more frequently than septicemias due to gram-positive bacteria in patients receiving adrenal steroid therapy. Of the 13 incidences of Pseudomonas septicemia, 10 occurred in patients receiving broad-spectrum antimicrobial therapy, whereas the respective figure for other gram-negative septicemias was only 12 of 22 incidences, and for gram-positive infections only 13 of 39 incidences. These data add to the evidence that Ps. aeruginosa is a common super-infecting organism. There is suggestive evidence that antimetabolite administration may in some way predispose to the development of Pseudomonas septicemia.

Familial True Hermaphrodism in Pre- and Postpuberal Genetic Females: Hormonal and Morphologic Studies. G. W. Clayton, J. D. Smith and H. S. Rosenberg. J. Clin. Endocrinol. 18:1349-1358 (Dec.) 1958 [Springfield, Ill.].

Two siblings with scrotal testes and ovaries are presented. The first, aged 16 years, except for a congenital abnormality of the penis described as "complete hypospadias without cryptorchidism," which had been successfully repaired at age 4, appeared to be a psychologically well-orientated male. Concomitant with the normal puberal changes —growth spurt, increase in size of the penis, appearance of sexual hair, and deepening of the voice, there had been progressive enlargement of the breasts. In retrospect the testes were noted to have remained small and insensitive. The family history was significant in that a 7-year-old brother had a similar congenital abnormality of the external genitalia. A 12-year-old brother was normal. A smear of the buccal mucosa in the 16-year-old sibling demonstrated a positive nuclear chromatic pattern, but urethrograms failed to reveal vestiges of the Müllerian system. Hormonal studies showed a low urinary excretion of 17-ketosteroids, an elevated excretion of estrogens and pregnanediol, and a normal excretion of gonadotropins. The initial impression was Klinefelter's syndrome; however, the familial hypospadias suggested that a more complex type of gonadal dysgenesis existed.

The second sibling, now aged 7 years, had been born prematurely. The infant had been considered normal except for a defect in the external genitalia. A phallus of normal size was bound down ventrally and lacked a urethral meatus. Urine was emitted through a small opening at the base of the phallus. The normal-appearing scrotum contained palpable gonads. An abdominal exploration carried out in infancy revealed no female internal genitalia. The construction of a penile urethra was completed at the age of 6 years. At 7 years the boy was of normal height and weight. The penis was slightly hooded at the base with a fold of skin, but otherwise appeared normal except for old operative scars on the ventral surface. The scrotum contained small, very mobile gonads of normal consistency. This child also had a positive nuclear chromatin pattern in the buccal smears, and a urethrogram showed that there were no Müllerian vestiges. Studies of urine samples revealed a normal excretion of 17-ketosteroids and estrogens, a slightly elevated excretion of pregnanediol, and a gonadotropin excretion of less than 6 mouse units.

The scrotal contents were explored in both siblings. The testes of the postpuberal sibling showed seminiferous tubule dysgenesis which was identical to that found in Klinefelter's syndrome, whereas the testes of the prepuberal sibling were histologically normal. Sections of the 1-cm. oval mass from the upper pole of the right testis in the first sibling revealed ovarian tissue, consisting almost entirely of stromal elements in which a few scattered primordial and atretic follicles were identified. In the epididymis there was a tubular structure, lined by a pseudostratified columnar ciliated epithelium; this structure was presumably a vestigial fallopian tube. In the 7-year-old sibling a section of ovary sat cap-like on each testis. Within the ovary there was abundant stroma with numerous peripherally placed primordial follicles. Peripheral clumping of nuclear chromatin, characteristic of the female, was demonstrable in many Leydig cells in the testes of the first sibling and in the seminiferous tubule cells of the second sibling. As far as the authors know, this is the first reported instance of familial true hermaphrodism. In an addendum they call attention to a recent report on 2 siblings with true hermaphrodism in whom the chromatin pattern was negative.

Further Observations on Infection with Phage Type 80 Staphylococci in Australia. P. M. Rountree and M. A. Beard. M. J. Australia 2:789-795 (Dec. 13) 1958 [Sydney].

In 1953 a new phage type of Staphylococcus pyogenes var. aureus was isolated from infections of newborn infants in a Sydney maternity hospital. Later it was found that this particular strain, which had been given the phage type designation 80, had been responsible for a large proportion of outbreaks of neonatal infection in hospitals throughout Australia during 1954, and that it had become established as a cause of cross infection in adult patients at the Royal Prince Alfred Hospital, Sydney, where it had also caused an epidemic of boils in the staff. In 1955 and 1956 investigators found that the majority of penicillin-resistant staphylococci isolated from boils in Sydney belonged to this type. Apparently the same type of Staphylococcus organism was observed in Canada, and it was identified with phage type 81. The 2 phages, 80 and 81, are not identical, but their propagating strains are lysed by both phages and can be regarded as identical; their typing pattern is, therefore, 80/81. Other strains occur which are lysed only by phage 80 or only by phage 81, but these are much rarer. Strains of phage pattern 80/81 have been isolated in many parts of the world and have been responsible for much serious staphylococcic sepsis.

The authors report their observations during the 3 years that have elapsed since their first report. The data presented in this paper justify the view that much of the morbidity due to Staph. aureus occurring in Australia in the past 4 years has been caused by strains of phage type 80/81. Staphylococci of this phage type were responsible for 70 of 86 major outbreaks of staphylococcic infection among newborn infants in Australia from 1954 to the end of 1957. They predominated in serious infections in infants and older children admitted to children's hospitals in Sydney. At the Royal Prince Alfred Hospital since 1955 they have been the predominant, but not the only, staphylococci found in cross infection in patients, and they have been the chief cause of staphylococcic lesions in the nursing and medical staffs. Strains of this type are now widespread in communities outside the hospitals. A marked increase in the incidence of generalized staphylococcic infection in 1956 and 1957 was due almost entirely to them. In 9 out of 12 cases of fulminating staphylococcic pneumonia associated with Asian influenza in 1957, strains of this type were the infecting organisms. Nearly all the strains of this type are penicillin resistant, but so far resistance to other antibodies is more limited in extent.

Reaction of Lupus Erythematosus Serum with Nuclei of Circulating and Non-Circulating Cells. W. R. M. Alexander and J. J. R. Duthie. Brit. M. J. 2:1565-1566 (Dec. 27) 1958 [London].

Experiments carried out by other workers showed that tissue cells brought in contact with serum obtained from patients with disseminated lupus erythematosus and exposed subsequently to fluorescein-conjugated anti-human-globulin (Coombs's) serum showed specific nuclear fluorescence, thus providing strong evidence for the belief that the serum of patients with disseminated lupus erythematosus contains a globulin which combines with nuclei of tissue cells and leukocytes. The authors studied the serums obtained from 8 patients with disseminated lupus erythematosus and observed that nuclei of leukocytes from healthy persons showed the greatest affinity for the specific globulin. No evidence of uptake of globulin in tissue from patients with disseminated lupus erythematosus was found in vivo, but in vitro such tissue had less affinity for the specific globulin than tissue from healthy subjects. Nuclei of intact squamous epithelial cells pretreated with serum obtained from the patients with disseminated lupus erythematosus did not fluoresce on exposure to fluorescein-conjugated anti-human-globulin serum.

Cultivation of Human Breast Carcinomas. E. Y. Lasfargues and L. Ozzello. J. Nat. Cancer Inst. 21:1131-1148 (Dec.) 1958 [Washington, D. C.].

Although most of the human carcinomas have been successfully transplanted in vitro, the mammary carcinoma has remained a challenge for the investigator. The authors discuss some of the technical difficulties encountered in earlier reported attempts at explantation and growth of neoplastic tissues from human breasts. Recent progress in research on the mouse mammary carcinomas makes it imperative to grow human breast tumors for comparative studies. Since viral induction of these neoplasms in the mouse has gained more support, the availability of human tissue-culture material for experimental purposes could be enlightening, and valuable information might be obtained from its use in screening techniques for therapeutic agents.

The authors have developed a technique for the cultivation of human breast carcinoma cells, which in taking advantage of the weak intercellular bonds within the tumor harvests the cells "spilling" out of the tumor stroma when thin slices are cut with a razor blade. This suspension is sensitive to customary enzymatic concentrations which, therefore, cannot be used in the preliminary step of preparation. Agitation, even the slow motion of the roller drum, is unfavorable to the growth of the neoplastic cells; they have to be explanted in resting tubes.

Continuous cultivation of human breast carcinoma cells has thus been achieved for the first time. The cultures, derived from a mammary-duct-cell carcinoma of no special type, are now in their 6th month of life in vitro and are extremely proliferative. The regular growth rate of the neoplastic cells appears to be dependent on the presence in the medium of mucopolysaccharides introduced in the form of umbilical cord extract. Human placental serum and beef amniotic fluid, whose high content in estrogenic hormones is well known, also have a beneficial effect. Folic acid in a 2.5 mM.

concentration appears favorable to the growth of the cancer cells. However, a possible antagonism with cord extract has been considered in the spindle-shaped transformation which occurs in the epithelial cells when transferred from a folic acid medium to one enriched with umbilical cord extract.

The authors feel that the above-mentioned changes should be kept in mind in relation to the spindle-cell type of carcinomas occasionally observed by pathologists and to the spontaneous sarcomatous transformations of experimental carcinomas reported in the current literature. In an addendum they state that the fibroblast-like cells have again reverted to their original epithelial morphology. Such modifications, therefore, are determined by variations in the environmental factors and are reversible.

RADIOLOGY

Roentgenographic Study of the Progress of Osseous Metastases of Mammary Carcinoma After Bilateral Ovarioadrenalectomy. A. M. Dogliotti, A. Ruffo, F. Badellino and others. Minerva chir. 13:1213-1225 (Oct. 31) 1958 (In Italian) [Turin, Italy].

The authors report on roentgenologic findings of osseous metastases in 10 patients who underwent a bilateral ovarioadrenalectomy because of mammary carcinoma in an advanced phase. Eight patients died within a period of from 5 to 30 months after the operation. Improvement or deterioration of osseous metastases after operation was more tardily observed by roentgenograms than by clinical means. Cortisone therapy produced improvement in subjective symptoms and in state of health in only a few patients, although roentgenograms demonstrated severe lesions of osseous metastases. Roentgenograms and clinical findings may be dissimilar at particular periods of observation in these patients after operation, but the 2 methods complement each other in the over-all picture. Pictures of osteolytic foci and zones of recalcification, representing simultaneous processes of both bone destructive activities and of reossification, were observed in several patients. Clinical and biochemical findings determined which one of the 2 processes predominated. Periodic roentgenologic inspections of the whole skeleton can be used as a collateral, although tardy, procedure in evaluating the efficacy of bilateral ovarioadrenalectomy in patients with advanced mammary carcinoma. Laboratory investigation of calcemia and phosphatemia was a third procedure used in this series of patients. It can be particularly useful in discovering osseous metastases in those instances in which clinical and roentgenologic findings are negative. Simultaneous application of clinical, roentgenographic, and laboratory investigations seems to be the best method for observing the progress of osseous metastases in patients who have undergone bilateral ovarioadrenalectomy for advanced mammary carcinoma.

Thyroid Cancer in Youth. D. W. Petit, B. Catz and P. Starr. California Med. 89:394-396 (Dec.) 1958 [San Francisco].

The authors report on 9 boys and 2 girls with cancer of the thyroid, whose ages ranged from 5 to 18 years at the time the diagnosis was made. In 8 of the 11 patients the diagnosis was suggested by persistent enlargement of the cervical lymph nodes. Seven patients were subjected to total thyroidectomy, 3 underwent hemithyroidectomy, and 1 had repeated removal of lymph nodes in the neck, only one of which was cancerous. After total ablation of normal thyroid tissue and removal of as much malignant tissue as possible surgically, scintigram and/or radioautograph studies with radioiodine (I^{131}), administered in doses of 1/10th to 10 mc., were carried out in 9 of the 11 patients. In 6 of the 9 patients uptake of the radioactive material was demonstrated. These 6 patients then were treated with I^{131}, a dose of 100 mc. being given by mouth. Administration of the radioactive agent was continued, with interval studies in which millicurie doses were used for tracer purposes only until no further uptake was observed. During this whole period the patients were kept in a euthyroid state by the administration of thyroid hormone or levothyroxine. The patients were followed up for periods ranging from 10 months to 9 years. Of the 11 patients, 9 were free of metastases as nearly as could be determined. One patient had metastatic pulmonary lesions that were not shown to take up I^{131} and that progressed despite the administration of a total dose of 250 mc. of I^{131}. Another patient had questionable pulmonary metastasis.

Nine of the 11 patients had had roentgenotherapy to the head or neck previous to the diagnosis of thyroid cancer. Other workers had reached the tentative conclusion that irradiation is possibly carcinogenic to the normal preadolescent when given in therapeutic amounts. In 2 previously reported series of thyroid cancer in children, 10 of 28 patients in one and 15 of 15 patients in the other had had roentgen-ray treatment to the head and neck before the cancer was diagnosed. As yet, there have been no surveys that would establish the incidence of head-and-neck irradiation in a population of the kind represented by the authors' patients, but the significance of the reported observations would depend on the incidence. Inasmuch as the ultimate answer to the problem of such irradiation as a possible stimulus to the production of thyroid cancer is not yet at hand, it would seem prudent to avoid, if possible, therapeutic irradiation to the head and neck of preadolescent children with a normal thyroid gland.

Operative Cholangiography in the Diagnosis of Prolonged Jaundice in Infancy. J. H. Harris Jr., A. E. O'Hara and C. E. Koop. Radiology 71:806-815 (Dec.) 1958 [Syracuse, N. Y.].

Whereas in many institutions operative cholangiography is a routine procedure during biliary tract surgery in adult patients, the value of delineating the biliary ductal system in pediatric surgery is not generally realized. The authors describe the technique of operative cholangiography that is being used at the Children's Hospital of Philadelphia. The peritoneal cavity is entered through a small right subcostal incision, and the gallbladder is identified. If the latter is of normal size and contains normal appearing bile, a patent communication between the gallbladder and the liver may be assumed, but this does not reflect the caliber of the communication. Furthermore, this does not aid in the differentiation between the "inspissated bile syndrome," viral hepatitis, and atresia of the common bile duct. A mushroom catheter is inserted into the gallbladder through a small cholecystostomy, and held in place with a purse-string suture. After irrigation of the biliary ductal system to eliminate artefacts caused by bile plugs, 8 to 20 cc. of 15% Urokon is injected through the catheter. It is important that the patient be apneic during the x-ray exposure, and that the exposure be made after approximately 80 to 85% of the contrast medium has been introduced. The authors attempt to obtain a right posterior oblique projection in order to avoid superimposition of the ductal structures and to project them away from the spinal column. If the cholangiographic findings indicate a normal biliary ductal system with free flow of the contrast medium into the duodenum, a liver specimen is taken for biopsy, and the abdomen is closed. If, on the other hand, there is roentgenologic evidence of atresia of the ductal system, the initial incision is extended to allow adequate exposure for exploration of the porta of the liver.

Since 1953 operative cholangiography has been employed in 12 instances. Three infants were 1 month of age; the oldest child was 21 months old. Of the 12 patients, 6 were found to have normal extrahepatic ductal systems, 1 had atresia of the common bile duct, and 4 had congenital atresia of the hepatic ducts. The histories of 4 of the children are described in detail. In one of these no contrast medium was seen in the common hepatic duct or its radicals, and the roentgenogram was interpreted as representing atresia of this portion of the ductal system. However, when the cholecystostomy was done, normal bile was found in the gallbladder, and because of this the roentgenologic findings were considered to be falsely indicative of biliary atresia. The liver biopsy specimen, taken at the time of laparotomy, revealed hepatitis. In each of the other 11 cases, the operative cholangiographic findings helped the surgeon. When a normal biliary tree was outlined, the abdomen was closed. The surgical procedure was thereby shortened, reducing both the surgical trauma and the exposure of the already embarrassed liver to anesthetic agents. In addition, since only the gallbladder was involved in the surgical dissection, the possibility of postoperative fibrosis about the normal infantile ducts was avoided.

The causes of jaundice in newborn and older infants are icterus neonatorum, congenital hemolytic jaundice, erythroblastosis fetalis, syphilitic hepatitis, jaundice due to sepsis, intrauterine viral hepatitis, and congenital atresia of the bile ducts. Uncorrected atresia of the bile ducts is not compatible with long life, although many patients survive for some years. The early clinical picture is that of a jaundiced child with dark urine and acholic stools. Recent work tends to implicate the virus of homologous serum hepatitis in acquired biliary atresia. The fact that biliary atresia is the most frequent cause of obstructive jaundice in infancy, that in its unaltered course the disease is fatal, and that only early surgical correction can prevent the cirrhotic process emphasizes the importance of early limited exploration and study of the biliary ductal system by operative cholangiography.

Undulant Fever Spondylitis. F. Zammit. Brit. J. Radiol. 31:683-690 (Dec.) 1958 [London].

Undulant fever caused by Brucella melitensis is endemic in Malta and causes much disability. Diagnosis is difficult during its early stages. The blood should be tested for the agglutination reaction. A serum agglutination reaction of 1:80 is regarded as diagnostic, but in some cases the reaction does not rise above 1:40. A rising titer is indicative of active brucellosis. Blood culture is not always positive. Bone marrow examination may help in the diagnosis, especially when it is drawn from the sites which show roentgenologic signs of bone involvement. The main symptom of this disease is a highly irregular fever, with the temperature rising and falling, which goes on for long periods and is often associated with headaches, enlargement of the spleen, excessive perspiration, secondary anemia, weakness, and pains of a rheumatic type. The commonest sites of these rheumatic pains are the neck, shoulder, lumbar region, hip, thigh, and knees.

The author reviewed all the cases diagnosed as brucellar spondylitis in the orthopedic department of a hospital in Malta from 1947 to 1954. During this period spondylitis was diagnosed in 115 of 6,301 patients with undulant fever. In a typical case the signs and symptoms of spondylitis manifested themselves during the period of convalescence from brucellosis. The earliest and most constant symptom was pain, localized to the affected region of the spine. It was made worse by movements and was relieved by rest. Referred pains to the limbs, and in some cases the girdle type, occurred. Spasm of the spinal muscles was commonly present. In 62 of the patients roentgenologic evidence of spine involvement was found; the regional distribution was as follows: cervical, 5; thoracic, 16; combined thoracic and lumbar, 4; and lumbar, 37. The 4th lumbar vertebra was most commonly involved. The main changes were destructive lesions in the vertebral bodies, usually marginal, with characteristic sclerotic reactions around them and proliferative marginal new bone formations resembling calcifications of ligaments or osteophytic processes. The disk space was usually narrowed. Signs of cord compression were present in 8 patients. The following conditions have to be differentiated from brucellar spondylitis: Pott's disease, staphylococcic osteomylitis, actinomycosis, osteochondrosis of the vertebrae, and osteoarthritis.

Treatment is largely conservative; in recent years antibiotics have been administered with favorable results. The author found that most patients derived benefit from rest in bed or on a Bradford frame. When root pains, with radiation to the upper and lower limbs, were present, traction was applied, and the patient was eventually relieved. When the condition of the patient improved and the pain abated or disappeared, a plaster jacket was applied. Recovery took place after several months, depending on the extent of the lesion, and in the majority of cases the patient returned to his former work. The period of disability varied from 3 to 6 months in 60% of the patients; in the rest, in whom the lesion was more extensive, it lasted longer.

PUBLIC HEALTH

Effect of Ingestion of Distilled Spirits on Automobile Driving Skill. B. B. Coldwell, D. W. Penner, H. W. Smith and others. Quart. J. Stud. Alcohol 19:590-616 (Dec.) 1958 [New Haven, Conn.]

The authors carried out practical road tests on 50 experienced automobile drivers who consumed known amounts of distilled spirits. Under the given experimental conditions, the impairment of driving skill was definitely evident in one subject in whom the venous blood alcohol level was 0.036%. Signs of impairment were observed in 5 out of 7 subjects whose venous blood alcohol levels at the time of driving did not exceed 0.05%. Heavy drinkers showed less impairment of driving performance than light drinkers with the same blood alcohol levels, but signs of impaired driving ability were exhibited by 8 out of 10 heavy drinkers with venous blood alcohol levels ranging from 0.051 to 0.12%. Not one subject in whom the blood alcohol level was around 0.15% was able to maintain his driving ability as shown before drinking. Twenty-five drivers manifested significant impairment of their driving abilities when their venous blood alcohol level was 0.078%. The impaired ability in handling cars, such as manipulation of clutch, brake, gearshift, and accelerator, even at a relatively low venous blood alcohol level, was the most striking feature in the tests, in contrast to the drivers' skill to avoid stanchions. The experimental driving situation favored the subjects; therefore, one may assume that the influence of alcohol would be more pronounced on the driving performance in urban areas than on that observed in the tests.

Vaccination Against Poliomyelitis with Living Avirulent Viruses: Preliminary Report. F. Buser and M. Schär. Schweiz, med. Wchnschr. 88:1282-1284 (Dec. 20) 1958 (In German) [Basel, Switzerland].

Killed or living viruses of attenuated virulence are required for active immunization against poliomyelitis. Salk vaccine belongs to the first group; it contains strains of 3 types of poliomyelitis virus inactivated with formaldehyde. Since the Salk vaccine has been used in about 100 million persons and has given protection against the paralytic form of poliomyelitis, it may seem superfluous that immunization experiments are still being carried out with avirulent poliomyelitis viruses. However, test immunizations with living viruses date back to 1950, whereas "field trials" with the Salk vaccine were not begun until 1954. Both types of immunization have their advantages and disadvantages. Simultaneous immunization against all 3 types of poliomyelitis and absence of excretion of virus are some of the advantages of the killed virus vaccine of the Salk type. Oral administration, good and prolonged immunity, and absence of allergic reactions are advantages of immunization with the living avirulent virus.

The authors felt that the advantages of immuniza- with living viruses justified further vaccination experiments under clinical, virologic, and serologic control. They administered the attenuated type 1 poliomyelitis virus of H. Koprowski, known as the "Chat-Strain," by mouth to 115 persons (40 adults, 46 children, and 29 infants). The immunization produced no symptoms in any of these persons, and no case of poliomyelitis was observed during the immunization and for 3 months thereafter in the locality where the test persons resided. Poliomyelitis virus was demonstrated in the stools on the 10th day in 90% of the vaccinated infants and children and in 45% of the adults. Fifty-eight of 60 persons who had no antibodies against poliomyelitis virus, type 1, before the oral immunization showed a titer increase to 1:50 and higher. Only 2 adults showed no measurable increase in antibodies.

BOOK REVIEWS

Treatment of Cancer and Allied Diseases. Volume I: Principles of Treatment. By fifty-five authors. Edited by George T. Pack, M.D., F.A.C.S., Attending Surgeon, Memorial Center for Cancer and Allied Diseases, New York, and Irving M. Ariel, M.D., F.A.C.S., Associate Clinical Professor of Surgery and Associate Attending Surgeon, New York Medical College, Flower and Fifth Avenue Hospitals, New York. [To be in nine volumes.] Second edition. Cloth. $22.50. Pp. 646, with 505 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1958.

This is the first of nine volumes to be published. The other eight are to be concerned with specific neoplasms according to their origin in anatomic areas or systems. The first edition was in two volumes of such size as to be read only at a sturdy desk or table; the present volume is considerably smaller than the earlier books but still too heavy for armchair use or for reading in bed. Fifty-five authors have contributed to this volume alone, to accomplish a general review of organization (clinics and home care), diagnosis and pathology, some features of surgical therapy, methods of irradiation (5 of 10 section are devoted to this), hormonal treatment, chemotherapy, care of incurables, and reporting of end-results.

It is obvious that in the 37 chapters there is much important information although the overlapping, the conflicts of opinion, and the rapid obsolescence common to all such encyclopedic efforts are apparent here. Subjects which are presented in a superior fashion in the opinion of this reviewer include biopsy diagnosis, exfoliative cytology, electrosurgical treatment, radiosensitivity, the physical basis of radiation therapy, chemotherapy, and the reporting of end-results. The last-named section provides clear, practical guidance on the "why" and "how" of pertinent statistical methods. In a chapter on care of the patient before and after operation Ariel and Pack present a scholarly review of the problems in the biochemical and metabolic changes that follow the operative treatment of cancer. There is room for doubt that the practicing surgeon's basic knowledge will be enlarged significantly thereby, but the neophyte should be acquiring such information as part of his formal training.

Although there are advantages in low-voltage, short-distance (*sic*) x-ray treatment of surface lesions, the measurement of tumor dose by the "D½" or any other method is tricky, and much of the information presented in this connection is unconvincing. An important section on current palliative treatment by hormonal methods unhappily is poorly organized, frequently repetitious, and sometimes inaccurate. Written by one of the pioneers in the androgenic therapy of mammary carcinoma, this section shows a strong bias for androgens and perpetuates some of the myths which persist regarding this type of treatment. These errors include a belief that androgens given for two months after oophorectomy will hasten the regression of disease, that androgens are superior in skeletal metastasis at any age, that 30% of all patients obtain regression with androgens, and that after regression does occur the hormone employed should be discontinued. Each of these statements is inconsistent with more recent reports of various authors, and in particular with the data reported periodically during the past decade—and this year in final conclusions on 580 androgen-treated and 364 estrogen-treated patients—by the Subcommittee on Breast and Genital Cancer, Committee on Research, American Medical Association. The latter report confirms the conclusions of various investigators, since rates of regression for metastasis in bone of 24% with androgens are equaled by 27% for estrogens, while in all other situations by age, site of lesions, and time of recurrence, estrogens are either equal or superior to androgens in women four or more years postmenopausal. Other inaccuracies in this chapter are an apparent confusion of 'fibroadenoma' with dysplastic adenosis, an expression of the invalid taboo against substitutional use of estrogens for genuinely severe menopausal symptoms in women previously treated for breast cancer, a failure to emphasize the dominant role of orchiectomy in prostatic carcinoma, and a tacit approval of adrenalectomy for the latter neoplasm. Perhaps a clue to the unsatisfactory state of this section is found in the 141 references listed; divided by five-year intervals beginning in 1946, 52 of the bibliographic items were published prior to 1946, 41 and 43 in the next two five-year periods, and only 5 in 1956 or later. A single area so deficient must dampen one's admiration for the whole. The penalty for the lapse of time from manuscript to book is particularly evident in connection with methotrexate, triethylene melamine, triethylene thiophosphoramide (Thio-Tepa), nitrogen mustard, Methadone hydrochloride, and pantopon hydrochloride.

This is still a valuable reference source for libraries. The physical features of the book are beyond criticism. The index is detailed, and there are for all chapters reference lists of some length, inconveniently massed at the back of the book. Noted on page 609 is the most entertaining title since megavoltage units first made headlines (chapter 18, 12). It concerns the application of "Sugar-Hard X-Rays," but seems to give too little credit to the source, which is the first 1-Mev unit developed by Mudd at the California Institute of Technology.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUESTIONS AND ANSWERS

HISTAMINIC CEPHALALGIA

To the Editor:—*A 56-year-old man who has had histaminic cephalalgia for 10 years has shown only fair response to a course of histaminic desensitization with an ergotamine and caffeine preparation, aspirin, ACTH, and orally given steroids. What other treatment should be tried?*

Alexander Wallace III, M.D., Los Angeles.

Answer.—In a recent article, entitled "Histamine Cephalalgia and Its Relation to Migraine" (*Ann. Allergy* 16:300, 1958), Unger concluded that histaminic cephalalgia is characterized by attacks of excruciating unilateral facial pain, inflammation of the eye, and rhinorrhea or blocking of the nose on that side; one of his patients was relieved by abstinence from pork, another by abstinence from milk, and a third by removal of infected teeth; migraine headache was also present in two of these three patients; histaminic cephalalgia and migraine headache are probably closely related; although histamine injections usually give good results, this does not prove that elaboration of histamine at the site of the pain causes the symptoms; and the theory that injections of histamine lead to desensitization is likewise not proved. A thorough search should be made for a focus of infection, especially dead or abscessed teeth or infected tonsils, and elimination diets, beginning with one from which milk, pork, and chocolate are rigidly excluded, should be followed for about two weeks. Then, if there is no relief, new diets should be tried, e. g., one which excludes wheat and other cereals and then one with avoidance of meat, fish, fruits, and vegetables, in succession.

GENERAL ANESTHETIC FOR A CHILD

To the Editor:—*Is there any type of general anesthetic which a pediatrician may use without risk to the patient in the performance of such minor operations as sutures of skin wounds, abscess drainage, and reduction of fractures or luxations?*

Juan Silverio, M.D., Marianao, Cuba.

Answer.—There is no type of general anesthetic that may be used without risk to the patient, no matter how minor the operative procedure is. The risk of anesthesia involved in outpatient procedures is greater than most, because patients are excited and often have quantities of undigested food in their stomachs. These two factors add such danger to the average risk of anesthesia that experienced anesthetists regard such cases as especially hazardous. Unless carefully managed, such patients struggle and resist anesthetic induction and later may aspirate vomitus and die. Such tragic accidents occur with alarming frequency throughout the United States. How then, does one treat children who require minor emergency operations? When possible, it is wise to allow an experienced anesthetist to assume the responsibility. Often a pediatrician or practitioner must act for himself, however. In such cases, he should definitely avoid the hazards involved in attempting both to anesthetize his patient and to perform the operation. There are several alternatives. At the outset, one should take time to quiet the child with a mild sedative which will calm but not depress him. Pentobarbital, or a relatively small dose (0.5 mg. per year of age) of morphine, is effective. Time must be allowed for such a drug to act. An understanding physician can accomplish a great deal by reassuring the child and gaining his confidence.

If, after this preparation, the physician uses local infiltration anesthesia, he will be able to take care of most minor lacerations and similar injuries. Ethyl chloride spray may be used if abscesses are to be opened. If a Colles' fracture is to be reduced, the fracture site may be infiltrated with a 1% solution of procaine or the fracture may be adroitly reduced without anesthesia. These measures fall short of the ideal, but they are definitely safer than would be the use of a general anesthetic by an untrained person. In many areas, a pediatrician may obtain enough training in anesthesia to justify his use of short-acting agents, such as vinyl ether, which has definite advantages for minor operations. This agent, however, may cause severe convulsions and hypoxia, or toxic liver necrosis, and consequently should not be used by trial and error methods.

ADRENOCORTICAL STEROIDS

To the Editor:—*Is there any indication for or any adequate proof of the advantage of adrenocortical extract over the various synthetic adrenal steroids (prednisone or ACTH) in the treatment of any condition? Please comment on the use of adrenocortical extract in chronic congestive heart failure, presumably refractory to routine therapy; it has been said that, in this condition, adrenocortical extract has advantages over ACTH.*

Warren F. Wilhelm, M.D., Kansas City, Mo.

Answer.—Adrenocortical extract is theoretically a composite of the steroids found in the adrenal cortex and so should have multiple effects. For practical purposes, however, it resembles desoxy-

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

corticosterone acetate in its action; that is, it is more like the mineralocorticoids than the glucocorticoids. Such synthetic adrenal steroids as prednisone and ACTH have primarily a glucocorticoid effect. Therefore, adrenocortical extract would be preferable in those situations requiring a mineralocorticoid effect, for example, in acute adrenal insufficiency, where a low serum sodium level and a low extracellular fluid volume are the immediate concerns. In regard to chronic congestive heart failure refractory to routine therapy, one must first decide whether steroids of any kind are indicated. This class of drugs has until recently been considered contraindicated in congestive heart failure because of salt and fluid retention, which may be a serious matter. In recent years, however, some apparently paradoxical effects of steroids in inducing diuresis have been observed in patients with intractable congestive heart failure. The exact mechanism of this diuresis remains to be elucidated. Various data suggest that renal tubular reabsorptive mechanisms may be involved, antidiuretic hormone activity may be inhibited, and/or aldosterone may be influenced. As long as the exact physiological explanation for the ability of steroids to cause an increase in urinary output under certain circumstances remains undetermined, it is difficult to state whether ACTH or adrenocortical extract would theoretically be more effective. Although both have been used, in most of the reported studies ACTH, cortisone, or other agents primarily glucocorticoid have been administered preponderantly. For this reason and because adrenocortical extract is extremely expensive and relatively less available, ACTH would seem preferable should one believe that the steroids are worthy of trial in severe congestive heart failure.

EXTREME LONGEVITY

To THE EDITOR:—*A man in a nearby place claims to be 185 years old. There are no records to substantiate his statement. Is any method available to gain at least an approximate estimate of his age? Is the technique of using carbon-14 or any other test applicable in this regard, for example, a test on dental enamel? All other tissues of the body are renewed too often to supply desired information.*

Manouchehr Gueramy, M.D., Shiraz, Iran.

ANSWER.—No chemical or anatomic methods are available to determine an adult's age. The use of carbon-14 is not practicable, because the turnover of carbon in the body is too rapid. In other words, the test is of little value in determining the age of living substances. In addition, the accuracy of the carbon-14 test on inert objects varies up to 150 years one way or the other.

PINWORMS

To THE EDITOR:—*A patient has had a persistent pinworm infestation. She was exposed to them by her child seven years ago. Since then, she has had many courses of treatment. Although all the accepted drugs have been used and her home technique made sure of, she still has a recurrence every 6 or 7 months after apparently being cured. The standard treatment, including mercurial ointment, enemas, a drug by mouth (piperazine tartrate, gentian violet, oxytetracycline, and other agents), and appropriate care of the hands and linen, has been used many times. She is an intelligent, extremely neat person. The children have been rechecked regularly and no worms have been noted since the first attack seven years ago. What can be done for this patient?*

M.D., New York.

ANSWER.—Since the children in the family have not had pinworms since their first attack and since the mother is described as an extremely neat person, the diagnosis of enterobiasis is questionable. Is she a compulsive, highly literate woman who may be upset by the problem and who keeps imagining infection? Mothers have been seen who become severely upset about pinworm infestation and describe "worms" that do not exist. The diagnosis should be checked carefully by Scotch-tape smears taken before bathing. A series of smears should be made on three consecutive mornings, and if these show negative findings she should be firmly assured that no worms are present and told to stop looking for them. There are no carriers of pinworms. This common intestinal parasite of children does not infect household pets, as is commonly suspected.

ANSWER.—It is probable that the continued source of reinfection is in the home and that one or more other members of the family harbor asymptomatic infections. The simplest and most logical procedure to follow in this case would be to simultaneously treat all members of the family with piperazine, using a dosage of 50 mg. per kilogram of body weight per day, but not exceeding 3 Gm. per day, for eight consecutive days. The best results have followed the administration of the total daily dose, at one time, about two hours before breakfast.

ANSWER.—The ubiquitous pinworm, Enterobius vermicularis, evades all sanitary barriers and invades all classes of society. It is the most common parasitic worm of civilized man. Its peculiar, brief life cycle, lasting two to six weeks (seldom three months or longer), makes infection and reinfection sure and prompt. Eggs, when ingested, hatch in the small intestine and worms occur in various stages of development from the ileum, cecum, and appendix through the colon and rectum. There is no deposition of eggs in the lumen of the host's intestine. The gravid females, when ready to oviposit, swarm into the rectum, usually at night. They wriggle out of the anus, causing pruritus or rectal pain. The consequent rubbing and scratching of the affected parts results in crushing the worms and smearing many thousands of embryonated eggs into the perianal area. Eggs soon mature on exposure to air and become infective. Thus, fingers, underwear, night clothes, and bed sheets create a risk of continuous or interrupted reinfection with eggs which is greater for the infested person than for others. Finger transmission of eggs from anus to mouth is the principal mode of massive or cumulative infection. Some larvae, emerging in the moist surroundings of the anus, may enter the intestine by the anal route. Eggs dislodged from the host's perianal region become widely disseminated in the house. Airborne infection with dried eggs from room dust via the mouth and nose results in chronic light infections. These singular modes of infection might help to explain the peculiarities of the case presented.

Although perianal itching at the time of the emergence of gravid females from the anus is a frequent occurrence, many adults and children harboring pinworms experience little or no pruritus and, therefore, are not conscious of infection. Pinworm infection has been discovered by the Scotch-tape anal swab technique in many unsuspecting parents of already infected children. Such persons may be justifiably regarded as the carriers of infection. There are, on the other hand, others who suffer severe pruritus from even light infections with pinworms. They probably have become allergic to the worms or their products.

The following procedures are recommended for prophylaxis and treatment: 1. All members of the household should be examined or reexamined, including the husband and servants, by the Scotch-tape swab technique. The swabs should be done early in the morning, before a bath; a series of seven should be taken on alternate mornings and especially any morning after a night when itching has occurred. All those found to be infected should be treated simultaneously. 2. The patients should be cautioned to wash hands before eating and smoking. 3. They should be told to change bed sheets, underwear, nightgowns, and similar items daily. The bed sheets should not be shaken but removed gently and laundered after each use. The rugs, curtains, sofas, chairs, and table-tops should be vacuum-cleaned once a week. 4. Before retiring at night, the patient should place a liberal amount of 5% ammoniated mercury ointment on a piece of polyethylene plastic sheet and apply it to the perianal area, holding it in place with a sanitary napkin. The patient should remove and discard it the next morning in the bathroom and take a shower, thoroughly washing the perianal area with soap and water. Freshly laundered underwear should then be put on. 5. The bathtub, toilet seat, the bathroom floor, and fixtures should be wiped with 2% saponated cresol solution.

Two new and usually effective therapeutic agents are now available: Dithiazanine, a cyanine dye, is supplied in the form of 0.1 Gm. tablets, and the adult dosage is 200 mg. (two tablets) three times daily for five consecutive days (Schwartzwelder and others, *J. A. M. A.* 165:2063-2067 [Dec. 21] 1957). Pyrvinium chloride, also a cyanine dye, marketed as a strawberry-flavored suspension, is given in a dosage of 2 mg. per kilogram of body weight per day, in two equal doses daily for six consecutive days (*Am. J. Trop. Med. & Hyg.* 7:212, 1958).

RECURRENT PHLEBITIS

To the Editor:—*Over the past five years, a married woman has suffered at intervals of months or years from attacks of phlebitis involving her legs from ankle to groin (three times on the right and twice on the left). Once she suffered a pulmonary embolus. On two occasions she was in Seattle, Wash., once in Long Beach, Calif., and twice here in Mexico, and everywhere physicians have been at a loss as to the cause. Treatment has included rest, hot packs, antibiotics, and anticoagulants. Attacks have lasted one to eight weeks. Please suggest a course of treatment.*

Richard H. Lyon, M.D., Jalisco, Mexico.

Answer.—This patient seems to be suffering from recurring infectious thrombophlebitis with lymphedema. The original cause is not known, but such patients are likely to develop recurring episodes with chills and fever, precipitated by mild trauma or any systemic infection, however mild. This is particularly true with recurring upper respiratory infections. In addition to rest in bed, continuous warm wet compresses over the limb, elevation of the foot of the bed, antibiotics, and anticoagulants, methacholine chloride, administered by iontophoresis every other day for a series of 10 treatments, and use of an oscillating bed are often helpful. These measures should improve the venous circulation and help overcome spasm of both the veins and arteries. Vasodilators are usually prescribed, such as nylidrin (6 mg. given three times a day before meals) and papaverine hydrochloride (60 mg. given after meals and at bedtime). In chronic cases, when there is evidence of an active perivenous inflammation, trypsin therapy (2.5 mg. given twice daily for 10 days) is helpful. The condition usually is reasonably controlled in two or three weeks. The important thing is to continue the treatment for a prolonged or indefinite period. The patient should wear an elastic support for at least three months. Anticoagulant therapy should be continued for at least six months but should be properly supervised with prothrombin time estimations. Another suggestion which may be applicable here would be to continue the antibiotic therapy, particularly if the source of infection is determined. Sometimes it may be in the sinuses, throat, or urinary tract. In such cases 200,000 units of penicillin and 500 mg. of a triple sulfonamide, such as sulfadiazine, sulfamerazine, and sulfamethazine, may be given daily for a prolonged period. This measure may be helpful in preventing recurrences.

PAIN IN LOWER EXTREMITY

To the Editor:—*A man, aged 47, who works actively every day complains of pain in the left lower extremity. It began suddenly seven years ago while he was walking down a steep hill. The pain in his left hip, thigh, and calf at that time was so severe he could not bear weight on the left side. He spent the next hour or so working himself up to the point of being able to walk again after sliding down the hill the rest of the way and walking to the car. Then he recovered completely, but ever since then, whenever he walks 100 yards quickly, a sudden pain in the thigh and calf stops him "dead" and he has to take the weight off the left lower extremity and rotate it inward and outward at the hip, which relieves it within five minutes. Then he is perfectly all right, with no residuals. He has tried sitting down when the pain strikes him, but that does not help. If he is walking more slowly the pain comes gradually but is treated the same way, and if he walks slowly enough he can walk all day without pain. At worst the calf will cramp; otherwise, there is a deep-seated pain in the whole thigh and leg which he cannot localize because there is no tenderness. A few times the foot has tingled slightly. There is no subjective skin temperature or skin color change. Pulsations in the dorsalis pedis artery are good. There is never any swelling or trophic change. Five or six physicians, including a specialist, have examined him. Please suggest treatment.*

Robert S. Hamilton, M.D., Conrad, Mont.

Answer.—From the history, it is presumed that the circulatory function studies have given normal results. It is possible that this patient may have arteriospasm with a claudication-like pain at times. He may have some marked irritation of the posterior nerve roots. This may have been a sacroiliac condition at the onset or, more likely, a disk syndrome. Walking down the hill may have set off some pathological changes of the ligaments around the spine, which permitted some injury to the spine or slipping of an intervertebral disk. It is also possible that the disk may slip in and out at times and may produce marked symptoms alternating with times when patient is symptom-free. This patient should be thoroughly x-rayed in reference to some spinal injury with either a neurosurgeon or an orthopedist supervising the studies. A myelogram may throw some light on this case and would enable any pathological findings to be corrected. In the meantime, the patient should be treated with analgesics and vasodilators to overcome the arteriospasm. Further investigation should be carried out to arrive at the source and attempts made to correct the offending factor.

CHLOROTHIAZIDE AND OLIGOHYDRAMNIOS

To the Editor:—*An 18-year-old primigravida was recently delivered at term of a girl weighing 6 lb. 2 oz. (2,800 Gm.) and showing bilateral marked talipes varus but no obvious bony abnormalities. Oligohydramnios seemed to be present. During the last six weeks of pregnancy the patient was almost continuously on therapy with chlorothiazide because of excessive weight gain (25 lb. [11.3 kg.] in four weeks) and pitting edema, with a rise in blood pressure from 120/70 to 160/90 mm. Hg in the same four weeks. No albuminuria was found. With use of this drug, the patient lost 14 lb. (6.4 kg.). What is the influence of chlorothiazide on amniotic fluid, since the oligohydramnios appears to be a causal factor in the development of the clubfeet?*

M.D., Virginia.

Answer.—A number of drugs having carbonic anhydrase inhibitory activity have been used in an effort to effect a reversal of the sodium and water retention characteristic of the late toxemias of pregnancy. Of these drugs, chlorothiazide seems to be one of the most effective. The effectiveness of this type of therapy will be apparent clinically by a rapid weight loss, a diminution in edema, and occasionally a reduction in the tone and size of the uterus. The latter is especially apparent when polyhydramnios has been present. Frequent circumferential measurements will provide the best evidence of a diminishing volume of amniotic fluid. The relationship between oligohydramnios and the presence of skeletal or muscular abnormalities in the fetus, such as talipes varus, is obscure. Skeletal and muscular defects occur frequently in an abdominal pregnancy where there may be no amniotic fluid protection. On the other hand, many similar defects have been observed in premature infants and aborted fetuses when no constriction or abnormal pressure factors seemed to be present. It would seem most unlikely that the bilateral talipes varus present in the infant described was the result of the use of chlorothiazide. Although this possibility cannot be absolutely excluded, it should be borne in mind that the hazards incident to the inadequate treatment of preeclampsia may be exceedingly great. Certainly, the active treatment of preeclampsia should be the primary objective.

COAGULATION TEST

To the Editor:—*Years ago a blood clotting test, known as the coagulation valence, was described by Fonio. The basis of the test is the ability of blood to clot when mixed with a substance which inhibits coagulation, in this case magnesium sulfate. What is the anticoagulant mechanism of magnesium sulfate, which is evident even with low dilutions of this salt? What clotting factor or factors in the blood is removed by it?* *J. H. Rogers, M.D., Gadsden, Ala.*

Answer.—Magnesium sulfate, as well as other salts of magnesium, depresses coagulation. High concentrations of calcium salts and even sodium chloride also effect an inhibitory action of coagulation. It is likely that this is a nonspecific effect and probably is not specific for magnesium. This consultant is unaware of any recent work that has been done to determine in what phase of the clotting mechanism these inorganic salts act. The older literature is noninformative, because the various clotting factors were not differentiated until recently.

Answer.—Although much work has been done on the relationship of certain cations, particularly calcium and other alkaline earth elements, to the coagulation mechanism, there is still much ignorance regarding the precise clotting factors on which they act. Interest in this area has recently been reawakened in the light of our newer knowledge of the coagulation sequence. The following information regarding the mechanism by which magnesium sulfate may act as an anticoagulant is largely derived from early work of Stefanini and Quick (*Am. J. Physiol.* 152:389, 1948), who made studies on blood decalcified by an ion exchange resin (Amberlite). It was demonstrated that calcium is both a procoagulant as well as an anticoagulant, depending on the concentration used when re-added to the decalcified plasma. This has been recently reconfirmed with highly purified materials, demonstrating the quantitative relationships required for the biological activation of highly purified prothrombin (Goldstein, Izak, and Zonderman, *Fed. Proc.* 16:48, 1957; Alexander, in Transactions of the Fourth International Congress of Biochemistry, New York, Pergamon Press, 1958, to be published).

DYSPNEA AND ABDOMINAL DISTENTION

To the Editor:—*A 76-year-old woman performed such heavy work as pitching hay until two years ago. Her only complaint was dyspnea easily relieved by stopping work for a few minutes. About 10 years ago a 25-lb. growth (probably an ovarian cyst) was removed from her abdomen through a midline incision. She has had a "big stomach" ever since. All other findings are normal, except for a marked meteorism; her abdominal walls are felt to be under great pressure. This condition has been present since her operation. Palpation is unsatisfactory, but there is no indication of mass or free fluid. Although she has dyspnea, she can touch the floor easily when bending over with her knees straight. What might cause such a condition? Would it be safe to give a trial dose of neostigmine?* *M.D., New York.*

Answer.—The meteorism which was noted by the examining physician might well contribute to this patient's dyspnea, but one would have to attribute it mostly to the arteriosclerotic heart disease which must be present. The enlargement of the abdomen may be due to many causes, but the three most obvious, in view of the patient's history, are recurrent tumor, ascites, or intestinal distention. In view of the time since her operation and the absence of masses or free fluid, the sole cause must be a distended colon. The colon is probably dilated, secondary to a functional or organic partial obstruction in the lower sigmoid or rectosigmoid. A functional obstruction may be due to degeneration of the myenteric plexus caused by nutritional deficiency. Partial organic obstruction could be produced by diverticulitis, operative adhesions, or a chronic twisting or kinking as the sigmoid enters the pelvis. The diagnosis will depend on sigmoidoscopy, roentgenograms of the abdomen, and a barium enema. If these studies demonstrate a functional obstruction (acquired megacolon) it may be controlled by enemas and saline solution laxatives. The various choline derivatives have not proved satisfactory in such older patients because of their cardiovascular side-effects.

CARBON MONOXIDE AND CORONARY INFARCTION

To the Editor:—*Could a few whiffs of fumes from an automobile exhaust precipitate a coronary infarction? A 65-year-old man inhaled such fumes and within 15 minutes developed an acute coronary occlusion.* *M.D., Illinois.*

Answer.—The question implies a very brief exposure to automobile exhaust gas, and it can be assumed that this exposure was not followed by any long period of unconsciousness due to deprivation of oxygen. It is highly improbable that there could be any connection between the exposure described and the appearance of the coronary accident. Automobile exhaust gas does have other components than carbon monoxide, usually small amounts of hydrocarbons, but the effect of these contaminants on the general toxicity of the exhaust gas is negligible. Exposure to carbon monoxide results in the reduction of the available oxygen in the respired air. Symptoms are primarily due to oxygen deprivation, depending on the concentration of the carbon monoxide in the air and the duration of the exposure. The effect may be entirely negligible or, when severe, will manifest itself chiefly by injury to the nervous system, which characteristically shows the effect of oxygen deprivation to the tissues. Any effect on the circulatory system would be secondary and the result of a serious exposure to carbon monoxide, which would have resulted in a prolonged period of unconsciousness. Many observers, reporting in the past, attributed various changes noted in the blood vessels and heart to carbon monoxide exposures, but little evidence has ever been presented to justify these claims. The exposures assumed to have produced vascular effects were extreme. The vascular changes attributed to carbon monoxide exposure could not have occurred in the brief time mentioned, in which the appearance of a coronary occlusion was within a few minutes after exposure to the exhaust fumes.

POSTOPERATIVE PULMONARY EMBOLISM

To the Editor:—*Does general anesthesia contribute to fatal postoperative pulmonary embolism? This tragic complication continues to occur in spite of good operative and postoperative care, including such measures as maintenance of blood pressure during operation, elevation and massage of the lower limbs, elimination of pressure on the lower extremities, and early ambulation. Is the incidence of fatal postoperative pulmonary embolism greater after general anesthesia than after spinal anesthesia?*

F. A. Procunier, M.D.
Waterford, Ontario, Canada.

Answer.—This consultant does not believe that general anesthesia contributes in any way to nonfatal or fatal postoperative pulmonary embolism. With few exceptions, pulmonary embolism is a result of a bland thrombus in the vein, one which is not associated with phlebitis, and, therefore, the clot is not firmly attached and can become detached. This has been called phlebothrombosis in contradistinction to thrombophlebitis. Phlebothrombosis is probably due to two predisposing factors. One is an increased tendency of the blood to clot, resulting from tissue injury. It apparently does not make much difference whether the cause of the tissue injury is operative trauma, accidental trauma, or invasion of tissue by neoplastic disease or infection. Whenever there is tissue injury, there is an increased tendency of the blood to clot. The other predisposing factor is circulatory retardation, and it is for this reason that most phlebothromboses occur in the lower extremity, because of lack of movement of these extremities in a patient who is in bed. The incidence of pulmonary embolism apparently is no higher in patients operated on under general anesthesia than in those operated on under spinal anesthesia.

DIVERTICULITIS

To the Editor:—*An 82-year-old woman who had been in good health suddenly developed intestinal obstruction due to an inflammatory diverticulum in the sigmoid colon. A cecostomy was performed to relieve obstructive symptoms. The patient's condition returned to normal except for a profuse watery fecal discharge through the fistula, requiring four heavy dressings daily. At the time of writing, three months after onset, there has been no normal bowel movement. Should a colostomy be performed and the fistula closed?*

C. C. Dillon, M.D., Sidell, Ill.

Answer.—Since the patient's condition has returned essentially to normal, surgical exploration in the hope of resecting the segment of diverticulitis would be in order. If this cannot be done, a colostomy might be established in the descending colon and proximal to the diverticulitis. In due time, and possibly several months after resection or after colostomy, the cecostomy could be closed. This should make the patient much more comfortable.

PROTEINURIA

To the Editor:—*What is the significance of a finding of 2+ or more albumin in the urine with or without 5 to 10 red blood cells or 5 to 10 leukocytes? In review of hospital records, this has been a common finding in patients who are hospitalized for conditions other than genitourinary disease. Does this show a lowering of kidney reserve, or is it just a manifestation of a generalized toxic condition? A woman who is menstruating has 4+ albumin in the urine with gross blood. Can this finding be attributed entirely to menstruation? A patient who comes in for an operation, such as a herniorrhaphy or dental extraction, may show 2+ albumin with 10 red blood cells and 10 leukocytes in the urine. Is this significant of genitourinary pathology? A point of discussion is that these findings are to be ignored if they are not based on catheterized specimens.*

Nerico W. Pioppi, M.D., Southbridge, Mass.

Answer.—The finding of 2+ albumin in the urine in the presence of a generalized toxic condition is of no particular significance, but, in an otherwise healthy patient with only a few white or red blood cells in the urine, such a finding should be carefully investigated. In the menstruating woman, the finding of a high degree of albuminuria can be entirely normal. The best way to determine this is to wait until the menstrual period is over and recheck one or two more specimens. It is true that, with the highly sensitive tests so commonly used today, the presence of a trace or up to 1+ albuminuria may be within normal limits. This consultant does not believe that it is always necessary to have a catheterized specimen of urine to appreciate the importance of albuminuria, but it is impossible to make any suggestions concerning cellular findings in the urine specimen from a woman unless it is a catheterized specimen.

GASES IN NEON LIGHTS

To the Editor:—*What gases are used in neon lights? Are they injurious to persons working with them?*

W. J. Tucker, M.D., Ashland, Wis.

Answer.—The gases likely to appear in the neon type of light, but not all in any one style or form, are neon, krypton, argon, xenon, and helium. All of these gases are essentially harmless, acting only as simple asphyxiants. Any damage connected with the manufacture of these light tubes is more likely to be identifiable with the phosphors contained rather than the gases. Although all beryllium is believed to have disappeared from ordinary fluorescent lighting tubes, it may be suspected that some beryllium may be surreptitiously introduced into some of the neon type of tubes. If this is true, this practice is more likely to exist in small rather than large manufacturing plants.

RESTORATION OF DIVIDED VAS DEFERENS

To the Editor:—*A 30-year-old man stated that at the age of 27 he had a partial vasectomy, which apparently failed in that the sperm count remained high. One testis had previously been removed, apparently because of a severe injury. The second time the vasectomy was performed, an inguinal incision was made and, presumably, a segment of the vas deferens was removed. The patient said his physician told him the vas was removed "down next to the prostate." The patient has two children by a former marriage, and now he is anxious that his present wife become pregnant. The problem seems to resolve itself into two approaches: (1) reanastomosis of the divided vas deferens and (2) aspiration of spermatozoa from the epididymis. Please offer suggestions as to the details of aspirating spermatozoa for cervical injection and give references for surgical restoration of the divided vas deferens.* *M.D., Illinois.*

Answer.—Reanastomosis of the divided vas deferens has proved successful to a varying degree. In recent years several reports (O'Conor, *J. A. M. A.* 136:162-163 [Jan. 17] 1948; Dorsey, *J. Internat. Coll. Surgeons* 27:453, 1957) have been made of a series of such operations which have proved to be successful in many cases. If reanastomosis is attempted, it should be done by a urologist who has had wide experience with this operation. Aspiration of spermatozoa from the epididymis has not been successful in many cases. In the first place, it is difficult to collect a sufficient number of spermatozoa by aspiration to achieve insemination. Furthermore, the spermatozoa would not have opportunity to mature without having passed through the epididymis and vas. The possibility of collecting a sufficient number of spermatozoa by means of an operation causing dilatation of the vas has been suggested.

DISINFECTION OF FLOORS

To the Editor:—*What germicide is best suited for cleaning floors that might be contaminated with Mycobacterium tuberculosis? Is any antiseptic more effective than phenol?*

Denvil F. Crowe, M.D., Paris, Tenn.

Answer.—Washing the floors and woodwork of rooms contaminated by tubercle bacilli with soap and hot water and subsequent wetting with a 2 to 5% solution of *o*-phenyl and methyl phenols remains the standard recommendation. Among the newer compounds, a 2.5% solution of *o*-phenyl and *p*-*tert*-amyl phenols with potassium ricinoleate is highly recommended; it has the advantage of being odorless.

REPEATED CONGENITAL DEFECTS

To the Editor:—*One year ago, a 22-year-old woman delivered a female infant who died shortly after birth due to bilateral cystic kidneys, hydrocephalus, porencephalic cyst, intra-atrial septal defect, and tricuspid valve atresia. Recently, she delivered a second female infant who died shortly after birth due to bilateral cystic kidneys, hydrocephalus, and encephalocele. She has had no other pregnancies. Neither the husband nor the wife has any congenital defects, and there is no history of such defects in their families. What advice should be given to this couple regarding a future pregnancy? Should husband and wife be investigated for congenital kidney defects? Would semen examination be of any value?*

Edward B. O'Connell, M.D., New Haven, Conn.

Answer.—The abnormalities of these infants could be due to a combination of hereditary defects and "errors of development." It is impossible to determine which is the more important in each individual abnormality. Hydrocephalus is often inherited as a recessive characteristic. If it is inherited in this instance, both parents had the tendency, which was not, however, expressed in them. The statistical expectation would be that one child out of every four would be hydrocephalic. Since the mother has already borne two affected children, there would be a good chance that the next one would be free from this defect, but the other serious defects might be present. In view of the number and seriousness of these, the prognosis is so doubtful that the couple might well be advised not to risk another pregnancy. Semen examination would be of no value.

HYPOGLYCEMIA

To the Editor:—*Is there any truth to the theory that a low blood sugar level (cause unknown) may be made worse by the administration of dextrose or the frequent use of glucose (hard candy) given orally? The supposed theory is that the dextrose will activate the pancreas to produce more insulin and thus further reduce the blood sugar level. A patient had a blood sugar level of 52 mg. % and weak spells. Exploration was done, and no tumor could be found in his pancreas. He now says he gets along better if he uses no sugar and thinks his blood sugar level is up to 105 mg. %. Is this likely?*

George C. Christie, M.D., Canon City, Colo.

Answer.—As far as an immediate effect is concerned, the administration of dextrose tends to elevate the blood sugar level, but as a long-term effect in persons with so-called functional neurogenic hypoglycemia a high carbohydrate intake usually aggravates the condition. This comes about presumably because of an overly great response of insulin-producing cells to the stimulus of a rising blood sugar level. In such persons the blood sugar level after an overnight fast is normal but may fall to hypoglycemic levels two or three hours after eating. Treatment consists of (1) a diet low in carbohydrate, liberal in protein, and with enough fat to provide adequate calories; (2) between-meal snacks which are low in carbohydrate; (3) small doses of phenobarbital and belladonna; and (4) relief from tension and stressful situations. Assuming that the patient in question does not have an islet cell tumor, these measures may prove beneficial. The article by Conn and Seltzer (*Am. J. Med.* 19:460, 1955) should be consulted.

POSTERIOR PITUITARY INJECTION AND GENERAL ANESTHESIA

To the Editor:—*Is the use of posterior pituitary injection as a local vasoconstrictor in surgery contraindicated when general anesthesia is used?*

M.D., New York.

Answer.—In anesthesia produced by agents having a direct action on the heart and, under some conditions, all commonly used general anesthetic agents are cardiac depressants, posterior pituitary injection should be avoided as a vasoconstrictor. This is due to the fact that this drug contains vasopressin tannate, which has a constricting action on the coronary arteries, and, when this is combined with myocardial depression, pronounced hypotension may result. Myocardial and coronary artery disease must also be considered as contraindications to the use of this drug. If this agent is slowly absorbed, there is little likelihood of a severe reaction, but as long as there is a possibility of accidental intravascular injection one must be prepared to accept the results of coronary constriction. If the patient is predisposed to asthma or if cyclopropane is being used, laryngospasm, bronchospasm, or bronchorrhea may also result from posterior pituitary injection.

Parsloe, C. P.; Morris, L. E.; and Orth, O. S.: Relationship of Various Anesthetic Agents to Action of Pituitrin, Pitressin, and Pitocin, Anesthesiology **11**:76-93 (Jan.) 1950.

TESTICULAR TUMORS

To the Editor:—*Is there any evidence that testicular tumors occur with any greater frequency in men who have had vasectomies?*

Joe J. Horn, M.D., Plainview, Texas.

Answer.—Vasectomy has no effect on the testis other than obstruction to the passage of its spermatozoa. Spermatogenesis and formation of Leydig's cells continue undisturbed. A review of the literature has disclosed no increased incidence of tumor formation of the testis after vasectomy. Occasionally, spermatozoa are found invading the tissue of the epididymis, producing a tumor-like swelling which is actually granulamatous. Such granulomas are not necessarily associated with vasal or epididymal obstruction.

COUGHING AFTER CATARACT OPERATION

To the Editor:—*A 60-year-old man has cataracts of both eyes. The vision of the right eye is 0 and of the left 20/250. The patient also has hypoparathyroidism, which is controlled, and more important, bronchiectasis of both lower lobes which causes frequent coughing. Is it possible to stop coughing during and for a few days after the cataract operation? Is it possible to keep the intraocular pressure steady after the cataract operation? The tension of the eyes is normal.*

Arnold Ernest Aszody, M.D., Corona, N.Y.

Answer.—With the present-day technique of cataract extraction and with the use of corneoscleral suturing of the incision, a patient who coughs during or after such an operation is no longer considered with the fear that was formerly held. An evaluation of the bronchiectasis should be made prior to cataract extraction. After this, the management of the pulmonary condition should be undertaken to clear up any infection. Both before and after operation, small doses of codeine or similar drugs may be used to suppress but not abolish the cough. The intraocular pressure can be maintained postoperatively by an adequate iridectomy at the time of operation, the use of miotics locally, and the oral use of any of the effective, long-acting inhibitors of cholinesterase, such as acetazolamide, chlorothiazide, and ethoxzolamide. None of these drugs should be used without the proper indication, namely, increased intraocular pressure.

GAMMA GLOBULIN DEFICIENCY

To the Editor:—*Two small boys have an extreme gamma globulin deficiency. The father's employment requires long periods outside the United States. Since these children probably cannot develop active immunization, is there any value in giving them anti-diphtheria-pertussis-tetanus (DPT) injections and would it not be dangerous to vaccinate them against smallpox? Would these children not have as much protection with their regular gamma globulin injections as if they were receiving active immunizations?*

Spencer C. Manrodt, M.D., Melbourne, Fla.

Answer.—It would be hazardous indeed to vaccinate these boys against smallpox. The risk of giving them DPT injections would far outweigh the possible good obtained. For maximum protection it would be safer and preferable to administer intramuscularly or subcutaneously (not intravenously) the proper dosage of pooled adult gamma globulin once every four to six weeks. The dose is computed by body weight. Infectious hepatitis, measles, poliomyelitis, and possibly other diseases should be prevented or ameliorated by 5 to 10 ml. of potent gamma globulin per 100 lb. of body weight. The antibody content of 1 ml. of gamma globulin should be the equivalent of 25 ml. of whole serum. Its use is accompanied by less discomfort and no reactions or hazards, if syringe and needle are properly sterilized and the site of injection properly cleansed with 70% alcohol and a sterile pledget of gauze or cotton. Gamma globulin deficiency can be managed by the administration of 0.1 ml. per kilogram of body weight monthly.

SMOKE POISONING

To the Editor:—*Are there lethal factors beyond carbon monoxide, heat, and asphyxia inherent in the smoke poisoning encountered in a burning building?*

I. G. Frohman, M.D., Rockaway Beach, N. Y.

Answer.—Depending on the combustible content of the building, the possibilities are legion. Among others are nitrogen dioxide leading to pulmonary edema, irritant aldehydes conducive to pneumonitis, and hydrogen cyanide from the partial combustion of such objects as wool rugs or wool upholstery. Sulfur dioxide is always present and might reach lethal concentration. Partial combustion may lead to the presence of hydrogen sulfide. Carbon dioxide may be active over and above its simple asphyxiant properties. Depending on the nature of the fire-fighting equipment, phosgene may arise from the decomposition of carbon tetrachloride. Particulate matter, such as carbon, contributing to the smoke may enhance the activity of some of the chemicals mentioned. This list could be expanded extensively. Many of the larger fire insurance companies publish lists of the major constituents of poisonous smokes.

TORTICOLLIS

To the Editor:—*Is there any satisfactory treatment for chronic wryneck? In a 48-year-old woman who is going through the menopause and whose general health is reasonably good, this condition has come on in the past few years. She now holds her head constantly on the left and at times she pushes it back to the normal position with her left hand. She was told to take meprobamate and found it of some aid. The general examination is negative except for moderate scoliosis in the cervicothoracic spine.*

Alan R. Anderson, M.D., Freeport, N. Y.

Answer.—Spasmodic torticollis is one of the movement disorders for which there is no satisfactory treatment. Tranquilizers, such as meprobamate, occasionally give slight relief, and some of the anti-Parkinsonian remedies may be of slight benefit; however, for the most part, drugs have little effect. Neurosurgical intervention is occasionally recommended but may provide no real improvement. This has consisted in removing a portion of the hypertrophied sternocleidomastoid muscle and section of various of the upper cervical roots. More recently, destructive lesions of the basal ganglions have been tried. These patients sometimes are helped by psychiatric counseling when there is evidence of marked emotional instability.

"TRI-OPTIC LENS"

To the Editor:—*An article in* Newsweek Magazine *(Oct. 27, 1958) stated that there is a tri-optic plastic lens that will give good vision. Is such a lens available on the market? Where can it be purchased?*

Odell J. Kirksey, M.D., Mulberry, Ark.

Answer.—Experience at several centers has shown that, generally, near-blind persons find more useful a particular lens for whatever their specific visual requirement may be than the complicated lens described. A high-power, relatively inexpensive lens fitted in a spectacle frame can be used for reading. The best correction can be used for ordinary travel. These two corrections can be combined in a bifocal lens, if such is desired. If a nearly blind person wishes to see something like a street sign, he can use a pocket telescope such as the "penscope," available through the American

Foundation for the Blind, 15 W. 16th St., New York 11. For sports events, some patients like to use low-power binoculars. Before any special lenses are fitted, a person should have a thorough ophthalmological examination. Apparently the "tri-optic lens" is available only through its inventor.

CAUSE OF OLD INFARCT

To the Editor:—*A man, aged 29, has an old healed infarct of the anterior coronary branch without any significant history other than that he was temporarily paralyzed at the age of 9 by a bolt of lightning. Clinically, he is quite well. Could this accident have damaged the vessel?*

Malcolm L. Raymond, M.D., Johnstown, Pa.

Answer.—A generalized electric shock should not have a selective effect on a coronary branch. At the age of 9 years, atherosclerotic damage is not likely. It is possible to have a relatively painless infarction of a coronary branch. The patient's pain threshold would be a factor.

TREATMENT OF HEPATITIS

To the Editor:—*In a recent issue of a German medical publication,* Drug Research, *an article appeared on the treatment of different forms of hepatitis by means of a substrate consisting of supravital liver cells coupled to a bacterial haptene. Please comment on this type of therapy.*

Emily A. Svoboda, M.D., Chicago.

Answer.—The variable and unpredictable course of any given case of hepatitis has led to claims for many forms of therapy which further experience has shown to have been unfounded. The use of "supravital liver cells coupled to a bacterial haptene" has no rational basis, nor is there any convincing evidence of its efficacy. For the present, reliance on generally accepted symptomatic and supportive measures for the treatment of hepatitis is indicated.

NUTRITION FOR A PATIENT WITH TWENTY CENTIMETERS OF JEJUNUM

To the Editor.—*An additional therapeutic measure to those that were offered in the Questions and Answers column on the subject of nutrition for a patient with 20 cm. of jejunum* (J. A. M. A. 169:*201 [Jan. 10] 1959) is the use of corticosteroids. We have given prednisone (and before that cortisone) with much success to patients with jejunoileitis who have undergone massive resection. The usefulness of corticosteroids lies in their ability to increase the absorption of fluids, electrolytes, and nutrients from the intestines. The dose may vary from 15 to 30 mg. of prednisone per day. This should be fortified at monthly intervals by ACTH and, in this case, by a male hormone. Despite the colostomy, the administration of steroids should be rewarding. The use of the term regional ileitis for such extensive disease requires some elaboration. Ileocolitis, regional enteritis, and nonspecific jejunoileitis are more precise terms.*

Hackensack, N. J.

SMALLPOX VACCINATION

To the Editor:—*An item in Questions and Answers (J. A. M. A.* 169:*198 [Jan. 10] 1959) stated that failures to develop a primary take of smallpox vaccination were due to faulty vaccination technique or to the use of vaccines which had lost their potency because of improper or prolonged storage. A woman has had repeated vaccinations for smallpox without a take. Vaccinations have been performed by a number of physicians, including myself, with vaccines that had proved effective in other patients. A son, aged 2½ years, also has had repeated vaccinations without a take. A daughter, aged 10 months, has had a successful take. I am wondering if others have had similar experiences and if other factors in the take of smallpox vaccination are to be considered.*

Horace A. Deford, M.D.
34th Air Division (Defense)
Kirtland Air Force Base, N. Mex.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*Experimentally it has been shown that the state of nutrition and hormone balance of an animal affects the growth of vaccine virus and the lesions it induces (Smadel, in Viral and Rickettsial Diseases of Man, edited by Thomas E. Rivers, Philadelphia, J. B. Lippincott Company, 1952). In man it may be that due to these or other factors some persons are truly resistant—at least temporarily—to smallpox vaccine. There is, however, evidence that such persons are rare and, for the most part, repeated failures to take are due to a faulty technique or to the use of an inactivated vaccine. The fact that a particular lot has proved successful in other patients does not necessarily mean that it should also be successful in a particular individual. As stated by Leake (Questions and Answers on Smallpox and Vaccination, Public Health Report, reprint 1137), "differences in skin receptivity may occur independently of the condition of the individual as regards true immunity. . . . Some individuals may be resistant . . . to a lot of vaccine which gives success generally in other individuals, but are not immuned against smallpox when exposed, nor against vaccination when a fully potent lot of vaccine is used."*

EFFECTIVE SYSTEM OF BACTERICIDAL CONDITIONING FOR HOSPITALS

Perry B. Hudson, M.D., Grant Sanger, M.D.
and
Edith E. Sproul, M.D., New York

Control of the hospital environment is an important initial step in the campaign to control hospital infections. Daily treatment of the patient's entire environment with chemicals is not feasible, but bactericidal treatment of the air can and must be continuous. Four materials are here described for use as waxes, in floor preparations, and on air filters; for application as wax to metal and glass; for spraying walls, ceilings, floors, and mattresses; and for laundry, furniture, and draperies. Their effectiveness was studied in a comparative experiment in which alternate wards in a hospital were studied bacteriologically, the air being recirculated at various set rates. It was found possible to bring about a steady reduction of the bacteria in the air without depending on a central air conditioning system. A major portion of the bacteriological killing depends on procedures other than air filtration. The methods suggested were found consistent with ordinary hospital housekeeping techniques.

An increase in mortality and morbidity from infections in hospitals is attributed to dissemination of bacteria which are resistant to antibiotic drugs. Most prominent among the resistant strains of bacteria is the coagulase-positive Staphylococcus aureus (80/81 strain). The serious nature and wide currency of the staphylococcic infection problem has been emphasized at large conferences held specifically for discussion of this topic. The problem is now of sufficient magnitude to demand the establishment of infection committees in all institutions within which sick persons are housed.

The committee on infections in the Francis Delafield Hospital made a decision to undertake control of the hospital environment as an initial step in its campaign to control hospital infections. For this purpose it has been necessary, first, to define precisely the elements comprising the hospital environment; second, to find the proper agents to be used in the control of the environment; third, to conduct controlled experiments utilizing the agents and methods selected; and, fourth, to evaluate objectively the altered environment.

Hospital Environment

The hospital environment is defined in a personal rather than a geographical way. The person in relation to whom this definition is made is the patient. His environment is made up of a multiplicity of contributions from all of the persons, things, and mediums with which he has contact.

From the departments of urology, pathology, and surgery, Francis Delafield Hospital, Columbia-Presbyterian Medical Center.

The air in which the patient moves and which he breathes is a principal element of the environment. The persons and things which both the patient and the hospital air touch contribute to the total constitution of the environment.

The relative importance of any portion of the environment depends on the intimacy, frequency, and duration of contact which the patient may have with that particular unit. The air and linen supply for patients probably exceeds in relative importance the bacterial flora on a ceiling. On the other hand, even bacteria on a ceiling assume importance when and if they enter the ocean of air to which both the patient and his linens are exposed. Food as well as its preparation was deliberately omitted from this experiment.

Formulations Used in Removal of Bacterial Contamination in Hospital

Formulation A (for waxes, floor preparations, and air filters)	%
Silver nitrate	1.32
Ammonium thiocyanate	1.32
Triton X45	5.04
Hycryl A-1000	26.01
Poloco 380	33.61
Nuodex 100	0.35
Propylene glycol	0.32
Water	32.03
Formulation B (for metal and glass wax)	
Dialkyl*dimethyl ammonium chloride	0.0214
o-Hydroxybenzoic acid	0.0140
Bis(n-tributyl) tin oxide	0.0151
2,3,5-Triphenyl-2,1,3,4-tetrazolium chloride	0.0015
2-Amino-2-hydroxymethyl-1,3-propanediol	0.0168
2-Hydroxyethyl tetramethyl ammonium chloride carbamate of zinc chloride	0.0105
Dimethylcarbinol	0.0216
Neutroleum gamma	0.0008
Inert ingredients	99.8982
Formulation C (spray for walls, ceilings, floors, mattresses, and laundry)	
Dialkyl*dimethyl ammonium chloride	0.0214
Salicylic acid	0.0140
Bis(n-tributyl) tin oxide	0.0151
Inert ingredients	99.9495
Formulation D (spray for laundry, furniture, and draperies)	
Salicylic acid	0.0301
Arquad 2C-75	0.2064
Neutroleum gamma	0.0273
Bis(n-tributyl) tin oxide	0.0325
Isopropanol 99%	0.0957
Spice bouquet	0.0082
Inert ingredients	99.5998

* Alkyl groups as in the fatty acids of cocoanut oil.

The bacterial populations in the respiratory system and on the skin of patients, hospital staff, and visitors are considered to be an uncontrollable portion of any patient's environment. They are also unpredictable. Therefore, removal of bacterial contamination, not simply detection of human carriers per se, is one of the prime objectives in the design of an environmental control system. This concept is important in our program for bactericidal conditioning of hospitals. The hospital has been changed from a repository for germs into a self-decontaminating area. These alterations in environment have been achieved by the addition of bactericidal substances and by removal of bacteria.

Agents and Methods

The difficulty in selecting bacterial substances was one of finding drugs of lasting germ-killing properties. Daily treatment of the patient's entire environment with chemicals is not feasible. It is also acknowledged that the bactericidal treatment of air must be continuous.

The low-cost, long-lasting bactericidal properties, ease of applicability, wide-range spectrum response, and low toxicity of the agents finally selected were decisive factors. A list of these formulations is contained in the table. Bactericidal conditioning was designed for both efficacy and duplicability in other hospitals.

At the laundry, hospital linens were treated by addition of bactericide to the rinse water for sheets, towels, blankets, pajamas, curtains, and staff uniforms. The concentration selected was such that substantivity would be maintained only until the next washing cycle. A more permanent effect (for example, for the life of blankets) can be obtained by using materials impregnated with the bactericide at manufacturing levels. However, in order to achieve the variable control essential for this experiment, the laundry technique was used.

Ceilings and walls of each ward, ward corridor, utility room, lavatory, and solarium in the patient areas were washed and then sprayed with a bactericide. Waxes for glass, furniture, and metal were prepared with added bactericide. Every article within patient contact was either washed or sprayed with one of the bactericidal formulations. Mattresses and pillows were sprayed and then covered with bactericidal plastic covers. All covered areas such as radiator shields and ducts were opened, cleaned, and sprayed. The floor wax contained bactericide preparations. Routine floor care followed, with bactericide added to the mop water.

The hospital air was controlled as follows: Patient areas were under positive pressure, and areas of known, continual infection were subjected to negative pressure with external exhaust. Exhaust fans were also placed at one end of the ward corridors. Fresh air intake window fans were placed in each ward. Air recirculation was maintained in the wards, corridors, and solariums by means of small recirculation units for bactericidal filtration. Window input and recirculation units contained double filters impregnated with bactericide. The total volume of air was recirculated once every 10 minutes (that is, recirculation time equals 10 minutes, or RT=10). This recirculation time (RT) was varied as the experiment progressed. Filters were changed on a cosmetic rather than germicidal basis, since the former preceded the latter need by some weeks. After the initial stage of preparing test areas, bactericide was used only in mop water, water used to wipe off furniture, and aerosol spray bombs for spot disinfection purposes.

Hospital Experiment

The Francis Delafield Hospital is a 300-bed general cancer hospital staffed by Columbia University and administered by the city of New York. Its general plan is indicated in figure 1. The hospital contains no central air conditioning plan or equipment.

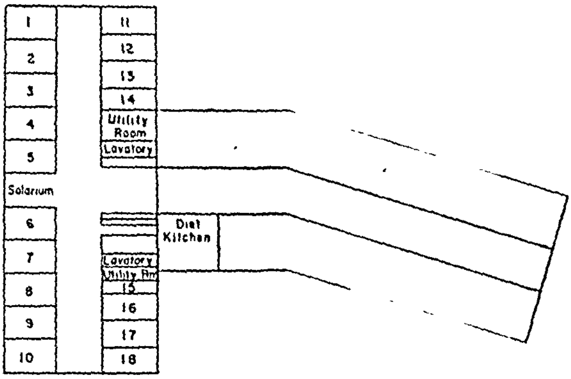

Fig. 1.—General plan of Francis Delafield Hospital. Second, third, fourth, and fifth floors have 40 six-bed wards, 10 to each floor (areas 1 to 10 in diagram), which constituted the test and control areas studied. Areas 11 to 18 are two-bed or three-bed rooms.

General Bacteriological Evaluation of Hospital Environment.—For three days, consecutive culturing was done in all patient and service areas, by streak, poured plate, and open dish methods, which included fomites as well as air. Culture tubes and plates were marked by number. Colonies were counted and identified by the hospital bacteriological staff, who did not know the origin of the cultures. Results were entered by code in log books, the key to which was held by one member of the committee on infections. A number of potential sources of infection were discovered, but no changes were made in the hospital routine throughout the course of all the experiments.

Air samples were collected on opened, preincubated Petri dishes containing sterile nutrient agar. Exposure time was one hour. Cultures were made during times of day when average patient and visitor activity was in progress. Cultures were incubated at 37 C for 20 hours. Bacterial colonies were counted with the Quebec dark-field counter and a four-power lens.

Colonies resembling Staph. aureus were reincubated at room temperature for two days and reexamined for pigment production. For all cultures the bacteria were identified by colony characteristics and by microscopic examination of Gram-stain smears from individual colonies.

Staphylococcus colonies were replated on sheep blood agar medium, and the presence of hemolysis after incubation was recorded. Coagulase tests were also performed on these strains. The penicillin impregnated disk method with 18-hour culturing on agar plates was used to determine antibiotic sensitivity or resistance. (Detailed studies on organisms other than staphylococci will be published elsewhere.)

Preliminary Control Experiment.—The statistical consultants for the hospital experiment requested that it be conducted on the basis of alternating wards as controls and as bactericidally conditioned areas on each of the four inpatient floors (fig. 2). After this recommendation, alternate wards were treated by the methods previously described. For control wards, only routine hospital procedures were used, except that the same type of window input and air recirculation fans were installed to keep air procedures similar. Air control for this experiment consisted of filtration of the locally recirculated room air once every 10 minutes (RT=10).

In order to use the alternate ward system, it is necessary to maintain closed doors between the bactericidally conditioned wards and the alternating control wards. Both ambulatory patients and hospital staff personnel have easy access to these doors in our hospital. Closure of the doors for many weeks would be required for evaluation of altered population of bacteria in the air of the conditioned areas.

The committee on infections was unable to secure the level of cooperation needed for full evaluation of this checkerboard technique. Nevertheless, alternate ward conditioning did result in an average 50% decrease of colony counts in air of conditioned wards. Experience with this alternate ward experiment has reemphasized the need for bactericidal conditioning, agents, and methods which are consistent with routine hospital housekeeping measures and which require little or no change in habits or therapeutic techniques.

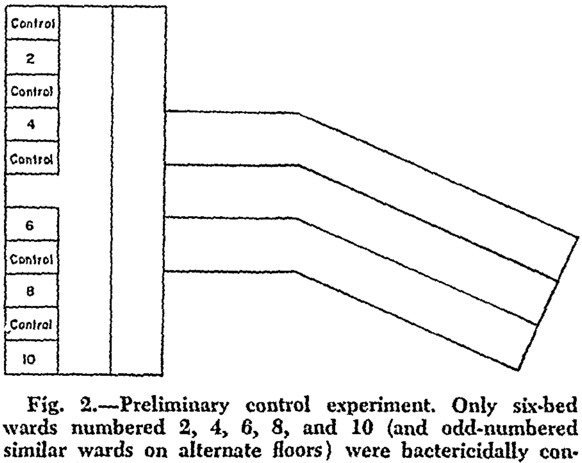

Fig. 2.—Preliminary control experiment. Only six-bed wards numbered 2, 4, 6, 8, and 10 (and odd-numbered similar wards on alternate floors) were bactericidally conditioned. Doors permit not only control ward air but also contaminated corridor air to enter each conditioned ward whenever door is opened.

Long-term Forty-Ward Hospital Experiment.—After the preliminary experiment, two patient floors were completely exposed to bactericidal conditioning. Wards, solariums, utility rooms, lavatories, and diet kitchens were washed and sprayed, and air control measures were instituted in these areas as well as in ward corridors.

As the experiment proceeded, changes were made in the air control measures. Principally this consisted in working out better exhaust techniques to control negative pressure areas with more efficiency and less noise, while recirculation times within the patient wards were raised and lowered to find the exact point of bactericidal control in the presence of the most extreme conditions of contamination. Simultaneously, this afforded an opportunity to ascribe relative importance to air control measures and the other means of bactericidal conditioning.

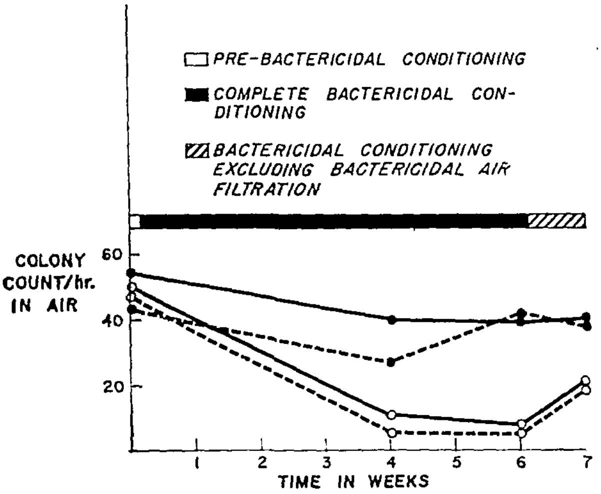

Fig. 3.—Effect of bactericidal action on hospital environment. Each point on graph is average value of 60 air cultures. Duplicate cultures in all 10 of six-bed wards on all four floors were made for three consecutive days; thus, 60-culture average of each floor has been made. Lines with black circles represent control floors; with open circles, test floors.

After complete conditioning of the two floors, they were designated as test floors; the remaining two patient floors were used as controls. It was recognized that the previous checkerboard treatment applied to the control floors would tend to lower their total bacterial counts and apparently lower the system's efficacy. This was accepted as a condition of the experimental control.

Air cultures were made on each floor daily, with two cultures to each ward room. Culturing was done in corridors, solariums, isolation rooms, and nurses' stations. At intervals, surface and fomite cultures were also taken.

All Petri dishes were identically placed during the experiment, one near and to the right of the corridor door, the other to the left and near the far window. Exposure time was one hour at varying intervals ranging from maximum visitor exposure to late night quiet. Culturing for final evaluations was done during evening visiting hours.

Results

Long-term Forty-Ward Experiment.—The effect of long-lasting bactericidal action on the hospital environment as interpreted through air cultures is shown in figure 3. The initial values (in colony counts) on the control floors were 54 and 43; those on the test floors, 47 and 50. Four weeks later, the control floors had values of 27 and 40; the two bactericidally conditioned floors yielded air counts of 5 and 11 respectively. One and one-half months after bactericidal conditioning, the control floors were found to have counts of 39 and 43, while the test floor counts were 5 and 8, a reduction of 87 and 82% respectively.

It next seemed desirable to ascertain the relative value of the main components of the system used to accomplish this result. The last point on each of the four graphs in figure 3 represents the average cultures one week after the bactericidal agents were deleted from the air filtration process. The remaining decrease in bacterial colony counts on the test floors (to 18 and 20 respectively) below the control values (38 and 40 respectively) is attributable to components of the bactericidal conditioning process other than those directly applied to air.

Approximately two-thirds of the bactericidal effectiveness in this experiment may be attributed to elements of bactericidal conditioning not related to bactericidal filtration of air. Under conditions of extreme contamination of air, the relative value of bactericidal filtration increases somewhat.

Laboratory Model for Comparing Effectiveness of Bactericidal Conditioning Systems.—Early in our studies of hospital environmental problems related to pathogenic bacteria, the need for a model designed to approximate physical conditions encountered in a hospital building was apparent. It is useful in rapid screening for bactericidal efficacy of a large number of substances. Models also permit study of various methods of use for the selected bactericidal agents.

Our hospital model is similar to a bacteriological transfer chamber. It has six sides, is hermetically sealed, and contains 27 cu. ft. of space. This chamber is equipped with walls which are easily sterilized and which can be coated with various types of bactericides. It is furnished with an air recirculation machine which can optionally be equipped with different types of filtration devices.

The experiments in the model system have included the 80/81 strain of coagulase-positive, penicillin-resistant Staph. aureus. The details of four such experiments with this micro-organism are as follows: The principal point of reference quantifying the efficacy of agents and techniques is the rate of disappearance, over a period of two hours, of known numbers of specific micro-organisms grown in pure culture. The recirculation rate for all the experiments described here is one volume of air every four minutes (RT=4).

For experiments A, B, C, and D, two billion staphylococcus organisms were nebulized into the model hospital chamber in a single injection at the time recorded "0" for not more than two minutes' time. Experiment A consisted of simple recirculation without bactericidal coating of the walls and without bactericidal filtration of the air of any sort (control experiment). Experiment B consisted of filtration of the recirculated air through a synthetic fiber filter not containing bactericide; walls of the chamber were not coated with bactericide. Experiment C consisted of bactericidal filtration of the recirculated air; walls of chamber were not treated with bactericide. Experiment D consisted of bactericidal filtration of recirculated air; walls of chamber were coated with bactericide (see table).

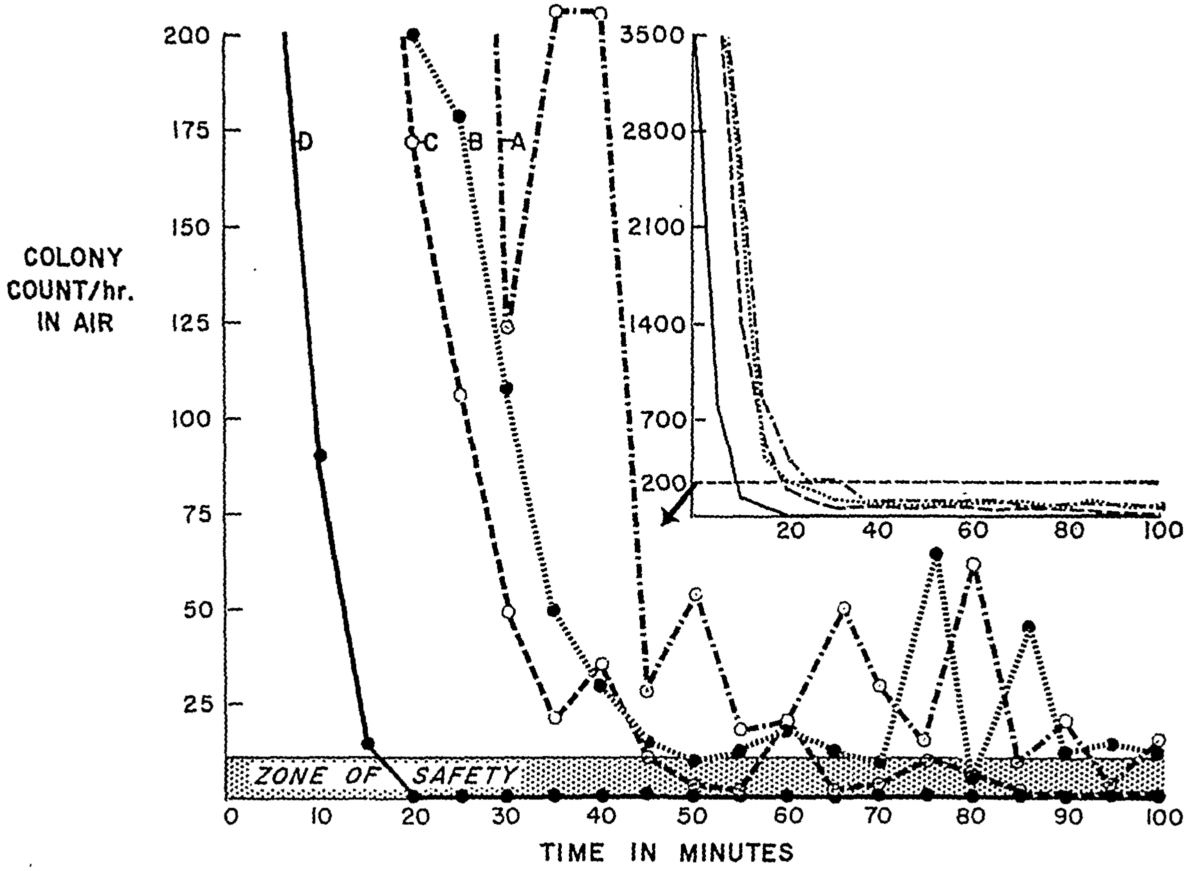

Fig. 4.—Colony counts in control and three experimental situations established in model chamber. Graph *A* is control; *B* represents serial counts when ordinary commercial filter is used; *C* shows effect of bactericidal filter without any other part of system; and *D* is model of hospital system found most effective—a combination of bactericidal filtration of air and bactericidal treatment of all surfaces.

Petri dishes used for air cultures in experiments A, B, C, and D were exposed for periods of five minutes each to cover, in duplicate, the entire period of two hours during which experiments in this model were run. The model chamber is equipped with built-in gloves long enough to permit remote, sterile handling of culture dishes throughout the experiments. The cultures could in this way be opened for specific five-minute intervals throughout the total time of the experiment so that cultures were done for consecutive five-minute periods.

The results of experiments A, B, C, and D are shown graphically in figure 4. For our model, as was the case with the hospital building, an upper limit of 10 colony counts for relative bacteriological safety was adopted. For the model system, the five-minute exposure periods are equated in the time-space scale to equal one hour. Therefore, the time required for reduction of the viable recirculated Staph. aureus suspended in air in these four experiments is the main criterion on which comparison of the different bactericidal techniques is based.

In experiment A (control), viable Staph. aureus organisms were erratically collected at dangerous levels of concentration throughout the entire experiment.

Similarly, in experiment B, viable organisms were collected, in somewhat lesser numbers, at dangerous levels throughout the course of the experiment despite use of an ordinary air filter.

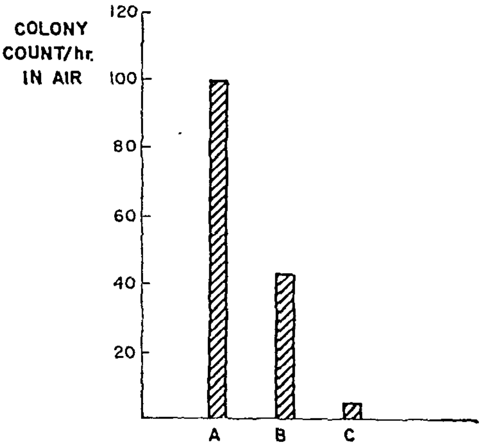

Fig. 5.—Colony counts. *A,* changing of ordinary, laundered blanket in ordinary hospital room yields level of 100 colony counts per hour. *B,* level of 43 results when bactericide-treated blanket is changed. *C,* only 5 colonies per hour are deposited when both room and blanket are bactericidally conditioned.

The bactericidally conditioned air filter used in experiment C produced a bacteriologically "safe" atmosphere in 45 minutes' time. At 65 minutes, a secondary rise to a level of 20 counts resulted. After 65 minutes, there is no return to levels above 10 counts. The zero mark was first reached in the 80-85 minute sample.

Experiment D was a model of the system finally adopted for our hospital bactericidal conditioning program. After the 15-minute sample, all of the culture plates failed to grow Staph. aureus.

This striking result gives objective support to the decision which resulted in the selection of agents applied in the fashion represented in experiment D for use in the actual hospital situation.

Corollary Hospital Experiments.—Our studies of the effectiveness of the bactericidal conditioning system included determination of the contributions from both persons and things to the population of pathogenic bacteria in the hospital air.

Hospital Blankets: A three-stage experiment on hospital blankets was performed. During the culturing period of one hour, no activity in the room was permitted. At the midway point in time, the blanket was stripped from the bed, turned over, and tucked around the mattress with the head and foot reversed. The blankets in each experiment were taken from the hospital linen supply immediately on return from the laundry. Activity was again forbidden for the remainder of the culturing period.

As shown in figure 5, when this procedure was followed in a two-bed ward room with a laundered blanket without bactericidal conditioning of the air, blanket, or room surfaces, a culture colony count of 100 was obtained. When this experiment was repeated in a room having no bactericidal treatment of either fomite surfaces or air, with a blanket bactericidally treated in the laundry, the colony count was 43. The third stage involved a bactericidally conditioned blanket and a room which had been given the same conditioning of air and surfaces as carried out in the hospital during the main experiment. The colony count then was 5.

Patients with Staphylococcic Infections: Figure 6 illustrates an experiment in two two-bed wards. Before bactericidal conditioning the air in each of these wards averaged 42 colony counts. After bactericidal conditioning they remained near zero for three weeks. Two patients, one with a mouth lesion and one with furunculosis of the shoulder (both of bacteriologically proved Staph. aureus origin), were admitted to room A. The recirculation factor was RT=10. After two days of high counts in room A, the patients were shifted to room B. Within six hours, room A, despite a high degree of personnel activity, was decontaminated to zero. In two days the air colony count in room B rose to 113.

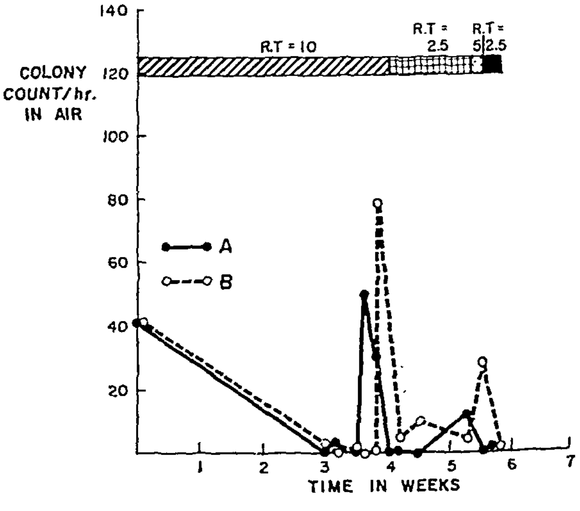

Fig. 6.—Effect on colony counts when patients with staphylococcic infections moved from room A to room B near end of fourth week. Note rapid fall-off of counts in room B when recirculation time (RT) decreased from 10 to 2.5 minutes.

At this point recirculation time was changed to RT=2.5. The air colony count dropped to 5 within six hours.

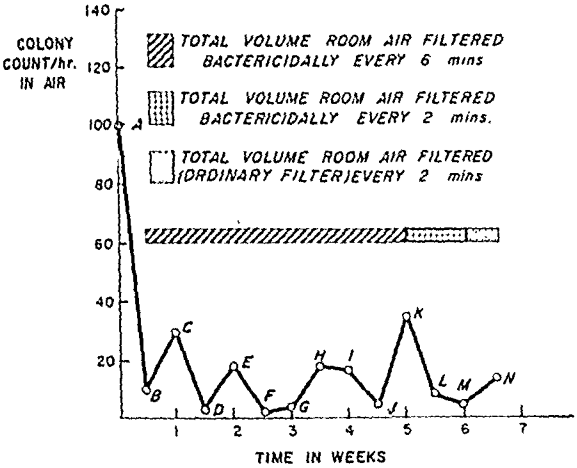

Fig. 7.—Continuous study of cultures. *A*, prebactericidal conditioning; *B*, bactericidal conditioning (checkerboard); *C*, door open to contaminated corridor; *D*, all wards bactericidally conditioned; *E*, door open to contaminated corridor; *F*, corridors bactericidally conditioned; *G*, door open to bactericidally conditioned corridor; *H*, four resident physicians examining patients; *I*, enema administered; *J*, normal ward activity; *K*, tracheostomy patient admitted to ward; *L*, normal ward activity; *M*, normal ward activity; and *N*, reversal experiment (bactericidal air filtration discontinued).

During the fifth week of this experiment, single bactericidal filters were substituted for double filters. The rise in air colony counts for both rooms prompted a return to use of double bactericidal air filtration. Colony counts immediately decreased again. In the middle of the sixth week, the recirculation time in room B was changed to RT=5. The count immediately rose to 28. The next day it was changed back to RT=2.5, and the count dropped to 2. Room A in the meantime remained at zero, except for the period when single filtration was attempted.

Continuous Gross Air Contamination: Study of the cultures taken during the course of many experiments indicates that the highest level of contamination contributed by patients is from male tracheostomy patients. Gross contamination from such patients has been demonstrated at a distance of 14 ft. from the patient. As shown in figure 7, the air recirculation utilized was RT=6 up to point K, when a male tracheostomy patient was admitted to the ward. The colony count then rose to 35. The RT factor was changed to 2, with a decrease in the count to 7 and then 4, in one week's time (points L and M). The rise at point N was due to the cessation of bactericidal air filtration during the "reversal" phase of the experiment.

During a three-week period a study was made of a six-bed ward to which patients were admitted with colostomies (2), an infected neoplasm of the lung, a rectovaginal fistula, a urinary tract infection, and a salpingo-oophorectomy. The problem of odor as well as air contamination was considered to be important. Details of this study are seen in figure 8.

Comment

The air control system finally adopted is shown in figure 9. It will be noted that the corridors are bactericidally conditioned and are included in the air control plan. Throughout our experiments of the last several months, it has been shown repeatedly that it is necessary to have an air lock adjacent to the patient areas in which the lowest possible contamination is sought. This measure prevents chance contamination of the air in the wards when doors are opened.

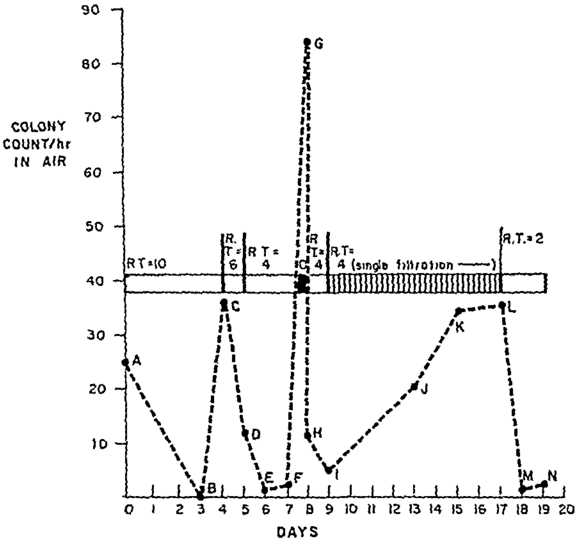

Fig. 8.—Study of odor problem. *A*, only patients with salpingo-oophorectomy and urinary tract infection in ward; *B*, bactericidal conditioning of ward; *C*, two colostomy patients and one lung cancer patient admitted to ward; *D* and *E*, recirculation of air changed to 6 and 4 minutes respectively; *F*, no change in conditions; *G*, bactericidal air filtration completely discontinued; *H*, 3 hours of reinstitution of air recirculation at RT=4; *I*, continuing low level of 5 counts; *J*, patient with rectovaginal fistula admitted; *K*, continuing rise in air colony counts during period of single-filter bactericidal filtration of air; *L*, high point before institution of double filtration of air with bactericidal filters and recirculation every 2 minutes; and *M* and *N*, levels maintained by double filtration at RT=2 even though no contaminating elements from patients have been altered.

It is readily acknowledged that great emphasis has been placed on the role which hospital air plays in making the environment either safe or dangerous. As Blowers and associates[1] have demonstrated, there is a direct correlation between surgical infection rates and air contamination. In addition, they have shown that the Staph. aureus carrier rate among both hospital patients and staff members decreases with a decrease in the degree of air contamination.

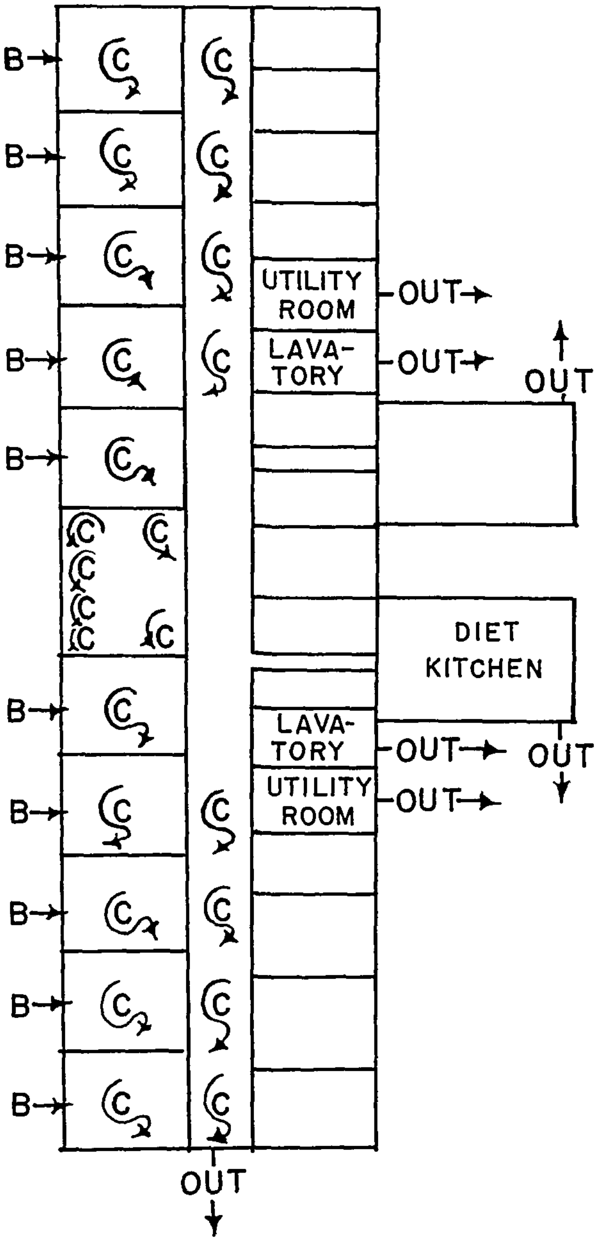

Fig. 9.—Air control system finally adopted. *B* indicates air intake window unit containing double bactericidal filter. *C* indicates interior recirculating fans with double bactericidal filters. All points labeled "out" are external exhaust fans.

On the other hand, the importance of inanimate objects in harboring bacteria has been elucidated by Walters.[2] His statement that "blankets are reservoirs and spreaders of bacteria in many hospitals" has prompted the blanket experiment included in the body of this report.

Our purpose has been to develop a system which utilizes commercially available substances and requires equipment useful in existing hospital buildings which are not centrally air-conditioned. The agents which we have used have been low in cost and have been used successfully. "Success" has been defined in terms of decontamination of the hospital environment as it is defined here in such a way that the basic conditioning process will probably not have to be repeated more than four times annually. That the hospital air must be continuously treated is an obvious fact. However, the removal of excessive contamination by means of variable control of the air recirculation rates through double bactericidal filters provides a flexibility in the sytem which it would otherwise lack.

The effect on the hospital environment through the use of the bactericidal formulations selected for the Francis Delafield Hospital experiments has been obtained because of the long-lasting bactericidal properties of the formulations used.

Summary

The current problem of hospital-acquired bacterial infections is believed to be a function of contamination in the patient's environment. Long-lasting bactericidal agents have been tested and found practicable and safe in hospital use. Hospital and laboratory experiments with these agents have been successfully conducted. More than four-fifths of the bacteria in air can be removed by the use of a combined air-and-fomite system of bactericidal conditioning. The agents and techniques for bactericidal conditioning are commercially available and reasonable in cost. Bactericidal control in hospitals is not dependent on a central air conditioning system. Bactericidal filtration of air without inclusion of other measures is not sufficient for an optimal result. Bactericidal conditioning is consistent with ordinary hospital housekeeping techniques.

99 Fort Washington Ave. (32) (Dr. Hudson).

All of the bactericidal agents used in the hospital and laboratory experiments were formulated and supplied by the Permachem Corporation, New York.

CONTROL OF INFECTIONS WITHIN HOSPITALS

SPECIAL REFERENCE TO PREVENTION WITHIN OPERATING ROOMS

and
Stanley Read, M.S., Wolfeboro, N. H.

A searching study of hospital infections showed that blankets, shoes, the bottoms of trousers, straw brooms, dry mops, and certain types of vacuum cleaners were important spreaders of infection. It was found that the surgical area could be cleaned up and would remain clean until contamination was introduced. Personnel could learn so to conduct themselves with respect to masks, clothing, and shoes that they would not introduce contamination. An interchange zone was developed to separate the surgical area from uncontrolled areas, and a sexless, sizeless, reversible gown and improved footwear were adopted to facilitate changing when personnel are obliged to pass from one area to another. A fitted filter autoclavable mask was devised to prevent contamination of clean room air by respiratory exhalations of personnel or patients. If deep-seated wound infections with resultant systemic manifestations are to be prevented, the ultimate in asepsis must be attained, and no leniency can be tolerated.

Three years ago a study was launched into causes for infections occurring within Huggins Hospital and methods for prevention. This work has continued actively to date. Two years ago it was realized that nearly any patient who had entered the hospital clean during the preceding year and who had contracted an infection while there was the victim of an error in technique.[1] These errors include prophylactic use of antibiotics and steroid hormones used nonspecifically, but infection incidence in this hospital is influenced by these two factors only as they may have been induced by self, druggist, or practitioner administration to patients before they were hospitalized.

The most fundamental fact regarding the broad problem of infections occurring within hospitals is that clean or healthy tissues become infected because they are exposed to infectious agents at a level of virulence, concentration, or frequency of exposure beyond their resistive powers. Here in this fact, experience indicates, lies a practical approach to control measures. If reduced to axiomatic form, the fact would read: Where there is no contamination of healthy tissues, there is no infection. Restated in procedural terms, it would read: When necessary standards of sanitation and care are practiced in the protection of tissues from contact with infectious organisms, almost no infection will occur. The problem is one of cleanliness—how to attain it, and how to maintain it.

This article is a report of investigations made into the causes of infections in Huggins Hospital and a description of a control program which has now been proved to be medically effective, practical, and economically feasible. The studies were made primarily because of seven wound infections that occurred in the course of 356 operative procedures after establishment of protective measures previously but erroneously thought to be adequate.

Attainment of Cleanliness

Daily tests were done over a period of six months to determine the effectiveness of mechanical and antiseptic cleanliness in reducing bacterial contamination of rooms. One series of tests was done in adjacent rooms subjected to steady and parallel usage. Cultures were taken in multiple areas of each room, with the location known only to the bacteriologist, and these were made without any preliminary preparation. Sieve sampler techniques were used for air sampling; swab and flush washing techniques were used on furniture, walls, and floors. Room 1 was then given daily the most thorough mechanical cleansing that a good workman could apply, including ceiling, walls, floors, and every item in the room. He used a detergent selected by himself at a local store. Each succeeding day for a week he bought and used a different one. His work was supervised and directed by a nurse with long experience, a known eye for dirt, and a perfectionist attitude of abhorrence for a speck of dust. In room 2, the type of cleaning supplied by the housekeeping department was continued. It should be added that the hospital has held a good public reputation locally for being a clean and neatly kept institution.

Professor of Clinical Surgery, Boston University School of Medicine, and Chief, Division of Surgery, Huggins Hospital (Dr. Adams); Bacteriologist (Mr. Fahlman), Directress, Sanitation Control Program (Mrs. Dube), Anesthetist and Physician (Dr. Dube), and Administrator (Mr. Read), Huggins Hospital.

Immediately after each room was cleaned, cultures again were taken from the same areas. Usage of both rooms continued actively throughout the day and night. Eight and 24 hours after cleaning, cultures were taken from the same areas. The rooms were similarly cleaned and tested on the second day, and the program was continued each day for seven days.

For a second week, two wards which were subject to similar usage were selected, and this experiment was repeated without variation, except for one detail. The cleaning solution used was an excellent detergent-disinfectant (Tergisyl), a concentrated solution of sodium xylene sulfonate, triethanolamine dodecyl benzene sulfonate, *o*-phenylphenol, and *p*-tertiary amylphenol. It was supplied as a 2% solution and without limitation as to amount available, both to the highly competent, especially supervised workman and to the routine workers of the housekeeping department. In subsequent one-week periods, these parallel tests of cleaning procedure and effectiveness were run on two corridors, two dressing rooms, two kitchen and dining areas, two utility rooms, two linen preparation rooms, and two operating rooms. Both test areas had the same detergent-disinfectant solution used, not only by the extremely good but also by the ordinary cleaning personnel. In fact, after the third week the detergent-disinfectant solution was adopted as the only one for every cleaning procedure in the entire hospital, not only because it was a good preparation but also in order that there might be no prejudiced factor unwittingly introduced by variation in cleaning solutions.

Analysis of these accumulated data brought out several facts convincingly. Thorough mechanical cleaning has a demonstrable, dramatic, and almost immediate effect in the reduction of bacterial contamination. This reduction progresses with daily repetition of the process. There is a slight to moderate residual effect from the cleansing over a succeeding period of several hours. Casual, superficial, and unintelligently supervised cleaning has scarcely any demonstrable beneficial effect in reducing the amount or type of bacterial flora. When an efficient detergent-disinfectant compound is added to a good mechanical cleaning process, there is an obvious residual effect that can be demonstrated bacteriologically on cultures taken as long as eight hours after previous cleaning. From these many weeks of comparative studies, there emerged an important facet of truth: By a procedure of frequently repeated, intelligently directed, and vigorously applied mechanical effort in combination with a good detergent-disinfectant, any surface or area whatever can be rendered clean or even sterile.

There were additional observations. The wards were the dirtiest. The private rooms were the cleanest. Blankets are a constant source of contamination and will spread micro-organisms from one patient to another promptly if blankets are moved from one bed to another or if patients are put into beds that are not provided with freshly sterilized, clean blankets.[2] So also will contamination be transferred by a blanket to an operating room if it is allowed to go with the patient from his bed to that room. One can render washed bankets uniformly sterile by addition of a 2% concentration of *o*-phenylphenol and *p*-tertiary amylphenol (Amphyl) to the final rinse of the laundry washing cycle. Ordinary mops and cloth rags are little more than culture mediums for bacteria unless they are frequently and thoroughly cleansed in a detergent and disinfecting solution. Straw brooms and dry mops and dusters, like ordinary vacuum cleaners, are essentially dispersing agents for bacteria, and the use of all of these items should be prohibited in hospitals.

Although hot water plus a good detergent-disinfectant makes an excellent cleaning solution, it has been shown to become infected with viable organisms unless the solution is changed frequently enough to avoid development of a dirty appearance. Laundry hampers, as used in standard practice, are filthy, but they can be readily sterilized before being used to receive clean laundry. The best routine is the requirement that they be turned upside down and washed out with a detergent-disinfectant solution, but laundry workers will not cooperate with this regulation except when forced to it. Additionally, the hampers should be lined with paper before receiving clean laundry for return from the laundry department. The latter regulation can be enforced without difficulty. The chutes down which the laundry is dumped in Huggins Hospital, and presumably in most hospitals,[3] are heavily infected. If doors on two floors are opened simultaneously, the chutes become wind tunnels which blow contaminated air out through the porthole doors into the corridors. Vertical laundry chutes are a menace bacteriologically for which no satisfactory solution has been found.

Abundant evidence from hundreds of cultures shows that, where there are large numbers of patients present and people in attendance to these patients, the level of air pollution rises, and markedly in some instances. Regardless of how intensive the clean-up effort is or of the observation that cultures taken immediately after a thorough clean-up show the number of organisms present to be reduced substantially, there is a rapid and stepwise build-back of the total numbers recoverable from exposed surfaces in a room after a period of time. The evidence also indicates clearly that air pollution is related to the amount of dust about any one area and that air pollution can be greatly reduced by effective housecleaning. It is hard to reduce and maintain in reduced form the number of organisms present as fomites when there are patients and visitors congregated in an area. However, it is possible to reduce the number of airborne organisms by the removal of dust, and, by so doing, one removes a vehicle for transportation of these organisms widely throughout a room. When people in ordinary clothing and uniforms are admitted, evidence of contamination both of the surfaces and of air rapidly rises in a room, no matter how carefully it has been cleaned previously or how short a time beforehand the cleaning was done. The rate and amount of rise are proportional to the amount of visible dirt and dust and to the volume of usage.

Maintenance of Cleanliness

The subjects which must be considered in maintenance of cleanliness are personnel, room air, masks, clothing, shoes, equipment, supplies, and procedures. A series of experiments were run in a room which had been brought previously to near-sterile conditions by an ultimate type of cleaning procedure, to which only filtered noncontaminated air was being introduced, and it was delivered to the room at a pressure which caused all air flow from the room to be outward. Observations from these tests substantiate the following statements:

Personnel will contaminate a clean room unless they are made to obey rigidly a set of strict regulations regarding masks, freshly sterilized clothing, and shoe wrapping. Regulations for cleaning for all other personnel must be identical to those imposed on members of the actual surgical team.

Proper filters can be installed and air pumps operated for delivery of any needed amount of bacteria-free air to a sterile room under positive pressure.

Unrestrained laughter and conversation and unrestricted movement about a room cause very rapid rise in bacterial content of the air in the room. Gauze masks worn during such activity delay the rate of rise of contamination somewhat, but, after 20 minutes, levels of air pollution are about equal to those in tests where no masks were worn. Pollution by respiratory exhalation can be stopped by suitable filter-type masks. Adequate masking alone will not prevent contamination of a room and its contained air.

Sterile clothing put on by personnel and then worn into contaminated areas will immediately become contaminated and will introduce contamination into a sterile room if worn back into it. The term "contaminated area" is applicable to any hospital area, such as corridor, ward, or room, which is not subject to special supervision. The practical solution to this problem lies in provision of quick-change clothing of a type that goes on and off without passage over the head or feet.

Shoes cannot be decontaminated by any practical means. Freshly autoclaved shoes worn into a public corridor and ward, and then into a sterile room, will introduce contamination into that room. Use of protective clean coverings of the entire shoes before the wearer is admitted to a sterile area is the only way yet found for eliminating contamination thereby.

Every article of furniture or equipment that enters a sterile room from elsewhere must be decontaminated first if the room is to remain sterile. This can be done by washing, autoclaving, or appropriate wiping with detergent or antiseptic solution for a sufficient length of time.

Blankets, as they are found on the bed of a patient and in use, are often heavily contaminated and will transfer infection from bed to bed or person to person if moved. Similarly, they will transfer infection when allowed to enter a sterile room if they are on a patient as a part of the covering brought with him. Blankets can be returned uniformly from the standard laundry process in a sterile condition, if subjected to treatment with the detergent-disinfectant in the final rinse of the laundry washing cycle.

Mattresses are probably subjected to less direct patient contact than are other similar items, i. e., blankets, sheets, or pillows. Generally speaking, the bulkiness of mattresses discourages personnel from making effective efforts to clean them. Repeated random cultures were taken from mattresses in constant use, and these cultures convincingly showed that they bear large numbers of bacteria. Brisk application of a detergent-disinfectant solution with a brush, and used in amounts insufficient to cause soaking of the mattress surfaces, was many times shown to be an adequate method for reduction of bacterial counts to very low levels. No issue is here raised as to the sterilizing properties of actinic rays, but it was not possible to show consistent bacterial reduction through prolonged exposure of mattresses to sunlight. The porous nature of mattress tickings offers sufficient protection for bacteria to reduce actinic radiation effectiveness. The study of how to clean mattresses clearly demonstrated the genuine benefits to be achieved by combining a bactericidal detergent agent with diligent manual intent.

Vacuum cleaners of any except the filtration type will contaminate a clean room. Those which blow air out at one end after having passed it through a cloth bag where the dirt presumably is caught carry the same or a larger number of bacteria out the back than are brought in through the front. Vacuum cleaners which use a filter retain particulate matter very effectively and are the only types which should be used in hospitals.

Although any surface or area whatever can be brought to a state of cleanliness or even sterility by sufficient mechanical cleansing and antiseptic solution application in combination, maintenance of cleanliness or sterility of the surface and of the area depends on the type and amount of usage, the frequency of rewashing by the techniques previously enumerated, and the amount of bacteria, dust, and fomite concentration in the area where the surface is located. If ventilation and type of usage remain the same in a room, bacterial contamination of air in that room can be significantly reduced by daily application of the techniques which have been described above. Three of the very effective ways of keeping low the chance of bacterial cross infection are the use of protected dressing carts, the wearing of gloves and masks by all personnel doing dressings, and the isolation of patients harboring any infection.

Cleanliness in Operating Rooms—Base Line

Critically analytical evaluation of the cleanliness of the operating rooms, according to standards which had been established by the tests outlined in the previous section, showed that they really were not so clean as had been thought. As soon as people began to work about the rooms there was too much dust in the air. The powder on gloves was one source, and a film of this powder was making a good culture medium as it settled into crevices in corners. The inside of light fixtures contained dust particles which were shaken into the air as the lights were moved about. The undersurface of tables, adjoining surfaces on cabinets, and many other places normally thought of as having been cleaned could be shown to have fingerprints of grease spots. Dust or dirt could be taken off the wheels of the cart that brought the patient from the ward to the operating table if one sought for the dirt with a wet cloth. Anesthesia equipment and suction machines yielded positive cultures.

The use of powder in the operating rooms was stopped. The entire pavilion was subjected to the ultimate noncompromising type of mechanical cleansing that had been proved effective elsewhere, and a supervisory program was established which maintains this status each day and every day. When this had been done it was found that there was, for the first time, a base line of reliability. From this basis, studies were made which were not only consistent with common sense but also free of the frustrating, erratic irregularity and unpredictability that was characterizing attempts to study other factors before this base line of absolute room cleanliness was established.

The exact origin of a wound infection often is difficult, if not impossible, to assign. Many observations have led to suspicion that most of the sporadic infections of clean wounds at Huggins Hospital have occurred in the operating room. They have been deep seated. They have been heralded by deep cellulitis with subsequent manifestations superficially, and they have been accompanied by systemic reactions. The appearance has been different from that of a superficial or stitch abscess, which subsequently shows signs of subcutaneous involvement. In fact, nine-tenths of the contaminations that cause wound infections are believed to arise in the operating pavilion area, from entry into the wound of germs from the air, or from fomites about the personnel and patients, including those of the patient's skin. The physical areas and the number of personnel involved, therefore, are small compared to the hospital space and employees for the hospital as a whole.

Cleanliness in Operating Rooms—Air

An efficient air conditioning system can readily be made to deliver dust-free and nearly sterile air into a room at a higher pressure than the atmosphere or adjacent areas by one of several effective ways. After testing of various methods, the type of air conditioning found to be best for Huggins Hospital operating pavilion was the use of filters alone.[4] Filtered air is delivered to each of two operating rooms through a central duct in the ceiling. It is removed in part by suction outlet ducts in side walls near the floor and at a height of 7 ft. and in part by a constant flow of air outward through the crevices around the doors and into an intermediate room lying between the two operating rooms. From this entryway or intermediate room, air again passes outward under positive pressure through another set of double doors to a short passageway. The passageway connects at either end with a dressing room and on the opposite side to a public corridor.

Air sampled as it entered the operating rooms through the ducts was repeatedly demonstrated to be sterile. There was a constant flow of air outward, even when the doors were opened, and yet sporadic instances of infection were appearing and these seemed to be originating during the course of the operative procedures. Furthermore, each of these rooms carries an ultraviolet light installation with demonstrable germicidal intensity of 90% killing power at 10 minutes, at a height of 8 ft. It was shown repeatedly, by sieve samplings on many occasions, that air delivered into the rooms as above described would remain sterile when the room was not in use. As soon as usage started, the bacterial counts would gradually rise to levels which were undesirable.

Practically speaking, infection or contamination of a clean room that is receiving only clean air into it is introduced by exhalations of personnel entering the room and by fomites from the clothing, shoes, or objects that people entering the room bring with them. Much study of the air filtration problem in reference to personnel has been done in the mining and fumigating industries.[5] In these industries the problem is largely one of protecting the personnel from the atmosphere or environment. They are concerned with taking fumes and particulate matter out of the air which is to be inhaled by the personnel.

The problem is reversed in surgery, and one is concerned mainly with protection of the atmosphere against germs exhaled by personnel in order that it may not be contaminated and transmit infection to the patient or his open wound. For many years, the traditional gauze mask has been worn in recognition of this problem and as one attempt at solution. Unfortunately, gauze masks are of negligible efficiency insofar as protection of room air against bacteria contamination is concerned. Doubling the masks and changing them at frequent intervals, such as once an hour, was tried with the thought that this might be a tolerable answer. There is a discernible barrier effect directly in front of a dry gauze mask and, more noticeably, in front of doubled dry gauze masks for short periods of time after they are put on. This protective effect diminishes rapidly as the mask becomes moist, is related to the amount of talking or forcefulness of breathing, and is down to less than 10% efficiency after 10 minutes if the wearer is also talking. However, there is a billowing-out effect around the sides of these masks from the beginning of wearing, no matter how carefully they are applied. With use of sieve sampler techniques one can gather large numbers of bacterial colonies from air emerging beneath the sides of these masks from the moment that they are put on.

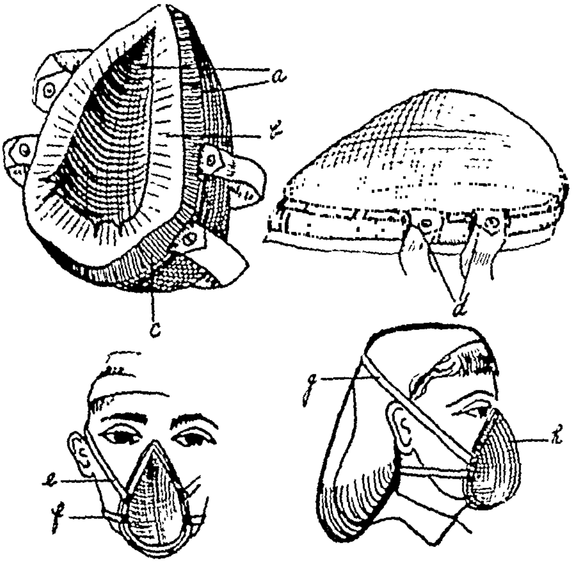

Fig. 1.—Fitted filter masks: *a*, inner and outer wire screening, *b*, adapter ring of autoclavable fiber foams, *c*, spring-constant adaptability to facial contours, *d*, snap-on elastic structural holders, *e*, elastic headband, *f*, detachable elastic band, g, best positions for wearing bands for holding mask, *h*, mask formed to maintain complete central vision.

Therefore, an extended study was made of the masking problem in search of an efficient answer that would also be a comfortable one for the wearer. A mask made as a common gauze mask and simply containing a filter instead of a piece of gauze is really little better than the gauze. It will stop the direct passage of bacteria through the mask, but the billowing out effect is unchanged. In fact, the situation can be made even worse than by a gauze mask if one chooses a completely impervious mask and substance to put in front of the nose and mouth. The spill-over effect is then aggravated. An essential feature of any filter mask that really makes tight and nonleaking contact with the skin of the wearer is that it have an exchange reservoir. Otherwise, the wearer will have a sense of suffocation and of partially obstructed air exchange both inwardly and outwardly. A mask which is doing its job effectively will also cause moisture accumulation within the reservoir, and some means of absorbing this moisture must be provided. An interchange surface must be available of such area and characteristics that air may pass through the filter with stoppage of bacteria, but at a rate which will provide adequate oxygen availability and carbon dioxide dispersal and, simultaneously, cause neither significant suction effect during inspiration nor positive pressure effect during expiration. The mask must be light and comfortable. It must be of high efficiency at the end of many hours of use. It must be cheap enough to throw away or be completely sterilizable and easily maintained.

After testing a dozen ideas which had to be discarded and over a score of models which proved not to be good enough for one reason or another, a filter type of mask (fig. 1 and 2) was finally developed and produced which meets in practice the stringent criteria set in the preceding paragraph. Demonstrations of almost total efficiency have been accumulated on a group of different personnel, tested for periods in excess of five hours. As an outcome of the numerous tests of this type of properly fitted filter mask, it may be stated that air contamination of a room by human exhalation is at least 98% preventable and controllable by proper masking of all persons entering the room. Such masks are now available, usable, and proved in practice.

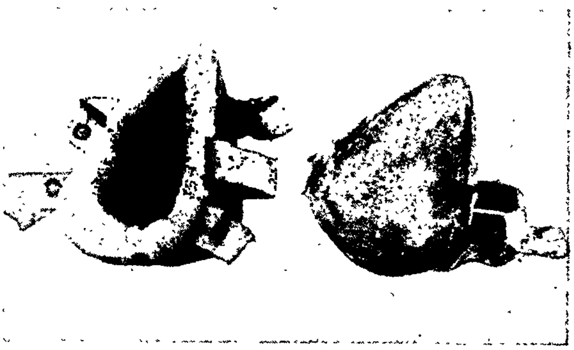

Fig. 2.—Fitted filter mask.

The patient is masked, just as are members of the operating team. Anyone entering an operating room, at any time and for any reason, should be properly masked before entering and should wear the mask during his entire stay there. This statement applies to the clean-up period after operation, insofar as trained personnel is concerned. It applies also to cleaning and maintenance help. No exceptions to wearing of proper masks should be permitted.

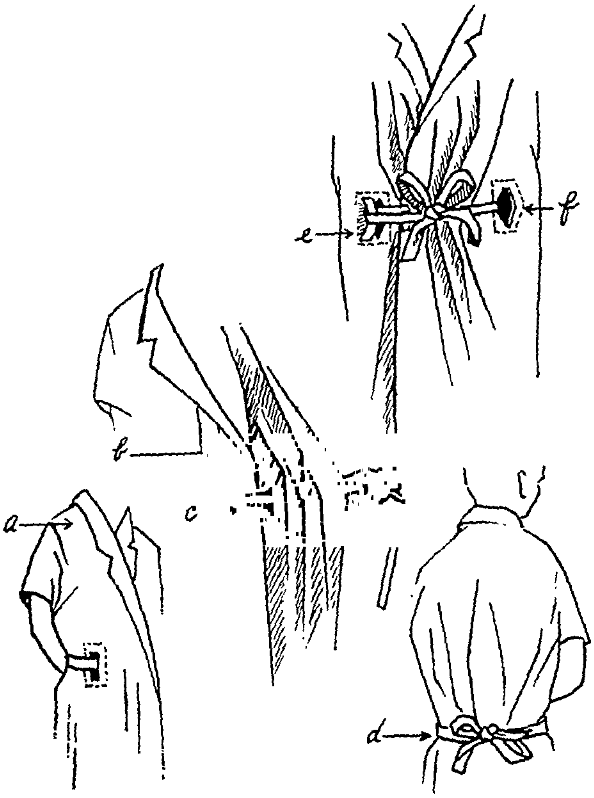

Fig. 3.—Wrap-around, quickly changed gown: *a*, reversible collar, *b*, double-breasted front coverage, *c*, pass-through opening for tie cord, *d*, tie in back, *e*, strap for front tying, *f*, pass-through opening for reverse position.

Air contamination was drastically reduced after adoption of this type of mask and insistence on its constant use by all persons entering the operating room, as shown by the following data: On July 18, cultures from operating room suite 1 showed a sieve sampler count of eight colonies on a plate, three of which were weakly hemolytic. This was the status after the room had been made ready for use during the day. Cultures from operating room suite 2 showed 23 colonies per plate after one hour of use. In the entryway leading to the operating rooms, a count of 17 colonies per plate was found. In the nurses' dressing room on the same morning, the count was 53 colonies on a Petri plate. On July 22, efficient filter masks were worn and cultures from suite 1 showed six colonies and those from suite 2 showed three colonies per plate after an hour of use. The entryway to the operating rooms showed nine colonies. The doctors' dressing room showed 55 colonies. In other words, there was a noticeably good effect from the adoption of efficient filter masks, but a condition of full sterility was still further from attainment than seemed desirable and possible.

Cleanliness in Operating Rooms—Clothing

A more careful scrutiny was therefore made of clothing. A freshly autoclaved gown was put on and worn for the five minutes required to change a dressing on a patient known to have an infection with Proteus organisms. Care was taken not to touch the gown with the gloved hands, and reasonable care was exercised in protecting the gown from contact with the bed, in the same manner as when changing a dressing while wearing street clothes or operating room clothes. Cultures taken immediately afterward from this gown yielded Proteus organisms. Culture was taken from a clean operating room uniform and subsequently showed no growth. The uniform was then put on and worn for 45 minutes in the course of routine early morning rounds (presumably clean), before scrub-up for the first operation. No dressings were taken down. The hands were washed each time after a patient had been examined. The clothing was known to have come in contact with several beds, but only in the manner that is normal in the making of rounds. At the end of rounds, the uniform was taken off and cultures taken. These showed contamination of the uniform by a wide variety of mixed organisms. Additional tests of a similar nature were carried out on subsequent days.

Proof was accumulated that all clothing worn in a nonclean room, for however brief a time, is almost surely contaminated by fomites and that such clothing will introduce contamination into a clean room if worn into that room. For example, a clean nurse's gown was put on and worn for the two minutes required for the nurse to leave the operating pavilion, cross a public hallway, and enter a recovery room for delivery of a flask of solution. She returned immediately to the operating pavilion and the scrub gown was shown by culture to be contaminated by a mixture of bacteria. The bottoms of men's trousers are among the worst sources of bacterial spread in this manner. Not only are they likely to be soiled by passage over filthy shoes, but they flap with walking and their nearness to shoes, the floor, and the dust usually present on a floor makes them an infection hazard. After starting these tests, we rapidly realized that the frequent trips in and out of an operating pavilion for doing of chores and errands, as is so common a practice and need with physicians and nurses, is hazardous from the standpoint of contaminating an operating room.

Thereafter, a long series of studies was done with respect to how the obvious inconvenience of the necessary change of clothing might be overcome in order to be wearing freshly sterilized clothing on each entry or reentry of the operating room and to fulfill the strict requirements of operating room area protection. This element of protection is essential in respect to clothing worn by personnel of all types, whether senior surgeon, intern, pavilion supervisor, scrub nurse, anesthetist, instrument maid, cleaning man, or anyone else, without exception. We sought to devise clothing that would permit quick change with little loss of time and scarcely any risk of contamination in the process of changing. Such a garment should be quickly resterilizable, reasonably good-looking, and comfortably acceptable to those who would need to wear it. After a succession of 18 trials and models, a sexless, sizeless, sideless, quick-change, double-breasted gown was developed that seems to meet the above requirements satisfactorily (fig. 3 and 4). One garment can be taken off and a new one put on within 30 seconds. It provides protection against exposure, ties in the back, and has no need to be turned in respect to sleeves, as both sides are identical. It will overlap in either direction in recognition of the different habits of men and women in putting on garments, and it is given rough-dry laundering to save ironing expense. This is the only practical garment yet found for wear in clean rooms where frequent exit and reentry are necessary. A freshly sterilized gown of this type is put on for each reentry of an operating room.

Cleanliness in Operating Rooms—Shoes

Shoes are an article of clothing, and all statements previously made about clothing in general are applicable to shoes in particular. Additionally, shoes present surfaces and are specifically subject to the rules for attaining cleanliness outlined in the early part of this paper in respect to the cleaning of rooms and the furniture within rooms. By nature of their function, shoes are always dirty, from a bacteriological standpoint, and 10 minutes' time spent in mechanical scrubbing with a good disinfectant-detergent is the only method discovered that will suitably clean them. This fact makes decontamination of shoes, before reentry to a clean room in active use, impractical and impossible of attainment.

A shoe that was cultured without having any treatment at all showed a massive growth of a mixed flora of bacteria. A second shoe that was soaked in a 10% phenol detergent solution for one minute showed a relatively high number of bacteria growing out from a swab passed over the sole. The same was true of another shoe that had been treated with pure phenol. When shoes that had been soaked for one minute in each of these strengths of solutions were scrubbed vigorously with a brush for 30 seconds, the number of viable organisms remaining dropped off markedly. However, 10 minutes of vigorous mechanical scrubbing was necessary in order to render a previously dirty shoe surface sterile to culture. It is of interest to note that the antiseptic detergent solutions were fully active in their bactericidal effect, insofar as they were able to come into direct contact with organisms present. Where there is some protective effect afforded through the presence of a layer of dirt, this bactericidal action is inhibited and organisms are readily grown on culture mediums. It is now apparent that, in order to have an effective shoe-soaking arrangement, one would need to set up a brush or series of brushes over which the shoe could be scrubbed while being wetted with an antiseptic solution and that one would need to carry out this activity for 10 minutes if he expected to produce a sterile shoe surface. There is nothing really surprising in the finding, except that anyone should ever have thought that simply wiping

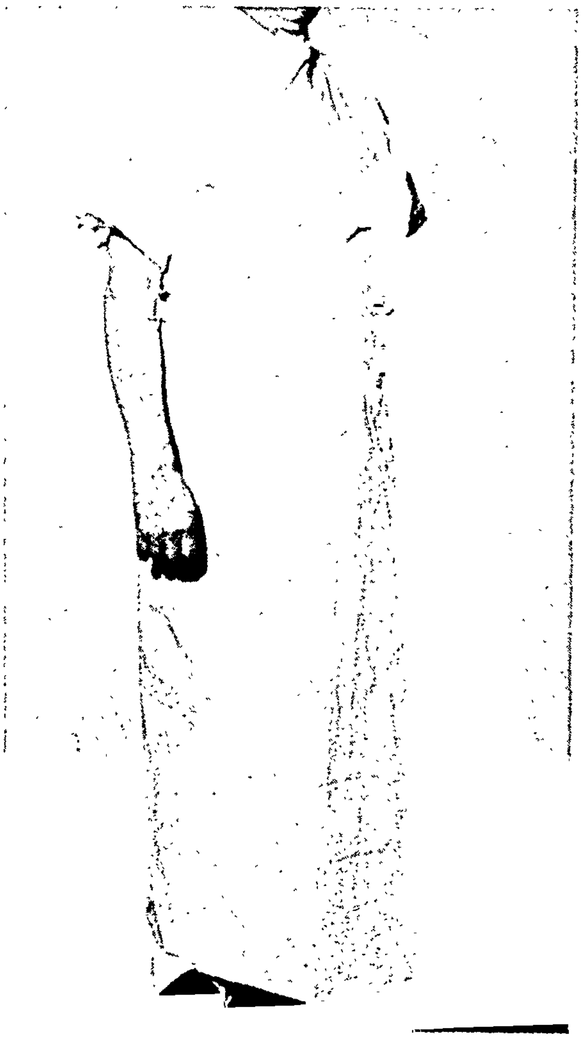

Fig. 4.—Wrap-around, quickly changed gown.

ordinary shoes with a detergent cloth would decontaminate them. No one should believe, any longer, that a surgeon's hands can be sterilized by dipping them in a detergent solution or even by washing them for a minute or two with some such solution. Every serious student of the subject knows that a good, enthusiastically applied, 10-minute mechanical scrubbing is necessary to clean a surgeon's hands. Why should it be supposed that his shoes would require much less?

This intensive study of the problem of protecting the operating suite against contamination from shoes worn by personnel yielded reaffirmation of the axiom that mechanical energy must be expended on the surface of whatever is to be cleaned.

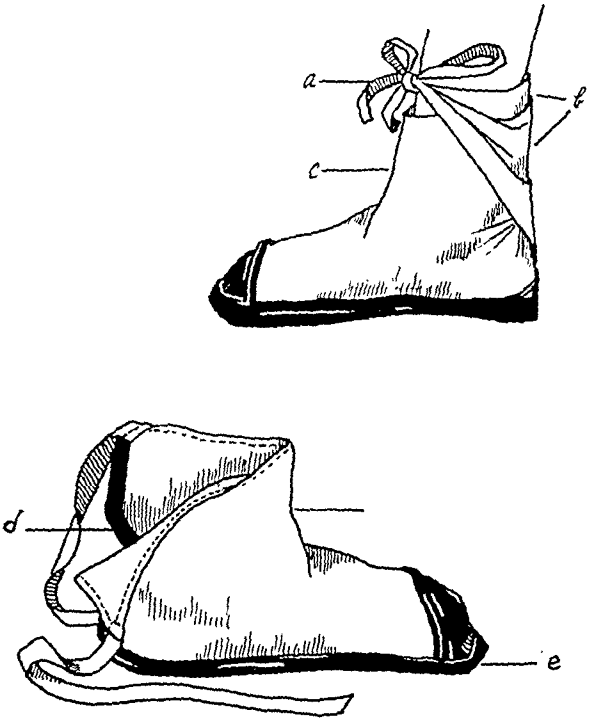

Fig. 5.—Conductive, protective bootie: *a*, front tie, *b*, wrap-around for complete coverage, *c*, weight to cover both shoe and sock, *d*, rubber strap conductor coming to skin contact, *e*, conductive rubber soles.

Phenolated detergents, chlorinating compounds, iodine, benzalkonium chloride, in whatever strength of tincture, formulation, or solution, all are ineffective unless combined with mechanical effort.

Attention was turned to other methods. After extensive testing and modeling, a washable, flexible, slip-on, wrap-around, cloth-top, conductive rubber-soled bootie was developed and produced that meets all requirements (fig. 5 and 6). It is worn by everyone while they are in the operating rooms or adjacent rooms. They may be worn outside of the operating pavilion at will but must be discarded and a freshly cleaned pair put on before reentry is permitted. They may be worn out of the operating rooms and into the dressing rooms only without being changed before reentry. This is a satisfactory compromise with practicality, in that the soles of the booties are readily cleansed by wiping them on a blanket soaked in detergent antiseptic solution after such brief exposure to a relatively clean area.

Comment

What was true in other areas is true in this: 1. An operating pavilion can be cleaned up by mechanical effort, application of detergents and antiseptic solutions, and persistent attention to details of care. 2. An area so cleaned will remain clean until contamination is introduced into it. 3. Personnel can so conduct themselves in respect to the masks, clothing, and shoes worn that they need not introduce infection to a room by virtue of their presence in the room. 4. The air introduced into a room through the conditioning system can be delivered sterile or nearly so. 5. All inanimate objects taken into a room can be delivered there in clean or sterile form. In other words, the problem of maintaining sterility, or conditions so nearly sterile that they can be regarded as totally clean, is a soluble one in respect to a given room. The solution can be kept within economically practical bounds for a relatively small area, such as an operating pavilion, because of the geographical confinement and because of the high level of intelligence, understanding of need for cleanliness, and dedication that characterizes the attitudes of most persons who work about operating pavilions.

The following absolutes of sanitation must prevail and are the criteria for attaining and maintaining a bacteria-free operating room. There is an inner zone, the operating room itself, where uncompromisingly rigid and total requirements of sanitation are constantly in effect. Every item admitted to this environment must be as nearly germ free as it is possible to make it. An interchange area exists inside which all aseptic criteria are fulfilled: the shoes are wrapped in booties, the clothing is clean, and a filter mask is worn. The interchange area itself, where these conditions are established on passing inward, contains the scrub-up sink. Impervious aprons are required during scrub-up to prevent wetting of the clothing with droplets from scrub brushes.

A zone lies outside of the interchange area where complete cleanliness in reference to the room and floor and furniture is maintained. But here masks are not worn. Booties may or may not be on. Pavilion clothing may be worn or not. These areas are the dressing rooms and the entryways to these rooms and to the interchange zone. They lie outside the interchange zone but within the operating room pavilion.

Outside of the pavilion is the rest of the hospital. From the standpoint of protection against germs, the area outside the pavilion is outside the pale and includes everything and everybody.

On the floor of the interchange area there is a blanket 6 ft. wide extending from wall to wall; this is put down freshly washed each day and is soaked in a disinfectant detergent solution. When a transfer cart brings a patient to this zone, the cart is stopped on the blanket and the patient is transferred to the operating room cart. If a recovery room cart is taken into the operating room itself, the cart is first washed with antiseptic solution, including the wheels and tires. The clothing and covering which the patient is to wear in the operating room are put on him in the interchange area.

Personnel put on their masks in the interchange area or outside it. They put on their booties from the sterile supply while sitting on stools on the detergent–antiseptic–soaked blanket in the interchange area, so that the booties present over-all sterile surfaces from the time the protected area is entered. If a person must leave the protected area temporarily to go into a dressing room, the gown may be worn back into the protected area, as may also the booties if their soles are wiped off on the wetted blanket. This is germicidally effective because there is little dirt or dust in the air or on the floors of the dressing room or operating pavilion. The booties have been washed and are always thoroughly clean prior to the current wearing, and the soles are therefore readily cleansed to meet practical requirements.

Although such conditions can be sought and temporarily achieved in other departments of the hospital, such as wards, kitchen, bathrooms, laundry, and examination rooms, one must concede that there are not enough people with requisite supervisory skill or dedication to work for fulfillment of these requirements beyond a limited zone. There is a difference between what can be proved and what can be done, unless one is able to provide total, constant supervision. Fortunately, the area of a hospital in which such exacting standards of performance must be met is the same one where they can be maintained in ways that are practical, economical, and reasonable.

A concept of this whole problem of operating room protection is as follows: There is a certain area, which is the operating room itself, where ideal performance is a minimum requirement. There is an outer area, the public area, where contamination is universal and controllable only within limits. Between these extremes, there must be degrees of sterility which increase as one moves inward but where some leeway in the intermediate zone is necessary.

The practical effect of willingness and ability to carry out this program on a daily basis is shown by the following reports on cultures taken by a bacteriologist, without prior announcement to anyone that he had plans to take them and at the end of a period of time in which two operating rooms, the entryways, the interchange zone, and the dressing rooms and associated passageways had been steadily in use for four hours. Five-minute air samples were taken by a sieve sampler technique. Operating room 1 showed two colonies. Operating room 2 showed one colony. The scrub room or separation room between the two operating rooms showed 14 colonies. Eleven colonies were obtained in the hallway between the dressing rooms and 20 colonies in the nurses' dressing room. At the same hour, for purposes of comparison, culture samples were taken from a public hallway outside the operating pavilion, and this showed 49 colonies, 15 of which were potently hemolytic and 2 of which were soil organisms. A plate exposed in the men's ward showed the presence of 61 colonies, of which 12 were hemolytic, 6 were potent hemolizers, and 1 was a soil organism.

Fig. 6.—Conductive, protective bootie.

The skin of a patient can be cleansed in the same manner as can the skin on the hands of a member of the operating team. Nothing less than a 10-minute, enthusiastically applied, mechanical washing with detergent soap solution and water, followed by a process of drying and application of antiseptic solution, will suffice. The proposition that skin on the hands of personnel should be covered by thin, sterile, impervious material, such as rubber or plastic gloves, has been accepted and universally applied for three generations. The skin of the patient has not been similarly treated and has remained a source of risk to wounds, even though precautions to cover skin margins and subcutaneous tissues, and other protective measures, were taken.

Recently, a thin, transparent, autoclavable, plastic film material (Vi-Drape surgical film) has become commercially available. It is capable of being made adherent to the skin by the application of a spray-on adhesive bond (Vi-Hesive surgical adherent).

The adhesive bond is first sprayed on slowly at a distance of 10-12 in. over the whole scrubbed area and allowed to dry for 30 to 45 seconds, until tacky to touch. The sterile film is then held over the area, lowered first over the areas of intended incision, and then molded onto the skin over the whole operative site. The usual surgical drape is then applied.

This technique has become an integral part of the draping and preparatory procedures to further isolate the wound from its environment prior to making the skin incision, which is made through the plastic material. The latter remains intimately adherent to the skin margins, and the skin, although visible, is completely occluded from the operative area for the duration of the procedure. The adhesive bond lasts for at least many hours, and protection against contamination of the operative area from the skin can be maintained indefinitely by the sterile impervious plastic membrane.

These materials have now been used in over 300 surgical cases. They are in no sense a substitute for scrupulous and meticulous skin preparation but are an added protection of the patient's skin, equal to that afforded by gloves on the hands of operating personnel.

Summary and Conclusions

Extensive studies of sources of infections in hospitals led to recognition of the following fundamental facts: Frequently repeated, intelligently applied, mechanical effort in combination with a good disinfectant-detergent will clean any area. Maintenance of cleanliness or sterility of the surface depends on the type and amount of usage, the frequency of rewashing by these techniques, and the amount of bacteria, dust, and fomite contamination.

If ventilation and type of usage remain the same, bacterial contamination of air in a room can be significantly reduced by daily application of proper cleaning techniques. An efficient air conditioning system can readily be made to deliver dust-free, nearly sterile air into a room under positive pressure. Such air, delivered into a clean room, will remain nearly sterile indefinitely, unless contaminated by introduction of infection. This is introduced by exhalations of personnel entering the room and by fomites from clothing, shoes, or objects brought in.

Air contamination of a room by human exhalation is at least 98% preventable and controllable by proper filter masking of all people entering the room.

All clothing worn in a nonclean room, for however brief a time, is almost surely contaminated and will introduce contamination into a clean room. Because of problems of time consumed, inertia, and contamination from passage over unclean areas of trousers or slip-on garments, double-breasted, wrap-around, quick-change, lace-tying gowns are the only practical answer yet found for wear in clean rooms where frequent exit and reentry are necessary. A freshly sterilized garment of this type must be used for each reentry of a clean room. If used where there are flammable gases, the garment must be constructed of a material which will not produce static electricity. All statements made about clothing are applicable to shoes. Quickly donned, temporary shoe coverings are a practical solution to attainment of clean footing for all personnel using a clean room. Fresh coverings must be used each time a clean area is to be entered. If flammable gases are used in the clean room, the shoe coverings must have conductive soles as an integral part of their construction, and these soles, as well as the tops of the coverings, must be sterilizable by autoclaving. Critically competent supervision and working personnel with attitudes of dedication to maintenance of cleanliness are necessary.

Nine-tenths of the causes of wound infections are believed to arise in the operating pavilion area from entry into the wound of germs from the air or from fomites about the personnel and patient, including those of the patient's skin. The geographical area and the number of personnel involved, therefore, are small compared to the hospital space and employees for the hospital as a whole. A sterile skin surface can be achieved by 10 minutes of diligent scrubbing with germicidal detergent soap and water. The sterility of this surface can be maintained indefinitely by the proper application of an adherent transparent plastic film.

A room which looks clean, smells clean, and feels clean is most likely to be clean and to be proved clean also when subjected to critical testing for bacterial and particulate matter content. For nine-tenths of the hospital, a good housekeeper with an eye for dirt and an ability to get it removed is a better investment than complicated bacteriological testing equipment and routines. For the other one-tenth of the hospital area, meaning essentially the operating pavilion and the nursery, standards, controls, and fulfillment must be of the ultimate type from which no appeal for leniency is tolerable.

The detergent-disinfectant uesd in this study was supplied as Tergisyl and the *o*-phenylphenol—*p*-tertiary amylphenol as Amphyl by the Lehn & Fink Products Corporation, Bloomfield, N. J. The plastic surgical film material was supplied as Vi-Drape surgical film and the spray-on adhesive bond as Vi-Hesive surgical adherent by the Aeroplast Corporation, Dayton, Ohio.

EXPERIMENTAL PANCREATITIS–RECENT CONTRIBUTIONS

Morton I. Grossman, M.D., Ph.D., Los Angeles

The fact that pancreatitis and disease of the biliary tract frequently occur together has led to many types of experiment on possible interactions between bile and pancreatic juice. Especially tempting is the hypothesis that some constituent in bile, in tissue juices, or in inflammatory exudates is capable of activating pancreatic juice and so causing the familiar picture of hemorrhagic necrosis of the pancreas. There is also a tendency to assume that the appearance of abnormal enzymes in the circulation during pancreatitis means that they were produced in the pancreas and are responsible for the symptoms of shock. In reality, the injurious factor in pancreatitis has not yet been identified, and the role played by circulating proteases remains to be explained.

Many methods for producing experimental pancreatitis are available, and descriptions of new methods are constantly appearing. All forms of experimental pancreatitis bear some resemblance, in gross and microscopic pathology, to certain forms of the human disease. This resemblance is best interpreted as indicating that the reaction of the pancreas to injury is rather stereotyped, differences in the pathological picture being due more to the rate and amount of injury than to the nature of the injurious agent. For this reason, caution must be used in arguing from experimental pancreatitis to the pathogenesis of the human disease.

Several recent reviews systematically survey the literature on experimental pancreatitis.[1] This paper will not attempt to duplicate these efforts but will deal only with selected topics which invite evaluation in the light of recently acquired evidence.

The Bile Factor

The frequent association between disease of the biliary tract and pancreatitis is a well-documented clinical fact. Of the various theories which attempt to explain this association, that of Opie, postulating reflux of bile into the pancreatic duct through a common channel, is dominant in terms of the number of adherents it commands. That a communication frequently exists between the common bile duct and the major pancreatic duct of human subjects has been clearly established on the basis of both anatomic dissections and operative and T-tube cholangiography. However, the question of whether bile actually refluxes through this communication under physiological or pathophysiological conditions has not yet been unequivocally answered. The pressures used during direct cholangiography are artificially high and do nothing more than demonstrate that the communication exists. The availability of intravenous cholangiography offers the opportunity of detecting biliary-pancreatic reflux under conditions of spontaneously occurring pressure. To my knowledge, no one has yet demonstrated biliary-pancreatic reflux by intravenous cholangiography in normal subjects or in patients with pancreatitis, with or without administration of opiates. A careful search for this phenomenon should be made.

Assuming that reflux of bile into the pancreatic ducts can occur, will it cause pancreatitis? Critical evaluation of the enormous literature on this subject leads to the conclusion that pancreatitis results from injection of bile into the pancreatic ducts only when the pressures used are great enough to cause mechanical rupture of the acini. It is unlikely that pressures of the magnitude required ever occur under physiological conditions.

New light on the possible role of bile in the pathogenesis of pancreatitis comes from the studies of Elliott and co-workers.[2] These investigators have

Read in the Symposium on Pancreatitis before the Section on Gastroenterology and Proctology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

confirmed the findings in earlier studies by showing that, when gallbladder bile was allowed to flow into the pancreatic duct under relatively low pressure (40 cm. H_2O), little entered the gland and no significant damage resulted. However, if the bile was incubated with pancreatic juice of high enzyme content or with trypsin for 12 hours before allowing it to flow into the pancreatic duct, then large amounts entered (18 to 30 ml. in one-half hour) and lethal hemorrhagic necrosis ensued. Presumably, the proteolytic enzymes of pancreatic juice degrade a substance in bile (perhaps mucoprotein) which modifies the ability of bile to penetrate and injure the pancreas. As early as 1906, Flexner[3] showed that the injurious agent in bile is bile acid and that it is more effective in producing pancreatic damage when freed of the protein of bile. Whether such an interaction of bile and pancreatic juice can occur in the intact organism remains problematic.

Pressures in the Pancreatic and Biliary Ducts

Most of the earlier studies on pressures in the pancreatic and biliary ducts were concerned with so-called secretory pressures, that is, the vertical height to which fluid would rise in a tube connected to a cannula occluding the duct. Menguy and associates[4] have recently devised a method for making serial pressure measurements in the physiologically intact pancreatic and biliary ducts of unanesthetized dogs over periods of many months. These studies have shown that, even during fasting, remarkably high pressures are present, the mean value for the pancreatic duct being 14 cm. H_2O and for the biliary duct 7 cm. Stimulation of the flow of juices in these ducts by meals or by injection of secretin or dehydrocholic acid usually, but by no means always, caused a modest increase in pressure.

Since large increases in flow rate can occur with little or no increase in pressure, it is valid to deduce that resistance to flow is subject to marked physiological adjustment. Conversely, it has been clearly demonstrated that when outflow resistance is increased no decrease in rate of flow occurs until the outflow resistance approaches the level which will produce complete cessation of flow.[5] Thus, unlike a water tap in which flow is inversely proportional to outflow resistance, the pancreatic gland is capable of increasing intraductal pressure in response to increased outflow resistance so as to maintain flow constant. Whether the increased intraductal pressure which results from partial obstruction to outflow can be sustained for long periods of time and, if so, whether it would lead to damage to the gland has not yet been studied.

Of special interest in the studies of Menguy and associates was the demonstration that introduction of alcohol into the duodenum caused a sustained rise in pressure in the pancreatic duct. The association between acute and chronic alcoholism and pancreatitis is evident clinically, and information about the physiological effects of alcohol on the pancreas is, therefore, important.

Vascular Factors

The recent studies of Thal and co-workers[6] have convincingly reasserted the effectiveness of ischemia in producing fulminant lethal hemorrhagic pancreatitis. When the capillaries and venules of the pancreas were made to undergo thrombosis by the local Shwartzman or Arthus phenomenon or were severely constricted by introduction of staphylococcic toxin through the duct, typical diffuse hemorrhagic necrosis rapidly ensued.

By contrast, it has once again been demonstrated, in the studies of Menguy and associates,[7] that ligation of the major arteries and veins of the pancreas produced only small patches of necrosis, although when such ligation was combined with obstruction of the ducts the severity of injury was increased. The severe hemorrhagic pancreatitis which Pfeffer and co-workers[8] produced by creating a closed loop obstruction of the portion of the duodenum where the pancreatic ducts enter is another example of the cooperation of obstructive and ischemic factors.

Two principles emerge. First, because of the richness of the collateral blood supply to the pancreas, ischemia of the tissue sufficiently severe to produce necrosis, when acting alone, can only be achieved by stopping the flow of blood in the smallest vessels. Second, lesser degrees of ischemia can greatly enhance the damaging effect of other factors such as obstruction of the duct.

Pancreatic Proteases and Lesions of Pancreatitis

It has long been assumed that the proteolytic enzymes of pancreatic tissue and of pancreatic juice play an important role in producing the lesions of pancreatitis. It is well established that both trypsin and chymotrypsin, when present in sufficiently high concentration, are capable of producing severe tissue damage at the site of their local injection. A prominent feature of this damage is necrosis of the walls of vessels and associated tissue hemorrhage. The hemorrhage with vascular necrosis seen in pancreatitis is comparable to that produced by injection of the pure enzymes, and this similarity is, to date, the strongest evidence available implicating these enzymes in the pathogenesis of the disease.

When trypsin or chymotrypsin is injected intravenously in a sufficiently large amount, death associated with shock occurs. The pathogenesis of this effect is uncertain, although there is evidence to suggest that it is due to release of vasoactive substances, such as histamine. Similarly, the damaging action of proteolytic enzymes injected into tissues may be dependent on local release of vasoactive substances which lead to ischemia.[9] It is often assumed that the shock which sometimes occurs in patients with pancreatitis is due to release of active proteases into the blood stream. Although many attempts have been made to demonstrate active pancreatic protease in the blood in both experimental and clinical pancreatitis, no convincing evidence for their presence has been adduced. Blood plasma has powerful antitryptic and antichymotryptic activity, and the amount of enzyme present in the blood must be great enough to overcome this inhibition before it can be measured.

Several groups of investigators have demonstrated a circulating protease in experimentally induced pancreatitis,[10] but it has not been proved that this protease is actually of pancreatic origin. Blood contains a proteolytic enzyme, plasmin, present mainly as an inactive precursor, plasminogen, and the blood concentration of both the precursor and the enzyme rise after a wide variety of nonspecific stresses, such as surgical operation.[11] Plasminogen may be converted to plasmin by a kinase of bacterial origin, streptokinase, which is incapable of activating pancreatic proteases. It has recently been demonstrated that there is elevation of the concentration of plasminogen as well as of an active protease with the properties of plasmin in animals with experimentally induced pancreatitis.[12]

In addition to their hydrolytic action on peptide bonds, pancreatic proteases have been shown to be capable of hydrolyzing a variety of amino acid esters and amides. The possibility of using these synthetic substances for detecting pancreatic proteases in the blood of patients with pancreatitis is receiving attention currently. Because blood plasma inhibits the esterase action of trypsin and chymotrypsin less than their protease action, it is possible to detect these enzymes by esterase measurements in the blood of animals after intravenous injection of amounts which produce neither shock nor death.[13] These methods offer great promise for elucidation of the pathogenesis of the experimentally produced and the clinical disease. However, these synthetic substrates are attacked by enzymes other than those of pancreatic origin. For example, arginine esters and arginine amides are split by trypsin, but they are also attacked by plasmin, thrombin, and tissue cathepsins.[14] In order to prove that elevation of the rate of splitting of such a substrate is due to pancreatic protease, it will be necessary to employ a variety of criteria, such as relative rate of splitting of different substrates and pH optimums. The recent report that patients with pancreatitis show an increase in the blood level of an enzyme which hydrolyzes benzoyl arginine amide[15] must be viewed in this light.

The proteolytic enzymes of the pancreas, trypsin and chymotrypsin, are secreted into the pancreatic juice in the form of inactive precursors, trypsinogen and chymotrypsinogen. An enzyme secreted by the intestinal mucosa, enterokinase, converts trypsinogen to trypsin. Once this process has begun, it proceeds rapidly because it is autocatalytic in nature, that is, trypsin catalyzes the conversion of trypsinogen to trypsin. In addition, the transformation of chymotrypsinogen to chymotrypsin is accomplished by trypsin, and this reaction is not autocatalytic.

In the literature on the pathogenesis of pancreatitis, one frequently encounters the statement that the conversion of pancreatic proteases from their inactive precursor forms to the active enzymes can be accomplished by a variety of agents other than enterokinase, including bile, tissue juices, and inflammatory exudates. It is thus assumed that if these enzyme precursors find their way into intercellular sites they will rapidly become activated.

This problem has recently been studied in detail. Pancreatic juice was collected from the ducts of unanesthetized rats and dogs with food acting as the stimulus for secretion. It was found that these juices invariably contained a trace of active protease but that this usually represented less than 1% of the potential proteolytic activity which could be released by activation with enterokinase. When tested on synthetic substrates which are attacked by trypsin, this spontaneously appearing active protease did not produce any hydrolysis. Another indication that this spontaneously active protease was not trypsin was the fact that when minute amounts of crystalline trypsin, equivalent in proteolytic activity to the spontaneously appearing protease, were added to the juice full activation, as great as with enterokinase, occurred within a few minutes.

A variety of substances were added to pancreatic juice to test their ability to produce activation of protease. Rat hepatic bile, dog gallbladder bile, 2% solution of sodium cholate, inflammatory exudate produced by injection of turpentine into the thoracic cavity of rats, an aqueous extract of human leukocytes, plasmin, thrombin, and streptokinase were tested. None of these substances, with the exception of thrombin, produced any increase in the rate of appearance of active protease over that seen with pancreatic juice alone during periods of observation up to 24 hours. The weak activating action of the thrombin preparation could be fully accounted for by its content of calcium. Calcium salts in a concentration of 0.05 M caused complete activation of pancreatic protease. The activation by calcium salts, which had been extensively studied by a number of earlier workers, is characterized by a long lag phase, during which only slight acceleration of activation occurs, followed by very rapid, presumably autocatalytic, total activation.

Unactivated pancreatic juice was injected into the thoracic or abdominal cavity of rats, and samples of it were periodically removed for assay of proteolytic activity. The increase in concentration of active protease over a six-hour period was slower than that of a similar solution incubated in vitro at 37 C.

These results offer no support for the view that tissue juices, bile, or inflammatory exudates are capable of activating pancreatic protease. The important problem of whether pancreatic proteases become activated during the course of clinical or experimental pancreatitis and, if so, how this is brought about, awaits a definitive answer.

Conclusions

The experimentalist could easily be beguiled into thinking that he knows a great deal about the etiology of clinical pancreatitis because he can so easily mimic the disease in animals. Actually, what is known is that there are a number of factors which can cause injury to the pancreas and that when this gland is injured it reacts in certain characteristic ways. The identification of the injurious factor or factors in the clinical disease has not yet been accomplished.

The experimentalist can be equally naive in regard to the pathogenesis of the disease. It is plausible and useful to hypothesize that injury to pancreatic acinar cells causes release of enzymes into tissue spaces and that these enzymes then produce characteristic types of damage and reaction. While this hypothesis is almost certainly valid in a general sense, its intimate details are but poorly understood.

NEW WORLDS AWAIT SENIOR CITIZENS.—From the accent on youth the time has come to recognize and develop the concept of maturity. From being sickness-oriented there is need for becoming positive-health-minded. From emphasis on chronological age the more accurate estimate of an individual is his biological or fitness performance capacity. From limiting the medical focus to the requirements of the individual there is a broader aspect, the family and the impact of disease on its group vitality. Acute diseases are now relatively less important than long term disorders and the necessity for their prompt control. Finally, the barriers of age retirement must be re-examined, and thought now should be directed to the second career. Family values, happiness and security, are rooted in the vitality, health and unity of each member. The healthier each one is, the healthier the family. A kind of crisis now exists in too many families where the older members are devaluated. No one can help the elder as much as he can help himself. A whole new world awaits the senior citizen who will become alert to his potentials.—E. L. Bortz, M.D., The Emerging Twentieth Century Family, INA Conference on Family Security, Disneyland, Calif., Jan. 9-12, 1959.

MEDICAL ASPECTS OF PANCREATITIS

Thomas E. Machella, M.D., Philadelphia

The diagnosis of acute pancreatitis usually depends on the finding of a high serum amylase level in a patient with acute severe epigastric pain, abdominal tenderness, vomiting, fever, tachycardia, and leukocytosis. Increasingly exact methods of diagnosis have led to increasingly conservative methods of treatment. Therapy includes continuous aspiration of gastric contents, parenteral administration of solutions to preserve the water-electrolyte balance and combat shock, and use of antibiotics. The treatment must be adapted to the case, and surgery may be necessary. Chronic pancreatitis is usually seen in older patients after repeated attacks of acute pancreatitis, or during the progress of tuberculosis, syphilis, or hemochromatosis. Laboratory studies of the blood, especially determinations of pancreatic enzyme levels and glucose tolerance, are important in diagnosis. Chronic pancreatitis leads to diabetes, steatorrhea, and calcification, with the possibility of sudden fatal complications. Treatment is designed to eliminate, if possible, the cause of recurrences and to compensate, by means of insulin, pancreatin, and diet, for the loss of the internal and external secretions of the pancreas.

The purpose of this presentation is to discuss the medical aspects of pancreatitis. Descriptions will be given of precipitating or etiological factors, clinical manifestations, laboratory findings, diagnosis, complications, and treatment of the acute and chronic varieties of the disease.

Acute Disease—Etiology

Acute pancreatitis consists of an acute inflammation of the pancreas, the clinical manifestations of which vary with the severity of the inflammatory process as well as the extent to which the exocrine and endocrine functions of the gland are deranged. The three main varieties, edematous, hemorrhagic, and suppurative, probably represent different degrees of severity of the same process. The disease occurs in both sexes and in many instances appears to be precipitated by the ingestion of a meal, an overindulgence in alcohol, or an emotional storm. Although it is encountered most frequently in middle and late adult life, at least 40 cases have been reported in children.

All cases of acute pancreatitis do not have a common etiology. A variety of factors have been held responsible. They include obstruction of the ampulla of Vater with reflux of bile into the pancreatic duct—the "common channel theory"; obstruction of the pancreatic ducts; alcohol, ethyl and methyl; metabolic disturbances—hyperlipemia, diabetes mellitus, malnutrition, pregnancy, isoniazid administration,[1] and hyperparathyroidism[2]; trauma, due to accident, surgical manipulation, or electric shock; infection—specific infectious diseases, such as mumps and scarlet fever, as well as direct extension of inflammation from foci in the abdomen; vascular factors—obstruction of the pancreatic arterial system by atherosclerosis, essential polyangiitis, or injury from dye injected during translumbar aortography[3]; allergic factors; and neurogenic factors. Most of these have been recently reviewed in detail by Richman[4]; however, some of them will be discussed briefly in order to illustrate the varied mechanisms by which pancreatitis may develop.

Obstruction of the ampulla of Vater, a channel common to both pancreatic juice and bile, may be caused by a calculus, a plug of mucus or inflammatory debris, edema, a tumor, a parasitic worm, or spasm of the second portion of the duodenum as well as of the choledochopancreatic sphincter. The obstruction permits a reflux of bile into the pancreatic ducts, an essential feature of the "common channel" theory. However, acute pancreatitis has been encountered in the absence of an anatomically demonstrable common channel and ascribed to obstruction of the pancreatic ductal system alone as a result of a tumor, calculus, squamous metaplasia, inflammation and edema caused by a penetrating duodenal ulcer, inversion of the duodenal stump during gastric resection, or spasm of the duodenum or of the sphincter surrounding the opening of the pancreatic duct into the duodenum. In these cases the absence of an anatomically demonstrable common channel for bile and pancreatic juice has been used as evidence to eliminate the role of bile in activating the enzymes thought to be responsible for initiating the pancreatitis. Cholangiographic observations, however, suggest that reflux of bile into the pancreatic ducts can

From the Gastro-intestinal Section of the Medical Clinic (Kinsey-Thomas Foundation), Hospital of the University of Pennsylvania.

Read in the Symposium on Pancreatitis before the Section on Gastroenterology and Proctology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

occur regardless of the type of anatomic arrangement of the terminal portions of the common bile and pancreatic ducts. Recently it has been postulated by Hosie and Ziffren[5] that the enzyme collagenase, present in activated pancreatic juice, may escape from the pancreatic ducts into the interstitial tissues of the pancreas and initiate a tissue reaction that transforms trypsinogen into trypsin, which in turn causes the inflammatory process.

The occurrence of attacks two to three hours after the ingestion of a heavy meal or an overindulgence in alcohol has led to the belief that these are important precipitating factors because of their ability to incite an increased secretion of pancreatic enzymes. Alcohol is thought to cause pancreatitis by causing an increased secretion of pancreatic juice against an obstruction due to spasm or edema of the papilla of Vater. The possibility of the existence in alcoholism of acute pancreatitis during the period of alcohol withdrawal after an alcoholic bout should be kept in mind. Sudden death in alcoholics due to acute pancreatitis has been reported by Dalgaard.

Acute pancreatitis has also been known to follow a direct blow to the abdomen, trauma incident to manipulation of a peptic ulcer adherent to the pancreas at laparotomy, biliary tract surgery, splenectomy, and right colectomy, as well as other operations in which the pancreas may be traumatized.

Acute Disease—Clinical Manifestations and Laboratory Findings

Clinical Manifestations.—The severity of an attack of acute pancreatitis depends on the nature of the pathological process present, i. e., edematous or hemorrhagic, as well as such complications as shock, hemorrhage, and sepsis. An attack commonly begins with a sudden pain in the epigastrium at any time of the day or at night during sleep. The pain is usually severe and constant; less often it is cramping and intermittent or dull and poorly defined. It is frequently more intense when the patient is lying supine than when he is sitting or lying on the side with his spine arched forward. Though usually originating in the epigastrium, the pain may also be experienced in other parts of the abdomen and may radiate to the back, substernal area, and flanks. Nausea and vomiting frequently occur soon after its onset. Constipation, as a result of reflex ileus, chemical peritonitis, or administered opiates, occurs more commonly than diarrhea.

A slight fever is usually present, and the pulse rate is increased, especially in the more severe cases. The blood pressure may be slightly elevated but is low in the more critical cases of patients with circulatory collapse, cyanosis, cold and clammy skin, rapid feeble pulse, and subnormal temperature.

The abdomen may be distended early as a result of ileus due to a chemical peritonitis, and peristalsis is diminished or inaudible. The administration of opiates may contribute to the ileus. Tenderness in the epigastrium is almost invariably present and is associated with rigidity. Tenderness may be elicited elsewhere in the abdomen, depending on the sites of seepage of the pancreatic juice.

A mild transient jaundice may be present as a result of associated cholangitis, obstruction of the ampulla of Vater, pressure on the common duct by an enlarged head of the pancreas, or hepatitis. Tetany due to hypocalcemia is occasionally encountered, particularly in the acute hemorrhagic form. Congestion, atelectasis, or a small pleural effusion may sometimes be detected at the base of the left lung. The latter has been ascribed to subdiaphragmatic irritation but has been found to contain significant amounts of amylase. Discoloration of the skin, varying from slate blue to mottled brownish yellow, due to ecchymosis (the color depending on the age of the extravasated blood) occasionally appears in the region of the loins (Gray-Turner sign) or of the umbilicus (Cullen's sign) at about the fifth to the seventh day of the disease. In the more severe cases of pancreatitis, a mass, often firm, fixed, and tender, may be palpable in the epigastrium or in one of the upper quadrants either early or subsequently in the course of the disease. This mass may consist of pseudocyst formation containing necrotic debris, blood, and fluid, of an abscess, or of inflamed mottled omentum studded with multiple fat necroses.

Laboratory Findings.—The leukocyte count is frequently elevated to 10,000 per cubic millimeter or more and, at times, to as high as 20,000 to 30,000 per cubic millimeter. Anemia is ordinarily absent. The concentration of serum amylase is usually increased to more than four to six times normal early in the attack, but no constant relationship exists between the elevation of the amylase level and the severity of the illness. It returns to normal within three to four days in uncomplicated cases. Persistent elevations indicate a continuation, extension, or progression of the process. The concentration of amylase in the peritoneal fluid obtained by abdominal paracentesis has been found to be increased and to remain elevated after the concentration in the blood has returned to normal. The appearance of the aspirated fluid may furnish some information as to the type of pancreatitis present, a yellow, turbid fluid indicating the edematous and a reddish brown color indicating the hemorrhagic form. The concentration of amylase in 24-hour collections of urine is frequently elevated and may remain elevated for longer periods than that in the serum after the acute attack has subsided. The concentration of serum lipase may be increased early in the attack and remain elevated after the serum amylase level has returned to normal. Nardi and Lees[6] recently have found the serum trypsin level to be elevated in patients with acute pancreatitis; they believe this determination to be a more sensitive and reliable index than that of either serum amylase or serum lipase. An increased level of pancreatic desoxyribonuclease greater than five times the highest normal level has been reported in patients with hemorrhagic pancreatitis by Kowlessar and McEvoy.[7]

Other positive laboratory findings[8] may include hypocalcemia, hyperglycemia, hyperbilirubinemia, hypoprothrombinemia, positive findings on cephalin flocculation, thymol turbidity, and thymol flocculation tests, hyperlipemia, glycosuria, ketonuria, bilirubinuria, and an increased concentration of amylase in the urine.

Acute Disease—Diagnosis

The diagnosis of acute pancreatitis usually depends on the finding of a high serum amylase level in a patient with acute severe pain in the upper abdomen and tenderness, vomiting, fever, increased pulse rate, and leukocytosis.

Certain roentgenographic procedures may be helpful in the diagnosis. A survey film of the abdomen may reveal a "sentinel loop" of localized paralytic ileus, usually in the left mid-portion of the abdomen, calcification in the region of the pancreas, or the "colon cut-off" sign. The latter consists of an isolated gaseous distention of the ascending colon and hepatic flexure due to partial obstruction caused by spread of the inflammatory process from the head of the pancreas, as reported by Price in 1956. The barium meal study may disclose the "papillary sign," an unusual prominence of the papilla, as well as evidence of extrinsic pressure on the stomach, duodenal loop, or left half of the transverse colon. Occasionally, the diagnosis is difficult and, at times, impossible without resorting to laparotomy.

In the differential diagnosis, other causes of pain in the upper abdomen also require consideration. Perforated peptic ulcer is ordinarily associated with a greater degree of abdominal wall rigidity and can readily be differentiated by the demonstration of free air in the uppermost portions of the abdomen on a survey roentgenogram. Biliary colic is usually associated with tenderness in the region of the gallbladder. The patient, as a rule, does not appear as sick as does the one with acute pancreatitis. The pain of biliary colic does not last as long as that of pancreatitis, tends to spread and progress less, and may be in some cases temporarily relieved by nitroglycerin. Peritonitis due to causes other than a ruptured peptic ulcer is not usually preceded by the severe prostrating epigastric pain of acute pancreatitis. A moderately elevated serum amylase level in certain patients with peritonitis may be encountered and prove misleading if this criterion alone is used. Intestinal obstruction may be differentiated on auscultation by the high-pitched peristalsis occurring in regular periodic rushes (unless an opiate was recently administered) and on survey roentgenograms of the abdomen by the demonstration of gas-fluid levels. Occlusion of the mesenteric vessels, rupture of an aneurysm, and other causes of intra-abdominal pain may be differentiated, except under unusual circumstances, by normal serum amylase levels.

Coronary occlusion may be confusing, especially when pancreatitis is associated with shock. Acute pancreatitis has been reported to cause electrocardiographic changes[9] suggestive of myocardial infarction during the period of increased serum enzyme concentration. The changes include depression of the S-T segment, inversion of the T waves, and prolongation of the Q-T interval. They have been ascribed to a toxic substance in the blood stream arising from the pancreas, to coronary insufficiency secondary to shock and hypotension, and to the direct action of pancreatic enzymes on the structures of the heart. The electrocardiographic changes are not specific for acute pancreatitis but may be observed in a variety of conditions in which shock and electrolyte disturbances are present.

The finding of an elevated serum amylase level does not always mean that pancreatitis is responsible. The administration of opiates has been reported to be followed by a moderate elevation of serum amylase level, which may persist for as long as 24 hours. Usually the levels reached are not as high as those encountered in the early phase of acute pancreatitis. The serum amylase level may be elevated when renal function is impaired to a degree causing an elevation of blood urea nitrogen level. Sachar and Weinhaus, in 1956, reported an impaired renal clearance of pancreatic amylase which they thought was responsible for hyperamylasemia in a patient without obvious renal or pancreatic disease.

Acute Disease—Complications and Treatment

Complications.—The acute process may subside, or it may remain active until shock or sepsis terminates the picture. When death occurs within a few hours of the onset of the pain, it is usually the result of shock. The shock has been ascribed to a decreased blood volume occurring when the edema first appears.[10] When death occurs after three or more days have elapsed, it is usually the result of sepsis or severe internal hemorrhage. The peritonitis at first is chemical in nature, but, subsequently, secondary bacterial invaders appear, including gas-forming anaerobes, to cause a bacterial peritonitis, septicemia, septic thrombosis of the portal vein, or multiple abscesses. Shock may occur as a result of excessive blood loss into the peritoneal cavity due to erosion of a sizable blood vessel. Other hemorrhagic manifestations that may develop include purpura, hematemesis, melena, and extravasation of blood into the mediastinum or abdominal wall. Obstruction of the jejunum or of the colon may occur as a result of involvement by an inflammatory mass about the body and tail of the pancreas.

Diabetic coma may complicate acute pancreatitis.[11] The distinguishing characteristics of the diabetic coma in patients with acute pancreatitis have been said to be a rapid fall in blood sugar levels in response to insulin, a water-resistant dehydration that responds to the expansion of the blood volume, brief periods of increased production of insulin or reduction of glucagon, severe degree of prostration, abdominal pain of pancreatic distribution, abdominal tenderness on palpation, sweating at some stage of the disease, elevated serum amylase levels, and failure to improve despite therapy.

Treatment.—In the past, many patients with acute pancreatitis were subjected to laparotomy because of the uncertainty of making an absolute diagnosis on purely clinical evidence. The mortality was high. During recent years increased confidence in the clinical diagnosis, resulting from more widespread use of the serum enzyme tests, has led to increasingly conservative management. Because of this and the improved methods of combating shock and sepsis in critically ill patients, the mortality from severe pancreatitis has decreased. Unfortunately, a certain number of patients have died when either medical or surgical therapy was used alone, indicating that the manner of treatment must be individualized and the plan of therapy chosen which offers the best prognosis. When operation is necessary it should be carried out at an appropriate time after the onset of acute symptoms and not during the early hours, unless suppuration, severe hemorrhage, or spreading peritonitis develops.

Conservative management includes bed rest and nothing given by mouth until the acute symptoms have subsided. Continuous gastric suction is maintained through a nasogastric tube in order to remove acid gastric juice, a natural stimulant to pancreatic secretion, and to reduce ileus. Atropine, 0.4 to 0.6 mg., is given by injection every three to four hours to suppress pancreatic as well as gastric acid secretion. Meperidine is preferred to morphine for pain because of the greater tendency of the latter to cause nausea and its demonstrated ability to cause spasm of the sphincter of Oddi with a resultant increase in pressure within the pancreatic ductal system. Tetraethylammonium (Etamon) chloride, 1 to 5 ml. of a 10% solution given intravenously every four hours, has controlled pain satisfactorily in some instances. At times, intractable pain has been promptly relieved by paravertebral, epidural, or splanchnic block.

Shock is combated by infusions of plasma, albumin, or blood. Parenterally given fluid, in the form of isotonic sodium chloride solution, is administered to overcome dehydration and to replace the chloride lost by vomiting and gastric aspiration. Potassium should be administered along with sodium to patients in whom large amounts of gastric content are aspirated because large amounts of potassium may be lost in this manner. Glucose solutions should not be given when a hyperglycemia exists, unless covering amounts of insulin (5 to 10 units of regular per 25 Gm. of glucose) are given. When insulin is used, great care must be exercised to avoid a fall in the blood sugar level to hypoglycemic levels. Calcium gluconate and vitamin K are injected parenterally when the serum calcium or plasma prothrombin levels are low. A broad-spectrum antibiotic may be administered in an attempt to prevent or suppress suppurative complications. Beneficial results from the use of cortisone have been reported in several instances. Dreiling and co-workers,[12] however, feel that the use of the steroids should be limited to patients with acute pancreatitis who have adrenocortical deficiencies, because of the experimental production of pathological damage to the acinar tissue of the pancreas that has followed the administration of these compounds, as well as because of postmortem evidence that similar changes occur in patients on steroid therapy. They found a depressant effect of steroids on the external secretion of the pancreas, which they ascribed to an interference with the proper functioning of acinar tissues.

The patient is permitted to take fluid and bland foods by mouth as soon as the acute symptoms subside. Thereafter, measures to eliminate such precipitating factors as cholelithiasis, alcoholism, peptic ulcer, or hyperparathyroidism should be instituted for prophylactic purposes. It should be pointed out that a cholecystogram may reveal a nonfunctioning gallbladder if performed too soon after an attack of pancreatitis. At least a month and sometimes longer should elapse before any significance need be attached to such a finding unless confirmatory evidence of cholelithiasis is obtained by biliary drainage. A glucose tolerance test should be performed on all patients to detect latent diabetes unless a diabetic state is obvious.

Chronic Disease—Etiology and Clinical Manifestations

Etiology.—Chronic pancreatitis is encountered most frequently during the fifth and sixth decades of life. It is usually caused by repeated attacks of acute pancreatitis. It may also occur as a result of involvement by tuberculosis, syphilis, or hemochromatosis. The development of chronic pancreatitis in younger individuals on a hereditary basis has been reported by Comfort and associates. It is inherited through a non-sex-linked Mendelian dominant gene and is accompanied by a defect in amino acid metabolism, the distinctive feature of which is an excessive lysinuria.[13] It is not associated with gallstones, and alcoholism is not a factor.

Clinical Manifestations.—The clinical manifestations of chronic pancreatitis depend on the stage of the disease. During a relapse the manifestations are similar to those of acute pancreatitis. Subsequently, the clinical picture may be quite variable, depending on the degree to which the acinar and islet tissues are destroyed, the nature of the associated disease process, the presence or absence of calcification, and whether obstructive jaundice is produced. The clinical picture may also be modified by alcoholism and drug addiction, as well as the manifestations of hyperparathyroidism.

The chronic relapsing form is characterized by recurring attacks of acute and severe pain interspersed with variable intervals of relative freedom from symptoms. The painful episodes, associated with nausea, vomiting, constipation or diarrhea, fever, chills, tendency to tachycardia, and, sometimes, jaundice, may occur as infrequently as once in four years or as often as once daily or weekly; they have been known to last from less than one hour to 35 days. The pain is most frequently experienced in the epigastrium, then, in order of frequency, in the right upper quadrant, the left upper part of the abdomen, the right lower quadrant, and the periumbilical region. It may also be generalized. Radiation to the back is common. The pain, when typical, is severe and steady and tends to make the patient flex his spine forward for relief. The onset may be gradual or abrupt. Frequently, it gradually increases in severity, reaches a plateau, and then gradually declines. It may be temporarily relieved by opiates. Some patients have difficulty in describing the exact character of the pain but readily admit its marked severity.

Physical examination of the abdomen during an acute painful episode may reveal the signs of acute pancreatitis. In addition, an epigastric mass may be found, consisting of pancreas, enlarged because of inflammation or contained cysts, and, in some cases, hepatomegaly as a result of fatty infiltration. Early in the acute episode, the function of the acinar and islet cells is frequently disturbed. Eventually, the cellular disturbances become more permanent and cause steatorrhea and diabetes mellitus. Loss of weight, despite a good appetite and a satisfactory calorie intake, occurs as a result of faulty digestion and absorption of fat. The character of the stools changes, and their number increases when steatorrhea develops. The characteristic stool is bulky, frothy, glistening, pale in color, and foul-smelling. Sometimes, diabetes and/or steatorrhea first attract attention to the existence of a destructive inflammatory process in the pancreas.

Occasionally, the clinical picture is dominated by a progressive jaundice occurring as a result of compression of the common duct by the enlarged head of the pancreas. In such cases, the clinical diagnosis is usually that of carcinoma of the pancreas, and the true nature of the process is disclosed at laparotomy. In rare instances, obstruction of the colon thought to be due to a carcinoma is found to be the result of stenosis secondary to chronic pancreatitis. An instance of portal hypertension with hemorrhage from esophageal varices, secondary to recurrent pancreatitis, was reported by Snider and Nelson. They felt that the portal vein was probably compressed by the inflammatory process in the head and neck of the pancreas. The development of chronic pancreatitis without a history of acute painful episodes has been reported by Bartholomew and Comfort.

Chronic Disease—Diagnosis

Early in the course of the disease, the diagnosis is based on a history of recurring attacks of acute pancreatitis having the clinical and laboratory characteristics previously described. Subsequently, as the pancreas becomes progressively and extensively damaged, the functioning acinar cells may be too few to give an elevation of values for serum enzymes during the painful seizures and the diagnosis is based on the clinical picture, together with the laboratory findings, including hyperglycemia, glycosuria, a diabetic type of glucose tolerance curve, and a decreased volume and concentration of one or more of the pancreatic enzymes in the duodenal juice before and after the administration of a stimulant, such as secretin, bethanechol (Urecholine) chloride, or methacholine (Mecholyl). An increased amount of nitrogen and of total and unsplit fat may be detected in the feces while the patient is maintained on a diet containing fixed amounts of fat, protein, and carbohydrate. Evidence of impaired digestion and absorption of neutral fat may also be obtained by determining blood and stool concentrations of radioactive iodine (I^{131}) after feeding fat so labeled.

Roentgenographic demonstration of calcification in the region of the pancreas furnishes additional evidence of chronic pancreatitis. Such calcification, on the basis of relapsing pancreatitis, has been observed to become evident anywhere from 1 to 22 years after the onset of pain. The possibility of the existence of a parathyroid adenoma should be kept in mind in all cases of diffuse calcification of the pancreas. Other roentgenographic findings may include widening of the duodenal loop, compression or indentation of the duodenum, compression of the antrum or posterior wall of the stomach, and anterior displacement of the stomach. Disturbances in the motor function and pattern of the small intestine may be detected. Their presence depends on the blood sugar level at the time of the examination, the presence or absence of hypoproteinemia, and abnormal serum potassium and calcium levels. A cholecystogram may reveal a normally functioning or a nonfunctioning gallbladder, with or without evidence of calculi.

In the differential diagnosis of the acute painful episodes of chronic relapsing pancreatitis, the same causes of abdominal pain as were discussed in the section on acute pancreatitis are to be kept in mind. In the differential diagnosis of chronic pancreatitis associated with steatorrhea, sprue must be considered. Sprue is characterized by relapses and remissions of symptoms, consisting of anorexia, flatulence, loss of weight, passage of foul-smelling flatus and bulky stools, a flat oral glucose tolerance curve, and a lack of the laboratory abnormalities characteristic of a damaged pancreas. Intestinal lipodystrophy (Whipple's disease) may also be associated with steatorrhea as a result of deposits of fat and fatty acids in the intestinal and mesenteric lymphatic tissues. Associated clinical manifestations of intestinal lipodystrophy may include flatulence, arthritis, loss of weight, anemia, edema, ascites, cutaneous pigmentation, and evidence of a low-grade inflammatory involvement of the peritoneal, pleural, and pericardial cavities.

When obstructive jaundice is present, a differential diagnosis between chronic pancreatitis and carcinoma of the pancreas is not possible on the basis of the fat content of the stools, the glucose tolerance curve, the concentration of pancreatic enzymes in aspirated duodenal juice, or the roentgenographic demonstration of obstruction or distortion of the duodenum or stomach. The finding of malignant cells in aspirated duodenal juice or the demonstration of metastases supports a diagnosis of carcinoma. Carcinoma is more likely to be associated with anorexia, cachexia, and pain, which is usually less acutely severe but more persistent. It is intensified when the patient is lying in the supine position and relieved by forward flexion of the spine as in the fetal or knee-chest positions. Occasionally, at laparotomy, a biopsy of the pancreas will reveal extensive fibrosis and chronic inflammation secondary to an undetected carcinoma of the pancreas. The inflammatory reaction is secondary to the malignancy. Bartholomew and associates have noted the development of carcinoma of the pancreas in patients with long-standing pancreatitis associated with calcification. In Senior's [14] series of 96 patients collected at the University Hospital and thought to have chronic pancreatitis, 12 eventually were discovered to have carcinoma of the pancreas. Exploration and biopsy of the pancreas had been done in some of the 12, the biopsy disclosing only evidence of chronic pancreatitis.

The problem is a difficult one, and differentiation is not always possible clinically, grossly at laparotomy, or even on biopsy. Some patients with chronic relapsing pancreatitis have had their symptoms ascribed to psychoneurosis. One must always bear in mind that the clinical picture may be confused by alcoholism or drug addiction.

Chronic Disease—Course, Prognosis, and Treatment

Course and Prognosis.—The course of chronic relapsing pancreatitis depends to a large extent on the maintenance and persistence of the etiological factors and on the degree to which the pancreas is damaged. Eventually, the state of chronic pancreatitis is reached, with varying degrees of pancreatic insufficiency as manifested by diabetes, steatorrhea, and calcification. Death may occur at any time from intercurrent infection, pancreatic necrosis, peritonitis, abscess, septicemia, pyelophlebitis, complications of diabetes, intra-abdominal bleeding, or gastrointestinal hemorrhage from peptic ulcer or gastroduodenitis.

Medical management in the presence of severe pain is unsatisfactory and is often complicated by drug addiction and alcoholism. A variety of surgical procedures has been employed, with results sometimes satisfactory but often as unpredictable as those of medical therapy.

Treatment.—Chronic relapsing pancreatitis may be treated medically, surgically, or by a combination of these methods.

Medical treatment is purely palliative and consists of relief of pain, substitution therapy in patients with pancreatic insufficiency, and eradication of etiological factors of a nonsurgical nature. The treatment of the painful attack is similar to that of acute pancreatitis. In the intervals between attacks, and especially when pancreatic insufficiency develops, the diet should be high in carbohydrate and readily assimilable protein but low in fat. If gastric hyperacidity exists, gastric secretory depressant drugs should be administered in an attempt to prevent peptic ulceration of the duodenum, to which such patients are predisposed when the amount of bicarbonate eliminated by the diseased pancreas becomes decreased. The administration of predigested protein in supplemental feedings may aid in maintaining a positive nitrogen balance. An active form of pancreatin is administered in sufficient amounts (up to 3 Gm. with each meal) to decrease steatorrhea and azotorrhea as well as a multivitamin capsule daily to insure an adequate intake of the essential vitamins. Bile salt preparations may be administered to increase the absorption of fat-soluble vitamins, especially in patients with jaundice, as in these the bile salt concentration may be decreased. Choline or methionine are indicated for those patients whose protein intake is inadequate in an attempt to prevent subsequent development of a fatty liver and possible cirrhosis. Diabetes should be controlled with insulin. The use of alcoholic beverages should be discontinued by those in whom alcoholism appears to be the major precipitating factor. Gastroduodenal disease, when present, should be properly treated.

Jaundice due to obstruction of the common bile duct by an enlarged head of the pancreas requires a surgical procedure, such as a cholecystenterostomy. Cholelithiasis and choledocholithiasis should be treated surgically in an attempt to relieve those patients in whom biliary tract disease may be the predisposing factor. For repeated attacks of severe pain, not controlled by conservative measures, a variety of surgical procedures has been employed.

PROGRAM ON MEDICAL ASPECTS OF AUTOMOBILE INJURIES AND DEATHS

Fletcher D. Woodward, M.D., Charlottesville, Va.

The American Medical Association, appalled by the rising tide of deaths and injuries occasioned by the automobile and realizing that a certain undetermined percentage were due to physiological conditions, pathological states, emotional disturbances, or drugs and alcohol, appointed a committee, through its Board of Trustees, to study and report on the medical aspects of automobile crash injuries and deaths in 1955. This committee was to determine the magnitude of the problem, study the epidemiology and methods of prevention and cure primarily from a purely medical standpoint, and determine the role of the physician in obtaining these objectives.

The first endeavor of the committee was to acquaint the medical profession with these broad aspects by presenting a symposium at the 1956 meeting in Chicago. At the same time a rather comprehensive scientific exhibit was also presented. This effort was well received and many requests for reprints were received from both American and foreign physicians. A 15-minute movie called "On Impact" was also prepared in collaboration with the Ford Motor Company. This film depicted some of our efforts toward curbing this rising tide of injuries.

The committee decided that its first duty was to prepare three pamphlets. The first one has been written at the popular level in lay language to serve as a guide to the patient in answer to the query "Are you fit to drive?" The first 100,000 copies were paid for by the Association of Casualty and

Clinical Professor of Otolaryngology, University of Virginia, Department of Medicine. Chairman, American Medical Association Committee on Medical Aspects of Automobile Injuries and Deaths.

Read in the Session on Traffic Accidents before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

Surety Companies of New York. The Center for Safety Education of New York University collaborated in this venture.

The second pamphlet is designed to serve as a guide to the physician in determining a patient's fitness to drive. This is a pioneer work; it has been completed and will be published in a future issue of THE JOURNAL. The material will be presented under such sections as cardiovascular and ophthalmological aspects. The third and most comprehensive pamphlet will be written as a guide to examining police officers and state traffic agencies and will set certain physical standards. We have also suggested that each state medical society appoint a traffic safety committee to work with various state agencies.

Our studies over the past two years have shown that there are many divergent medical interests in many phases of this problem. For instance, we are working through the National Safety Council in establishing uniform and reasonable speed limits. We are collaborating with the American College of Surgeons for safer automobile design. We are working through the Roberts' Congressional Committee to this same end and to assist in providing new and needed legislation. We have given our conclusions in regard to alcohol blood levels to the legal division of the A. M. A. and to the Committee on Alcohol. Finally, we hope to establish a set of uniform objectives that will guide us and the various state and local safety committees.

MEDICAL GUIDE FOR PHYSICIANS IN DETERMINING FITNESS TO DRIVE A MOTOR VEHICLE

Seward E. Miller, M.D., Ann Arbor, Mich.
and
Harold Brandaleone, M.D., New York

Traffic accidents killed about 40,000 individuals last year and injured about 1,500,000. This constitutes one of the nation's largest unsolved health hazards. Physicians have not realized or accepted their responsibilities in this health problem as they have with heart disease, cancer, and other disease entities.

Since the human factor is the most important single factor responsible for motor vehicle accidents, the physician must initiate and participate in research designed to determine the relationship between physical and emotional factors and the etiology of accidents. He is the only person able to ascertain the physical, mental, emotional, or physiological impairments of an individual and to evaluate these disabilities in relation to safe driving ability. It is the responsibility of the physician to persuade a patient to discontinue driving when he no longer is able to drive with safety.

Motor vehicle drivers may be classified as two general types: civilian or private drivers and commercial or industrial drivers. The latter group includes transportation drivers. The required physical and mental standards for commercial vehicle drivers, especially transportation drivers, should be more rigid than for civilian drivers. The civilian driver should be examined every three years up to the age of 45 years and every two years thereafter. The commercial vehicle driver should have a preplacement examination and a periodic examination every two years up to the age of 45 years and annually thereafter.

A patient may incur temporary or permanent disability which should prevent him from driving. He may be suffering with an illness that directly or indirectly interferes with his driving ability, making it unsafe for him to drive until the condition is controlled. For example, everyone agrees that a diabetic who takes insulin and is subject to hypoglycemic reactions should not drive, nor should a patient with uncontrolled convulsions or a cardiac condition that might cause sudden loss of consciousness.

The Committee on Medical Aspects of Automobile Injuries and Deaths has prepared a medical guide for physicians in determining fitness to drive a motor vehicle which will be useful in advising patients on their fitness to drive. The guide will be published in a future issue of THE JOURNAL.

1634 University Hospital (Dr. Miller).

ROLE OF PRIVATE PHYSICIAN IN MOTOR VEHICLE ACCIDENT PREVENTION

James L. Goddard, M.D., M.P.H., Washington, D. C.

The physician can help in at least five ways to reduce the damage done to human lives by motor vehicle accidents. He can "teach while treating" by explaining the relation of defects and diseases to accidents. He can and should make sure that community emergency services are improved. He can make sure that emergency rooms in hospitals are organized in such a way that a sudden influx of accident victims will not create chaos. He can influence the development of sound medical standards for driver licensing. He can engage in research on the causes and prevention of accidents. The fact that more than 4 million persons require physicians' services because of motor vehicle accidents represents at once a responsibility and an opportunity in the field of preventive medicine.

The practicing physician has long been concerned with the problems generated by motor vehicle accidents, primarily, the provision of medical services to the injured. The true magnitude of his task has only come to light in the past year. The recent report of the National Health Survey indicates that 2,500,000 persons were injured in motor vehicle accidents from July 1 to Dec. 31, 1957. Approximately 85% of those injured required medical attention. This means that each year over 4 million persons require physicians' services because of motor vehicle accidents.

It is, therefore, not surprising that physicians are now looking beyond the immediate task of restoring accident victims and asking that more resources be devoted to the prevention of accidents and resultant injuries. Individually and collectively, physicians have expressed their concern with the injury-producing potential of the automobile. Through the American Medical Association and other medical organizations, this concern has been voiced by asking that more attention be given to the design of vehicles which will minimize the danger of injury, should an accident occur.

Through improvements in clinical knowledge, methods, and skill, physicians have helped to hold the total number of fatalities at a rather fixed level. No precise measure of this contribution can be made, but it is known that fatalities have remained constant in spite of a tremendous increase over the past 20 years in the total miles traveled annually.

Two years ago the Committee on Medical Aspects of Automobile Injuries and Deaths, of the American Medical Association, was organized in order to utilize more effectively the interests and resources of the medical profession towards the solution of this complex problem. As indicated by its name, the committee has restricted its efforts to a particular segment of the problem. The committee recognizes that, to be successful, physicians must not dissipate their interests and energies by going into aspects of the problem in which they are not competent. The physicians must examine their capabilities and accept responsibility for suitable activities.

The following activities are proposed as meeting the above criteria. If implemented by every physician, they would result in significant decreases in deaths, injuries, and disabilities. First, there are the many things that can be done as a physician, working with patients. The traditional physician-patient relationship provides the ideal situation for patient guidance in accident prevention.

One thinks immediately of the obvious opportunity which occurs when the physician is actually treating an injury and can "teach while treating," by explaining accident causation and warning against potential future hazards. I use the term "ideal" because no learning situation could be better calculated to produce attention and acceptance on the part of the patient.

Beyond this special situation, however, additional guidance possibilities are almost limitless. When the physician, in the course of his normal practice, discusses with patients conditions or disabilities that could interfere with the ability to drive a motor car, there should be frank counseling on this subject, and the hazards of driving should be plainly indicated. Possible relationship of side-effects of medication on driving ability should be stressed.

In addition, inadequate vision and hearing, diabetes, epilepsy, and heart and neuromuscular conditions (to name but a few) can create serious driving hazards. The physician's advice in this connection will carry weight with the patient, while the latter may not otherwise give proper emphasis to the relationship between his condition and his driving capacity.

Chief, Accident Prevention Program, Public Health Service, U. S. Department of Health, Education, and Welfare.

Emergency Services

The second major responsibility of the medical profession is to improve community emergency services. The care and transport of the injured is a matter that has not received the attention it deserves. Studies made during World War II and the Korean war demonstrated the great values of properly administered first aid and careful handling during transport to the medical facility. Implicit in good community emergency services, whether provided by public or private organizations, are the following standards: (1) trained drivers and attendants for all ambulances, (2) continued supervision of emergency services, and (3) adequacy of equipment.

There are several ways of achieving these objectives. In some areas full-time rescue squads are in existence. The physician, through his local medical society, can provide the training that is indicated. Where a community relies on private services it has proved feasible, in some areas, to require training of drivers and attendants as a prerequisite to licensing. In some communities the local health department is the licensing and supervisory agency. But in each instance the best interest of the patient is served when the physicians of the community are active in the training and continued supervision of the services.

Third, and equally important in any community, is the status of the hospital emergency services. A direct contribution can be made here if physicians will exert themselves to improve and coordinate the services in hospital emergency rooms. The team approach is all important in rendering these services, which have so great an influence on minimizing the effects of accidental injury, and much remains to be done to raise the standards of hospital emergency rooms throughout the country.

Specifically, the emergency rooms should be organized in such a way that a sudden influx of accident victims will not create chaos. This means better planning and supervision on the part of the attending staff. This important phase of patient care cannot be delegated to the intern and resident staff. Ancillary services, such as x-ray and laboratory, should be available either immediately or within a few minutes, and the equipment must be adequate.

These three activities, patient guidance, improvement in community emergency services, and improvements in hospital care, require the support and participation of physicians individually and at the community level.

Other Contributions by Physicians

Working through the State Medical Society, the practicing physician can make a fourth major contribution. I refer to the development of sound medical standards for driver licensing. This can be achieved by providing the motor vehicle administrator with a technically competent advisory group. This advisory group can also provide guidance to the motor vehicle administrator in the handling of problem cases. In some states the Medical Society and the State Health Department have worked jointly with the licensing authority to establish special procedures for the supervision of drivers thought to represent added risks, e. g., epileptic.

The importance of a physician's role in research hardly needs emphasis. Through such cooperative endeavors as the Cornell Automotive Crash Injury Research Project, he has made a significant contribution. It is not unreasonable to expect an increased interest in accident prevention research. By virtue of his access to the clinical data and his training, the physician is particularly well qualified to carry out such investigations.

Thus the physician, as a physician, can make five contributions: (1) give individual patient guidance, (2) improve community emergency services, (3) improve hospital emergency services, (4) develop medical standards for drivers' licensing, and (5) engage in auto accident research.

In addition, as a leading member of the community, the physician can make a significant contribution to accident prevention by lending his support to every worthwhile local effort to cut the accident rate. For example, driver education, organized at the high school level, has demonstrably improved teenage driving habits, and equally gratifying results can be anticipated from adult driver education. The encouragement and development of adequate driver training programs in a community require organized community effort; physicians, acting either individually or as medical society members, can exert leadership in this important area. The physician's word will also carry weight in any community when he supports movements for improved enforcement of traffic laws.

Public health officials throughout the United States are laying special emphasis on better first-aid training. Here the physician is the indispensable person. The physician can help by emphasizing the need for first-aid training and its benefits, and by counseling the instructors. Although my topic has been the physician's role in accident prevention, the cooperative relationship between the private physician and the public health profession in this vital field of activity should also be mentioned. The stimulation and guidance of community action to reduce the terrific toll of death and disability from accidents in this country is an important responsibility of the State and local health departments, aided by the Public Health Service.

Through professional education and education of the general public, it is hoped that a significant contribution to accident prevention can be made in the years ahead. Local education campaigns of this nature can succeed only with the enthusiastic support of appropriate local groups, and no community group is a more necessary partner in this undertaking than the private physicians.

PSYCHOLOGICAL AND PSYCHOPHYSIOLOGICAL FACTORS IN MOTOR VEHICLE ACCIDENTS

FOLLOW-UP STUDY

John J. Conger, Ph.D., Herbert S. Gaskill, M.D., Donald D. Glad, Ph.D., Linda Hassel, Ph.D.,
Robert V. Rainey, Ph.D., William L. Sawrey, Ph.D.
and
Eugene S. Turrell, M.D., Denver

A continued and more intensive investigation of the personal factors that might make some drivers more susceptible than others to automobile accidents was carried out in 20 airmen. Ten had been held officially responsible for two or more accidents in the preceding four and one-half years. They were compared with 10 who had no record of accidents in the same period. The tests included a structured psychiatric interview and a routine psychological examination as well as other functional tests. No differences were found between the two groups in either intelligence or psychophysiological responsivity. However, in the area of personality functioning, accident-repeaters displayed significantly poorer control of hostility, lower tension-tolerance, higher separation anxiety and dependency needs, and extremes both of egocentricity or sociocentricity and fantasy-preoccupation or unreflectiveness.

It has long been recognized that motor vehicle accidents are not, as the term implies, simply a function of what "erring men call chance." It has been demonstrated, for example, that some roads are safer than others and that certain times of the day are safer. There is also some evidence to indicate that certain people are more likely to have accidents than others, and a number of attempts have been made to determine whether such persons possess unique personal characteristics which differentiate them from their fellowmen who do not have accidents.

For example, in various studies the accident-repeater and nonaccident drivers have been compared on a wide variety of psychophysical and psychophysiological measures, on measures of personality structure and functioning, and on social history variables. Many of these studies have yielded equivocal or contradictory results, probably partly because of real differences between the populations studied, but probably also in many cases because of methodological deficiencies in the design of the studies—including failure to control for variations in accident exposure, unreliability in the accident criteria employed, and lack of objectivity in the measurement of driver characteristics.

The weight of the evidence, however, suggests that in most populations accident repeaters are likely to differ from other drivers in their personal characteristics and, further, that psychological variables are more likely to prove discriminating than measures of physiological or psychophysical functioning.[1]

The purpose of the present paper is to describe the most recent findings in a four-year investigation of the role of personal and interpersonal factors in determining accident frequency and severity among airmen stationed at Lowry Air Force Base in Denver. In previous work on this project, 264 subjects were administered a wide variety of psychiatric and psychological techniques, including structured psychiatric interviews, objective and projective personality tests, attitude and interest tests, and a number of psychophysical measures.

As reported previously,[2] most of these measures failed to discriminate consistently with repeated samples between high-accident, middle-accident, and nonaccident rate airmen. For example, while a number of psychophysical measures, such as discrimination reaction time and depth perception, and a number of objective personality tests, such as the Minnesota multiphasic personality inventory and the Thurstone temperament scale, appeared promising initially, they failed to survive in cross-validation. One type of measure, however, proved extremely stable, namely, measures of the individual's value system.

Of the six scales contained in a modification of the Allport-Vernon-Lindzey study of values, developed by Dr. Jerome Levy of the project staff, three scales—those dealing with esthetic, theoretical, and religious concerns—proved highly discriminating, both initially and in later cross-validation samples. The remaining scales (economic, political, and social) did not. The accident subjects were consistently less oriented toward religious values, and

more toward esthetic and theoretical values than the nonaccident subjects. As might be expected, the mean scores of the middle-accident subjects fell in the middle range between the high-accident and nonaccident subjects.

On the basis of the scores on this test, it was possible to differentiate successfully between high-accident and nonaccident subjects in approximately 73% of cases in repeated samples over several years. While this degree of predictive success was encouraging, the authors felt that not enough was yet known of the personality structure and functioning of these subjects to interpret the psychological meaning of these test findings with confidence.

The primary aim of the present study, therefore, was to obtain a broader understanding of the characteristics of these two groups. The subjects were 10 high-accident and 10 nonaccident rate airmen, selected to be representative of the over-all accident and nonaccident populations. Each of these subjects was studied intensively. High-accident subjects were defined, as in the previous study, as individuals who had two or more accidents for which they were officially held responsible in the past four and one-half years, at least one of which occurred within the year immediately preceding testing. Nonaccident subjects were defined as individuals who had no record of accidents, according to either official records or the individual's subjective report, during the past four and one-half years. Data obtained fell into two general categories: clinical studies and objective testing.

Clinical Studies

The major portion of the present study involved an intensive clinical evaluation of 10 high-accident and 10 nonaccident rate subjects. Each subject received a structured psychiatric interview aimed at obtaining information regarding his social history and personality development as well as his current attitudes, interests, behavior, and personality functioning. This interview was tape-recorded for future reference.

In addition, each subject received a routine psychological examination by one of the clinical psychologists on the staff of the University of Colorado Medical School. The following battery was administered at one sitting: the thematic apperception test (10 cards), the Rorschach test, the Wechsler-Bellevue intelligence scale (four subtests), and the Sacks sentence completion test. In each case, the psychologist was asked to prepare a general evaluation of the subject, noting such things as over-all assets and liabilities, basic character traits, and defense mechanisms employed. In view of the intention of the investigators to avoid as much as possible influencing the specific content of the reports, no further instructions were given.

The interviews were conducted by two project members, a psychiatrist and a psychologist; the psychological testing was done by five clinical psychologists. Assignment of interviewers and testers to subjects was done randomly, and in neither case did the examiner have any knowledge of the subject's accident status.

Thus, the basic data employed in this phase of the study consisted of (1) psychiatric interview transcripts and (2) test protocols and individual psychological reports. These data were then rated independently for 13 variables hypothesized to be significantly related to accident frequency and severity on the basis of previous work. In addition, two over-all personality-type descriptions were presented, one hypothesized to represent a composite accident individual and the other a composite nonaccident individual. Raters were asked to rate subjects as more like one or the other of these two personality types.

In the case of the interview, two judges were employed—the original interviewer and the alternate interviewer. Similarly, in the case of the psychological reports and original test protocols (which were rated as a composite unit), two judges were also employed—the original tester and one of the other testers. Preliminary analysis showed a high degree of agreement between raters. In view of this evidence of reliability, the average rating of the judges was employed in all cases. The 13 variables rated by the judges included the following criteria.

Variables

1. *Amount of Underlying Hostility.*—Ratings of hostility (whether expressed or not, and regardless of how expressed) were made along a continuum from negligible to excessive. This variable was included because it has frequently been mentioned in the literature as distinguishing accident from nonaccident subjects. It was the investigators' opinion, however, that this variable was not directly related to accident susceptibility. Rather, it was felt that the importance of underlying hostility as a factor in accident susceptibility could be evaluated only in relation to the individual's capacity for control. This hypothesis led to inclusion of the next two variables.

2. *Strength of Destructive, Hostile Impulses Directed Toward Environment in Relation to Ability to Control These Impulses.*—Possible ratings of hostile impulses to environment ranged all the way from "hostility moderately or much greater than control" to "excessively greater control in relation to amount of hostility." It was predicted that accident subjects would show relatively less capacity for control in relation to strength of hostility.

3. *Aggression and Behavior.*—Raters of aggression and behavior were asked to judge which of the following descriptions most nearly character-

ized the subject: (*a*) Consistently, openly belligerent; (*b*) usually controlled but occasional outbursts of belligerence; (*c*) covertly hostile (passive-aggressive, critical, carping, indirectly aggressive toward others); (*d*) realistic, flexible, appropriately assertive; (*e*) passive, unassertive (fear of retaliation for expression of aggression); (*f*) unassertive, low drive, low energy; (*g*) depressed; and (*h*) other, to be briefly described. It was predicted that accident subjects would be more likely to fall in categories *a* through *c*, nonaccident subjects into categories *d* through *g* (only one subject fell in category *h*, about which there was no prediction).

4. *Reality Orientation.*—Possible ratings of reality orientation (realistic appraisal of own motives and environmental forces affecting subject—extent to which behavior is directed toward meeting subject's own enlightened self-interest) ranged from very poor (definite breakdown, at least occasionally in reality-testing) to excellent. It was predicted that nonaccident subjects as a group would tend to show more adequate reality orientation.

5. *Egocentric Versus Sociocentric.*—Ratings ranged from very egocentric (very self-centered, little interest in rights of others or respect for their feelings) through a neutral mid-point (neither markedly egocentric nor sociocentric, fairly good balance between satisfying own needs and respect for needs and feelings of others) to very sociocentric ("overdetermined" awareness of, interest in, and respect for rights and feelings of others). It was predicted that accident subjects would be more likely to cluster at the extremes of the continuum, with nonaccident subjects tending to fall around the midpoint.

6. *Conventionality.*—Conventionality ratings were based on the extent to which the individual was conventional in his conscious thinking, values, interests, and impulses to action, as possibly distinguished from, for example, underlying unconscious needs, or overt behavior in certain life situations. Degree of conventionality or unconventionality should not be confused with degree of over-all adjustment, which was rated separately. Possible ratings ranged from highly conventional to highly unconventional. It was predicted that accident subjects would be rated as less conventional than nonaccident subjects.

7. *Over-all Adjustment.*—The degree of over-all adjustment—ability to live happily and function effectively—was rated by satisfactory resolution of subject's needs in relation to environmental and superego demands. This should be separate from conventionality or unconventionality of this adjustment. Possible ratings ranged from definitely disturbed to excellent adjustment. It was predicted that accident subjects as a group would tend to have a somewhat poorer adjustment than nonaccident subjects.

8. *Castration Anxiety.*—Possible ratings of specific evidence of castration anxiety, or generalized fear of injury to self, ranged from high to low, with a separate category entitled "Not clearly observable in these data." This variable was included largely because it appeared prominent in many of the psychological test reports. It was predicted, though without too much confidence, that nonaccident subjects would score higher on castration anxiety than accident subjects, the rationale being that high castration anxiety might make the subject more conscious of risk and less willing to engage in risk-taking behavior.

9. *Separation Anxiety.*—Possible ratings for separation anxiety (fear of loss of love and support, concern with oral supplies) ranged from high to low, with a separate category entitled "Not clearly observable in these data." As in the case of castration anxiety, this variable was included largely because it appeared prominently in many of the psychological test reports. It was predicted, again without too much confidence, that accident subjects would score higher on separation anxiety than nonaccident subjects, the rationale being that underlying feelings of lack of love lead to resentment which might tend to be acted out against figures perceived as depriving.

10. *Extent of Fantasy Preoccupation.*—Possible ratings ranged from excessive preoccupation with fantasy satisfactions through a mid-point of "effective integration of fantasy and action, planfulness" to extremely "stimulus-bound" (likely to act directly in response to people or objects with little fantasy or reflection). It was predicted that accident subjects would tend to cluster at the extremes, while nonaccident subjects would tend to fall around the midpoint.

11. *Character Type.*—Raters were asked to judge which of a number of character types most nearly described the subject (if more than one category was used, probable priority was indicated by using numbers 1, 2, etc.—see table 2). While it was not felt that this variable was likely to prove discriminating, it was included because of the attention it has received in the literature.

12. *Ability to Tolerate Various Tensions.*—Possible ratings of tolerance to tensions (i. e. without discharging them immediately) ranged from high to low, with a separate category entitled "Not clearly observable in these data." It was predicted that high-accident subjects would reveal a lower capacity for tension tolerance.

13. *Friendship Patterns.*—Finally, raters were asked to judge which of the following categories, in their opinion, most nearly described the status of the subject's social relationships: (*a*) no close friends, few casual friends; (*b*) some close friends, few casual friends; (*c*) some close friends, many casual friends; (*d*) no close friends, many casual friends. It

was predicted that nonaccident subjects would be more likely to fall into categories *b* or *c*, with accident subjects falling primarily in categories *a* or *d*.

Composite Individuals

In addition to the above variables, raters were presented with the following two personality-type descriptions, intended to characterize hypothetical composite nonaccident (type x) and accident (type y) subjects, and were asked to state which of the two types the subject most nearly resembled.

Type X.—The type x sort of person tends to be rather conventional in his values, attitudes, and behavior. In general, he seems to gain satisfaction for his needs from his everyday life and to have a fairly clear notion of the goals he wants to attain in life and of how to pursue them. He tends generally to have respect for the rights and opinions of other people, and in turn to be pretty well accepted by others. While he may be normally assertive in defending his own rights, he is seldom extremely demanding, domineering, or combative. In some cases, he may actually be somewhat less assertive than an adequate defense of his own rights would require. Such underlying hostility as he may have tends to be pretty well controlled and is seldom expressed in an obvious "acting-out" fashion. If psychopathology is present in this type, it is most likely to take the forms of denial, overly strong needs for conformity, castration anxiety and fear of aggression from others, and overly strong needs to please or placate others.

TABLE 1.—*Ratings of Clinical Psychological Reports for Accident-Repeater and Nonaccident Groups*

	Direction		Level of Significance (if Below 0.10)
Variable, No.	Accident	Nonaccident	
2 Hostility/control ratio	Less control	More control	0.02
3 Aggression and behavior	Aggressive	Adaptive, unassertive	0.05
5 Egocentric—balanced—sociocentric	Extremes	Balanced	0.01
9 Separation anxiety	High	Low	0.01
10 Fantasy—integration—stimulus-bound	Extremes	Integration	0.10
12 Tension tolerance	Low	High	0.01*
14 General personality	Type Y	Type X	0.10

* From psychiatric interview; all others from psychological reports.

Type Y.—While there may be a fair amount of individual variation on specific characteristics, in general the type y person tends to be rather unconventional in his opinions and values and sometimes in his overt behavior. He is inclined to be rather self-oriented, to have difficulty in relating easily and warmly to other people, and to be somewhat unaware of, or insensitive to their rights and feelings. He may in some cases feel that other people are difficult to understand. He often has feelings of dissatisfaction about his everyday life and is likely not to have clearly defined goals in life or consistent, practical methods for attaining such goals as he does have. He is apt to have difficulty in controlling his hostility, which may often be excessive, and consequently may at times be inclined toward overdetermined "acting-out" behavior, either at the level of overt physical belligerence or at the level of verbal aggression—in the form of sarcasm, carping complaints, or destructive comments. He is likely at times to exercise poor judgment in his evaluation of his environment or in choosing courses of action. In some cases, he may appear overly preoccupied with his own fantasy world and relatively cut-off from social relationships with others. If psychopathology exists in this type of individual, it appears most likely to take the forms of impulsive, hostilely-toned, acting-out behavior, poor reality testing, emotional lability, impaired intellectual functioning, a highly personalized, idiosyncratic fantasy, withdrawal from interpersonal relationships, or excessive immaturity.

Results

As may be seen from table 1, 6 of the 13 variables proved discriminating between high-accident and nonaccident subjects at the 0.10 level of confidence or better and 4 proved significant below the 0.02 level (i. e. less than 2 chances in 100 that differences this large or larger could have occurred by chance). Of the 11 variables hypothesized as possibly discriminating, 6 showed significant differences in the predicted direction, either in the psychological test battery, the psychiatric interview, or both.

In comparison with nonaccident subjects, the accident subjects showed a statistically significant tendency (1) to have less capacity for managing or controlling hostility; (2) to be either excessively self-centered and indifferent to the rights of others or excessively sociocentric (i. e. characterized by an "overdetermined" awareness of, interest in, and respect for the rights and feelings of others); (3) to be either excessively preoccupied with fantasy satisfactions or extremely "stimulus-bound"; (4) to be more fearful of loss of love and support (and, by inference, more angry and resentful toward persons viewed as depriving); and (5) to be generally less able to tolerate tension without discharging it immediately. In addition, the accident subjects tended to be categorized more frequently as consistently or occasionally belligerent or covertly hostile, and less frequently as only appropriately assertive, or unassertive. While not statistically significant, there were tendencies for the accident subjects to be rated as more conventional and generally better adjusted. There were no differences between accident and nonaccident subjects in ratings of reality orientation, castration anxiety, or friendship patterns.

Of the two variables hypothesized not to be discriminating, neither showed significant differences. Neither hostility alone, without reference to capacity for control, nor clinical character type showed any clear-cut trends. The distribution of accident and nonaccident subjects among the various character types is shown in table 2. Only subjects on whom both psychological test raters independently agreed are included in this comparison. Agreement was shown in 18 cases and disagreement in 2 cases. As may be seen, both accident and nonaccident subjects are distributed across a large number of categories, and there is little tendency for either accident or nonaccident subjects to concentrate in any particular category or categories. While the number of subjects in this study is too small to refute the hypothesis that certain clinical character types are more frequent among accident than nonaccident subjects, it seems clear that no single category could account for a majority of either accident or nonaccident subjects.

It will be noted that the predictive success of the clinical testing was considerably greater than that of the psychiatric interviews. While this fact may well reflect real differences in the predictive potential of the two measures, it should be pointed out that electronic recording difficulties resulted in incompleteness in a number of the interview transcripts, and this may well have lowered the predictive value of this measure.

It should also be observed that the present findings have not been cross-validated on other samples of subjects. This should certainly be done before the present results can be accepted without reservation. It may be that one or more of these findings will eventually prove to be the result of chance. However, it appears extremely unlikely that cross-validation will fail to support the main body of the findings, since it is extremely unlikely that significant differences would be obtained in 6 out of 11 cases by chance, especially with relatively small sample sizes.

The ratings of the two over-all personality-type descriptions resulted in correct discrimination of both accident and nonaccident subjects in 70% of the cases. Despite the small number of subjects, such a result would be expected by chance less than 10 times in 100. Thus, while a number of the specific variables rated had somewhat greater predictive value, in general it would appear that these personality-type descriptions provide a fairly adequate picture of the hypothetical composite accident and nonaccident individuals.

Objective Testing

In addition to the clinical studies described above, all subjects were administered a number of objective measures of interest, intelligence, psychophysical skills, and psychophysiological functioning. (Several of these measures, such as the Wechsler-Bellevue intelligence scale, were actually administered as part of the clinical studies, and analyzed clinically at that time, but the results of formal scoring will be considered here simply for expositional convenience.) Each of these measures will be discussed briefly, together with the results obtained.

The modified Allport-Vernon-Lindzey study of values measure, which had repeatedly proved discriminating in previous work on this project, was again administered. With use of the same formula (based on a combination of religious, theoretical, and esthetic scale scores) as in previous samples, 70% of subjects in the present group were correctly identified as accident or nonaccident type. This figure is significant at the 0.05 level of confidence and compares with discriminations of 73% in three previous samples.[2]

The Kuder preference record is basically a vocational interest test which yields measures of the extent of the individual's interest along 10 dimensions (outdoor, mechanical, computational, scientific, persuasive, artistic, literary, musical, social service, and clerical). The Kuder test was included in the present battery because previous results with the study of values suggested that other interest measures might also prove discriminating. As it turned out, most of the scales did not prove discriminating. However, a formula based on the computational and scientific scales (on which accident subjects were high) and the persuasive and clerical scales (on which nonaccident subjects were high), made it possible to identify 81% of subjects correctly as accident or nonaccident type. While this figure is significant at the 0.02 level, it cannot be accepted confidently until it has been cross-validated.

TABLE 2.—*Distribution of Character Type Ratings Among Accident-Repeater and Nonaccident Subjects*

	A*	N*		A	N
1 Hysteroid	0	1	8. Neurasthenic	0	0
2. Phobic	1	0	9. Paranoid	0	0
3. Obsessive	0	2	10. Psychopathic	1	0
4. Compulsive	1	0	11. Passive aggressive	2	2
5. Cycloid	0	0	12. Passive dependent	1	1
6. Schizoid	1	3	13. Aggressive reaction	1	0
7. Anxiety state	0	0	14. Intellect disorder	1	0

* A = accident repeater; N = nonaccident.

The American transit motor abilities test, developed by Kraft and his associates [3] in their studies of bus drivers, is intended as a measure of driving aptitude. The subject is seated at the wheel of a mock-up bus and, in response to visual light patterns on a board across the room, is required to carry out various maneuvers with brake, steering wheel, gearshift, and clutch. All responses are recorded electrically. In this situation, accident subjects reacted more quickly and took less time to complete the task but made more errors than nonaccident subjects. All measures were significant at the 0.05 level of confidence or better.

All subjects were examined for psychophysiological responsiveness, under both resting and stress conditions (i. e., before, during, and after presentation of an incomplete sentences test containing both emotionally charged and neutral topics). The scores obtained included measures of respiration, muscle tension, psychogalvanic skin reflex, heart rate, and a combined measure of over-all reactivity. While wide individual differences occurred among subjects in their psychophysiological responsiveness on all measures, none of the measures proved discriminating between accident and nonaccident subjects, although there was some tendency for the accident group to have a slightly faster heart rate during presentation of the test.

TABLE 3.—*Intelligence Test Scores of Accident-Repeater and Nonaccident Groups*

	Means	
	A*	N*
1. Wechsler adult intelligence scale		
Prorated intelligence quotient	105.3	106.3
Weighted subtest scores		
Information	10.6	10.2
Comprehension	11.9	12.0
Similarities	10.6	11.4
Block design	11.4	11.9
2. Shipley-Hartford vocabulary score	27.8	25.9

* A = accident-repeater; N = nonaccident.

All subjects were administered two measures of intelligence, a portion of the Wechsler-Bellevue adult intelligence scale (four subtests), and the Shipley-Hartford vocabulary scale. As may be seen from table 3, no significant differences between the accident and nonaccident subjects were obtained on any of these measures. Thus, it would appear that the differences between accident and nonaccident groups which were found on other measures could not be attributed to differences in the over-all intellectual level of the two groups.

In previous phases of this research,[2] subjects were administered the Minnesota multiphasic personality inventory (MMPI) and a social history questionnaire. While neither of these measures as a whole proved helpful, item analysis yielded a number of items which in themselves appeared promising but which required cross-validation before they could be confidently accepted. For this reason, these items were repeated with the present sample of subjects. These items and their level of significance in the 1955 and 1956 samples, as well as in the current study, are shown in table 4. As may be seen, very few of these items continue to prove discriminating with repeated testing. The overwhelmingly negative character of these findings, particularly on the MMPI, appears especially interesting, since these findings conflict with those of other investigators on somewhat similar samples of subjects.[4]

The Rorschach and the thematic apperception test (TAT), which had been individually administered to each subject during the clinical phase of this study and interpreted clinically at that time, were later scored objectively for a number of differentiating characteristics derived from previous samples.[2] The accident and nonaccident groups were compared across scores for these characteristics. On both the Rorschach and TAT scores, the differences between the accident and nonaccident groups were not sufficiently pronounced to meet the 0.10 level of statistical significance required.

Comment

While previous research on the present project demonstrated that the accident-repeater and nonaccident airmen differed significantly from one another, and while certain isolated psychological measures proved highly predictive of accident status for this population, the psychological significance of these measures was difficult to interpret. It was felt that further research was necessary before a clearer understanding of the psychodynamic relationships existing between the structure and functioning of the individual and his accident susceptibility could be achieved.

The primary aim of the present study, therefore, was to obtain a broader knowledge of the characteristics of accident and nonaccident subjects. Twenty representative high-accident and nonaccident rate airmen were studied intensively, using individual clinical psychological and psychiatric techniques, as well as a number of measures of interest, intelligence, psychophysical skills, and psychophysiological functioning.

TABLE 4.—*Summary of Significant Differences Between Accident-Repeater and Nonaccident Groups on MMPI* and Social History Items*

Item	High	1955	1956	1957
MMPI*				
Go to church almost every week	N†	0.05	0.20	ns‡
Never did anything dangerous just for the thrill of it	N	0.20	0.20	ns
Frequently notice hand shaking when trying to do something	N	0.20	0.20	0.20
Used alcohol excessively	A	0.10	0.20	ns
Never been in trouble with the law	N	0.20	0.05	ns
When with a woman a man usually thinks about things related to her sex	A	0.01	0.20	ns
Pray several times a week	N	0.20	0.01	ns
Social history				
Single versus married	N	ns	0.10	0.20
No. of brothers	N	0.01	0.10	0.05
Drink to relax	A	...	0.20	0.10
Father attends church	N	0.10	0.01	ns
Desires to run away from home	A	0.01	0.20	0.10
Have ever been arrested (independent of traffic violations)	A	0.01	ns	ns

* MMPI = Minnesota Multiphasic Personality Inventory.
† N = Nonaccident; A = Accident repeater.
‡ Not significant below 0.20 level.

It is felt that the positive findings of the present study, particularly in the clinical area, contribute materially to a clearer understanding of the relation of psychological factors to accident susceptibility, at least in the population of airmen from which these samples were drawn.

4200 E. Ninth Ave. (20) (Dr. Conger).

This investigation was conducted under the auspices of the Commission on Accidental Trauma of the Armed Forces

Epidemiological Board and was supported by a research contract with the Office of the Surgeon General, Department of the Army.

ALCOHOL IN THE SINGLE VEHICLE FATAL ACCIDENT

EXPERIENCE OF WESTCHESTER COUNTY, NEW YORK

William Haddon Jr., M.D., M.P.H., Albany, N. Y.
and
Victoria A. Bradess, M.D., Valhalla, N. Y.

Records of motor vehicle accidents occurring over an eight-year period were used for the identification of all drivers killed in accidents involving neither other vehicles nor pedestrians. The resulting group of 117 drivers included 87 who died within four hours of their accidents. Postmortem determinations for alcohol were performed in 83 (95%) of these 87 cases. Of these 83, forty-one (49%) were found to have had blood alcohol levels of 0.15% or more at death; and an additional 17 (20%) were found to have levels between 0.05 and 0.15%. There is justification for assuming that any driver with a blood alcohol level of 0.15% or more is incapable of driving safely and that this is also true of many drivers with levels in the 0.05 to 0.15% range. It is therefore concluded that the use of alcohol was probably a causal factor in one half or more of the deaths which resulted from accidents of this type.

Estimates of the frequency of markedly elevated blood alcohol levels among those involved in motor vehicle accidents have ranged from 10 to 80%.[1] It is the purpose of this paper to report the findings of an exploratory investigation designed to quantitate more precisely this factor in a specific group of fatalities occurring in one area and to suggest that similar groups may prove useful for statistical purposes.

Most reports of the frequencies of such postmortem alcohol levels, a number of which have recently been summarized by Plymat,[2] have come from police and related sources. In general, with relatively few exceptions, these have failed both to reach the available scientific literature and to be presented in a sufficiently documented form to permit their complete evaluation from the scientific standpoint. Their value, as a result, is difficult to assess. Taken as a group, however, one or more of a number of substantial shortcomings appear to have been present in many instances. Foremost among these has been the frequent study of only relatively small fractions of the groups of fatalities whose characteristics these fractions were assumed to represent. Furthermore, it has been a not uncommon practice to group the persons killed without reference to their individual responsibilities for the collisions in which they were involved. In addition, some investigators have studied subjects who have died as long as 24 hours after the time of the accident, a procedure which has undoubtedly resulted in the inclusion of some whose original blood alcohol levels had undergone substantial metabolic lowering in the relatively long interval prior to death. Finally, information has often been omitted both as to the biological materials on which the determinations were based and as to the circumstances of their collection.

From the Driver Research Center of the New York State Department of Health and the New York State Bureau of Motor Vehicles, and the Office of the Medical Examiner, Westchester County.

Read in the Session on Traffic Accidents before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

In order to avoid these and related deficiencies, the retrospective and exploratory investigation reported here sought, as its primary objective, to determine the levels of alcohol present in the blood of a carefully studied group of drivers, those whose fatal accidents had involved neither pedestrians nor vehicles other than their own and who had survived for not more than a given short period after the event.

Case Material

The group which provided the subdivision used consisted of all motor vehicle fatalities which had occurred in Westchester County from Jan. 1, 1950, through Dec. 31, 1957. To assure completeness, the files of the Office of Vital Statistics in the New York State Department of Health were used to identify all deaths due to motor vehicle accidents in Westchester County during that period. The resultant lists were matched with those of the Office of the Medical Examiner. Of the 626 cases identified in this fashion, 37 were excluded. These consisted of 20 driveway and other off-highway motor vehicle fatalities and 17 borderline cases which, though they had occurred upon public roads more or less in association with motor vehicles, were not considered appropriate for inclusion. Illustrative of the latter group were such cases as those of a single pedestrian suicide and of two persons who fell after alighting from unmoving vehicles. The remaining 589 fatalities formed the basis of the present study.

Table 1.—*Classification of Motor Vehicle Fatalities by Age of Person and Type of Specimen Used for Alcohol Level Determination, Westchester County, New York, 1950-1957*

		Age 16 Years and Over					
			With Alcohol Level Determination		Specimen Used		
Class of Fatality	Total All Ages	Total	No.	%	Blood	Brain	Liver
Drivers	208	208	160	77	124	7	29
Single motor vehicle	117	117	95	81	76	4	15
More than one motor vehicle	84	84	58	69	44	3	11
Other and not specified	7	7	7	*	4	...	3
Passengers	197	184	107	58	97	1	9
Pedestrians	177	136	78	57	60	4	14
Others	7	1	0	*	...	...	...
Total	589	529	345	65	281	12	52

* Percentages based on less than 10 observations are not indicated.

Westchester, a wealthy county of 435 square miles located immediately north of New York City, includes urban, suburban, and semirural areas. According to the 1957 special census its population was 752,406, an increase of 126,590 over 1950. Although data are not available as to the number of residents holding driver's licenses, registrations of vehicles of all types are known to have increased during the same period from 213,000 to 308,000. No appreciable information was available either as to the number of miles driven within the county or as to the ways in which vehicles were used, although it is known that much of the traffic load is produced by nonresidents.

Alcohol Determinations

Of the 589 fatally injured persons, 345 (65%) had had alcohol determinations (table 1). Two hundred eighty-one of these were based on blood, 12 on brain, and 52 on liver specimens. These determinations were made with a modification of the Jetter method,[3] a procedure which measures volatile reducing substances, here taken as ethanol. Blood specimens consisted of heart blood drawn at autopsy, in almost all cases prior to the severance of the great vessels. No femoral or other peripheral blood specimens were used. In the several instances in which brain and liver alcohol levels were determined, parenchymal tissue was used. The values given for all specimens are the results of the laboratory determinations, although it is known that brain and liver alcohol levels tend to be substantially lower than the simultaneous blood concentrations.[4] For this reason, the group of liver and brain alcohol values given here may be regarded as a conservative estimate of the blood alcohol levels to which they corresponded.

As noted, postmortem alcohol determinations had been carried out in only a fraction of cases, and only rarely among those under 16 years of age. However, even when limited to those 16 years of age and over, determinations were found to have been performed in the latter group least often for pedestrians (57%) and passengers (58%) and most often for drivers (77%). As a result of the relatively large percentages of these groups lacking determinations, it was not felt that estimates of the distributions of alcohol levels among their numbers could be made without further subdivision.

Results

The total group of 589 motor vehicle fatalities was first analyzed in order to determine whether or not there had been any significant changes over the eight years represented. The variations in the total number of fatalities from year to year proved not to be statistically significant ($p>0.10$). In addition, the variations from year to year by type of accident, class of vehicle involved, class of fatality, and age or sex of the deceased all proved to be not statistically significant ($p>0.10$).

The data for the eight-year period were therefore combined and treated as a single group. When handled in this fashion, there was no statistical significance in the variation in the number of fatalities from month to month ($p>0.70$). However, as anticipated from many prior reports, many more fatalities occurred during the two and one-half day period between 5 p. m. Friday and 5 a. m. Monday than during the remainder of the week. This is seen in the fact that 277 (48%) of the 573 fatalities for which complete information was available with regard to time and day of accident fell in this 60-hour week-end period. In addition, when distributed by time of day, it was found that 63% of the 573 fatalities resulted from accidents which occurred between 5 p. m. and 5 a. m.

Table 2.—*Blood Alcohol Level and Interval Between Accident and Death for Fatally Injured Persons Sixteen Years of Age and Over, with Blood Alcohol Level Determinations, Westchester County, New York, 1950-1957*

Alcohol Level, % by Weight	Total	Interval Between Accident and Death, Hr. <4	4-11	>11	Not Specified
Negative	147	117	21	9	...
0.01-0.04	13	10	2	1	...
0.05-0.09	23	19	3	...	1
0.10-0.14	15	15	...	...	...
>0.14	83	79	3	. .	1
Total	281	240	29	10	2

As has been noted, alcohol levels were not determined for all fatally injured persons. Since the minimum licensing age in New York is 16, and since alcohol determinations were rarely carried out on children, the data given in tables 2 and 3 were restricted to include only fatally injured persons 16 years of age and over. From table 1, it is noted that this restriction did not reduce the number of drivers used in this study, since not one of the 208 drivers in the total group of 589 fatalities was under 16.

In order to avoid the reporting of postmortem alcohol levels which had been subject to substantial metabolic lowering during the period between accident and death, it was decided to consider only those persons who had died within four hours of their accidents. Table 2 indicates the effect of this restriction on the composition of the group retained for study purposes.

It was initially believed that the study of those drivers who had had alcohol determinations would make possible the ascertainment of whether or not the levels found in heart blood might have been influenced by diffusion of alcohol from the viscera. Since it was reasonably expected that the presence and magnitude of this possible artifact would be a function of the interval between death and the drawing of the specimen at autopsy, the levels were grouped according to the time which had elapsed before the collection of each individual specimen. In doing this it was observed that most of the cases with the longer intervals between death and postmortem examination were those of individuals who, in being killed as the result of evening and early morning accidents, had not had autopsy performed until the next working day. As a result, the group whose examinations had been most delayed was heavily weighted with cases from that period of day in which a higher percentage of drivers had been drinking and in which relatively higher alcohol levels were present. Because of this selection, it was not possible to demonstrate the presence or absence of an artifact of this type, the possible significance of which is discussed below.

During the eight years studied, 87 single vehicle accidents occurred which involved neither pedestrians nor other vehicles and as the result of which the driver in each case died within four hours of the accident. It will be recalled that it was the description of the blood alcohol levels of this group which constituted the primary objective of this investigation. Fortunately, because of a long-standing interest of the Office of the Medical Examiner [5] in the extent to which alcohol was present among driver fatalities, 83 (95%) of this group had had alcohol level determinations. The resultant data are presented in table 3.

The results given in table 3 show that 41 of the 83 "single vehicle" drivers examined possessed blood alcohol levels of 0.15% or more at the time of death. These constituted 49% of the group. The levels of an additional 17 of this group (20%) fell between 0.05 and 0.15%. In comparison only 22 (27%) were negative. It is noted that the 83 drivers included 7 truck operators, all men, and 6 women operators of passenger automobiles. Of these, one of the former and three of the latter had levels of 0.15% or higher.

Previous Research

The improper use of alcohol as a cause of motor vehicle accidents has been repeatedly reported from many regions of the earth, including Canada, Scandinavia, Germany, France, Italy, the United Kingdom, South Africa, Australia, and the United States. (The *Quarterly Journal of Studies on Alcohol* contains abstracts of technical papers concerned with alcohol, including, in particular, many dealing with motor vehicle accidents.) In view of this, it is remarkable neither that much basic research has been completed nor that much remains to be done.

Table 3.—*Alcohol Level by Type of Specimen in Eighty-seven Drivers Involved in Single Vehicle Accidents Who Died Within Four Hours of Accident, Westchester County, New York, 1950-1957*

Total	87	22	3	11	6	41	4

* Values shown are actual results of laboratory determinations. Values for brain and liver specimens have not been adjusted for known differences between tissue and blood levels (see text).

In general, research dealing with this problem has largely fallen into two categories: (1) the determination of the extent to which accident liabilities increase in association with blood alcohol level and (2) the determination of the extent to which individuals with such elevated levels are responsible for accidents. Although the present paper is concerned with the second of these research areas, it is appropriate to indicate briefly the findings of the first and to suggest sources of additional information.

Thus, for example, Loomis and West[6] in a recent study with use of "a simulated automobile driving apparatus . . . to evaluate the effect of alcohol as it pertains to several functions involved in driving an automobile," have demonstrated "a direct relationship between the blood alcohol concentration and the extent of impairment of function." Furthermore, these workers found that (1) all of the eight subjects (apparently none of them heavy drinkers) who were tested when their blood alcohol levels were "at or above 0.05% showed some impairment as compared to their control performance," (2) the two subjects who were tested when their blood alcohol concentrations were 0.03% showed performance below control values, and (3) "in the presence of a blood alcohol concentration of 0.15 per cent performance had decreased to approximately two-thirds of the control values."[7]

Other workers, notably Coldwell and others, in "Report on Impaired Driving Tests,"[1] and Bjerner and Goldberg,[8] used objectively scored driving tests given to subjects before and after the use of beverage alcohol. In the most recent of these,[1] 50 adult male subjects, including 5 who "habitually consumed, each day, alcoholic beverages equivalent to at least 6 fl. oz. of distilled spirits" and 5 who "consumed twice this quantity daily," repeatedly drove through a standardized test. The many results of this investigation included (1) the finding of one individual whose performance was impaired at a venous blood alcohol level of 0.04%, (2) the demonstration that one-half of the 50 subjects showed objective impairment of driving ability at a venous blood alcohol concentration of 0.08%, and (3) the finding that all subjects exhibited some evidence of impairment at levels less than 0.15%. The authors pointed out that the men were in a competitive situation which placed a premium on optimum performance and that the test was relatively simple, presenting neither the emergencies nor other hazards present in normal driving.

Two additional studies require mention. In the first of these,[9] by the comparison of the blood alcohol levels of 433 drivers involved in accidents with those of 2,015 driver passers-by, three conclusions were reached: "1. The hazard is significant when the blood alcohol concentration is above 0.10%. 2. In the range 0.10-0.15% blood alcohol concentration, the hazard of accident is two and one-half times that when the concentration of alcohol in the blood is less than 0.05%. 3. This hazard of accident when blood concentrations are above 0.15% is approximately 10" (i. e., there were 10 times as many drivers with levels of 0.15% and above in the accident-involved group as in the control group of uninvolved drivers). The second study,[10] through the use of samples obtained from 542 of 919 drivers involved in personal injury accidents, compared the blood levels of those rated highly responsible for the accidents in which they were involved with the levels of those rated as either not responsible or only slightly so and demonstrated an increasing statistical excess of accident-responsible drivers which first became significant in the 0.03 to 0.05% range. Additional research[11] conducted in Sweden, with appropriate controls, has shown that chronic alcoholics and other alcohol abusers were heavily overrepresented in a consecutive series of 2,100 persons convicted of drunken driving.

We do not intend to imply by the title and content of the present paper that we regard the presence of alcohol as the only pertinent characteristic of the individuals described. It might be expected, in fact, that other personal characteristics, themselves associated with individual drinking patterns, would also be related to accident liability. The results of another well-controlled Swedish investigation are of some interest in this connection, however. This study[12] of 71 hospitalized traffic victims showed that, although heavy users of alcohol were highly overrepresented among casualties who had been drinking, they were not overrepresented among those casualties who had not been drinking. These results suggest that the changed liability which the heavy user group exhibited was very closely associated with, if not directly caused by, the use of alcohol.

Medicolegal Interpretations of Blood Alcohol Levels

In the United States, the Uniform Vehicle Code, Model Chemical Test Law, used (July 1, 1957) in 27 of the 48 states,[13] defines (Article IX, Section 11-902) the following presumptions: 1. If there was at that time 0.05% or less by weight of alcohol in the defendant's blood, it shall be presumed that the defendant was not under the influence of intoxicating liquor. 2. If there was at that time in excess of 0.05% but less than 0.15% by weight of alcohol in the defendant's blood, such fact shall not give rise to any presumption that the defendant was or was not under the influence of intoxicating liquor, but such fact may be considered with other competent evidence in determining the guilt or innocence of the defendant. 3. If there was at that time 0.15% or more, by weight, of alcohol in the defendant's blood, it shall be presumed that the defendant was under the influence of intoxicating liquor. (Although there is much individual variation, and although many factors influence the rate of absorption of alcohol and the levels achieved, it is commonly stated that "In order to obtain a blood alcohol level of 0.05% a 150-lb. (68-kg.) person would have to accumulate 1 fluid oz. (30 cc.) of pure alcohol in his body. To do this he would have to drink at least the equivalent of 2 oz. of 100 proof liquor. This same person would have to accumulate 3 oz. of absolute alcohol to reach a blood alcohol level of 0.15%." [14]) 4. The foregoing provisions shall not be construed as limiting the introduction of any other competent evidence bearing upon the question whether or not the defendant was under the influence of intoxicating liquor.

This corresponds to the position of the American Medical Association, which has long endorsed the same limits, "limits (which) were purposely made liberal so that no injustice would be done to the person with unusual tolerance." [15] Nevertheless, proposals for a lowering of the 0.15% limit to 0.05% have been made.[16] It is pertinent, in this respect, that at a 1952 "meeting of Scandinavian criminologists held in Copenhagen . . . the representative of Norway (which has long enforced the 0.05 per cent limit) . . . criticized the Norwegian . . . limit very strongly" on the grounds that it placed undue emphasis on "a chemical determination." The latter position was not supported, however, by "other Norwegian members of the conference." [17]

Significance of Data

With the foregoing findings as background, it was not considered necessary to prove again that the use of alcohol is a causal factor in some motor vehicle accidents. Furthermore, it was not considered necessary to demonstrate once more that there are substantial differences between the distributions of the alcohol levels among accident-involved drivers and those of the driving populations from which they come. It was the purpose, therefore, of the investigation reported here to determine the extent to which individuals with levels already demonstrated to be associated with markedly increased liabilities were present in a group of drivers killed in single vehicle accidents without pedestrian involvement. Fatally injured persons of this type constitute the only group of persons on whom autopsy is performed who may be regarded without additional evidence as having been responsible in most cases for the accidents which cause their deaths. This group offers, as a result, opportunities for study which are not present when pedestrian and multivehicle accidents are considered, since information concerning the principals (i. e., all involved drivers and pedestrians) in, and circumstances of, such events is seldom complete. It also requires neither the personnel nor the expenditures which are required for the collection and analysis of specimens from the principles involved in the more complex varieties of accidents.

An additional reason for choosing one accident type stems from the increasing tendency in this field to compare the alcohol levels found among accident-involved drivers and pedestrians in different communities and jurisdictions. Unfortunately, such comparisons have frequently grouped together dissimilar types of accidents and, in addition, have compared groups of data weighted with those particular combinations of accidents most common in each area considered. If such inevitable comparisons are to be made, it would appear essential that, whenever possible, they be based on the use of careful breakdowns into similar accident categories, since it would be expected that the causes of accidents might vary considerably from one type to another. It is suggested, therefore, that the alcohol levels found in drivers in the "single vehicle group," as used and defined in this paper, may serve as the basis of one form of comparison between jurisdictions which have sufficient fatalities to allow their subdivision to this extent.

This proposal for the use of comparisons based on the levels found in this group is based, as has been noted, on a number of practical limitations in the extent to which inferences may be founded on examinations of motor vehicle fatalities. As such, it too has limitations. The first of these results from the fact that knowledge in this field is so incomplete that it is at present seldom possible to extrapolate quantitatively from fatal to nonfatal accidents or the reverse, a point which is commonly overlooked. In addition, quantitative extrapolations from the single vehicle group to pedestrian and multivehicle accidents must also await the results of additional research dealing with these groups, although it is well known that many of the multivehicle and pedestrian accidents which have occurred in Westchester and elsewhere have been caused by drivers and pedestrians who were drunk at the time.

It should be noted in this context, however, that related information has long been available concerning the experience of one community, Uniontown, Pa., with another group of drivers presumably responsible for the accidents in which they were involved. Thus, Heise found, in a pioneering investigation reported in 1934, that the alcohol levels of a consecutive series of six apprehended "hit and run" drivers fell between 0.21 and 0.38%, the mean value being 0.30%. By contrast, on the basis of 119 consecutive accidents, he also concluded with respect to pedestrian accidents that "the drivers who struck children or old people were in most cases sober," and that "the largest number of accidents in this group . . . [involved] the drinking pedestrian." [18] This again suggests the need for the careful separation of accidents into discrete categories and the caution which should be used in attempting extrapolations from one group to another.

The limitation of the present series to those dying within four hours of their accidents was based on a compromise between the relatively rapid rate at which alcohol is known to be metabolized [10] and the need for including as many cases as possible in order to facilitate their analysis. In recognizing that the levels in many individual cases have been shown to remain elevated for much longer periods after ingestion than this,[19] it must nonetheless be remembered that many of those killed may well have already been on the descending slopes of their blood alcohol curves at the times of their accidents. For this reason, the four-hour interval is believed to represent a conservative compromise, one that is also supported by the fact that the levels found among those who had died between 4 and 12 hours after their accidents tended to be lower than those found among persons who had died in a shorter time. It is of further interest that 219 of those listed in table 2 had died within two hours and 199 within one hour of their accidents, a point which also has significance from the standpoint of the organization and emphasis of emergency medical care.

It has been mentioned that heart blood had served as the basis for most of the alcohol determinations on which this study was based and that no femoral or other peripheral specimens had been used. This point is emphasized because of the considerable literature dealing with the meaning and relationships of alcohol levels as determined from various portions of the cardiovascular system.[20] Thus, it has long been known that during the stage of active absorption of alcohol from the gastrointestinal tract the levels present in the venous return from the limbs may be considerably lower than those found in blood drawn from the heart, a difference which is attributed to the comparatively long time required for the levels in the relatively avascular tissues of the extremities to come into equilibrium with those of the arterial blood.[4] In addition, Gifford and Turkel have demonstrated in a series of 11 cases that whiskey introduced into the stomachs of nonalcoholic cadavers on which autopsy was performed 10½ to 24 hours later consistently produced alcohol levels in heart blood. This suggested that similar false elevations might occur in the heart blood of fatally injured persons whose viscera contained high concentrations of alcohol as the result of the use of alcoholic beverages shortly before death. Since these workers also demonstrated in this series that diffusion into the femoral blood was negligible, it became possible for them to compare individual postmortem heart and femoral alcohol levels in an investigation of the extent to which such an artifact might be present in actual practice. This was done in a series of 51 alcoholic cadavers. The results indicated that the discrepancy sought might prove of considerable medicolegal importance in occasional cases. It was also demonstrated, however, that the average excess of the heart blood alcohol level over that found in the femoral vein was slightly less than 0.01%.[20b] In view of the latter finding, it is considered improbable that such a diffusion artifact had to any appreciable extent influenced the alcohol levels given in the present report.

The results of the investigation reported here show that at the time of death 49% of the drivers killed in single vehicle, nonpedestrian accidents possessed blood alcohol levels of 0.15% or more by weight. These levels are widely accepted on the basis of a considerable body of scientific knowledge as presumptive evidence of drunken driving. An additional 20% of the drivers in this group possessed levels between 0.05 and 0.15%. As discussed above, it has been shown that many persons with levels in this range not only exhibit measurable deteriorations in driving performance but also are overrepresented in accident groups.

In view of these findings from Westchester County, it is appropriate to question the extent to which similarly elevated levels might be found elsewhere in fatally injured persons of this type. Fortunately, one set of data already existed which was indicative of the somewhat comparable experience of another section of the United States. Thus, the Delaware State Police have studied all fatal accidents occurring each year at locations outside of the city of Wilmington, with particular reference to the alcohol levels of most principals. As a result it has been possible, on the basis of data made available to us through the courtesy of the Delaware authorities,[21] to identify a group of fatally injured drivers similar to the single vehicle drivers studied in this report. This group consists of the 15 fatally injured drivers during 1957 whose passenger automobile accidents involved neither pedestrians nor other vehicles and who were listed as having died either at the scene of the accident or prior to arrival at the hospitals to which they were taken. Ten (67%) of this group were found to have blood alcohol levels of 0.15% or more, and two had levels between 0.10 and 0.15%. These data suggest that the high alcohol levels observed among drivers killed in single vehicle accidents in Westchester County may exist in other sections of the United States.

In conclusion, it is recalled that Heise stated in 1934 "that the problem of controlling the drinking driver and pedestrian is far from being solved may be due, in part, to the fact that no accurate statistics are available regarding the relationship of alcohol to automobile accidents. . . ."[18] On the basis of the findings presented in this report and previous work in this field, it appears highly probable that the use of alcohol was a causal factor in the deaths of one-half or more of the drivers killed in the single vehicle accidents which occurred in Westchester County over an eight-year period.

Summary

The postmortem blood alcohol levels were studied in a group of 83 drivers whose fatal accidents involved neither pedestrians nor other vehicles and whose deaths followed within four hours.

Forty-nine per cent of the 83 were found to have had blood alcohol levels of 0.15% or more at death, while those of an additional 20% fell between 0.05 and 0.15%. From this and previous studies it is concluded that it appears highly probable that the use of alcohol was a causal factor in the deaths of one-half or more of the drivers killed in the single vehicle accidents which occurred in a suburban county over an eight-year period.

84 Holland Ave. (8) (Dr. Haddon).

The authors wish to express their appreciation to Mr. Andrew Frey and Mr. Morton Berk for performing the many chemical analyses on which this report is based. They also wish to thank Mrs. Helen C. Chase and the staffs of the Driver Research Center and the Office of the Medical Examiner for their most generous assistance.

CARBON DIOXIDE POISONING.—Although rarely reported, carbon dioxide poisoning is probably not so infrequent an occurrence. . . . Early in March, 1956, a liner arrived at Penang with a cargo of onions. The particular hold had been loaded six days previously, and contained 5,000 bags of onions and a quantity of . . . a crude brown sugar obtained from the sap of palm trees. It was full to within 9 ft. (2.7 m.) of the deck. At about 1 p. m. the ship was boarded by labourers, who removed the hatch covers and opened the hatch. One entered the hold and collapsed as he was standing on the onions. Another went in to help him and also collapsed. Then the ship's doctor was sent for; he went into the hold, followed by one of the ship's officers, and assisted him to lift the unconscious man who had first entered the hold. As he was doing so the doctor collapsed, and the ship's officer carried the man out. One of the ship's crew then went into the hold to assist, but he collapsed. Another ship's officer then entered with breathing apparatus, and brought out the doctor and the other unconscious men. The four men who had collapsed were then taken to hospital, where it was found that two of them were dead. Four other labourers who had also entered the hold for short periods developed minor symptoms and were taken to hospital. . . . An analysis of the gases present in the hold was carried out by the senior chemist about an hour and a half after the hold had been opened. He obtained an appreciable reaction for carbon dioxide in the hold, particularly beneath the deck; and on examining other holds in the ship, as yet unopened, he obtained a strong reaction. No other poisonous gases were detected.—H. I. Williams, M.D., B.Chir., Carbon Dioxide Poisoning, *British Medical Journal,* Oct. 25, 1958.

POSTERIOR COLPOTOMY INCISIONS IN GYNECOLOGIC DISEASE

Raphael B. Durfee, M.D., Portland, Ore.

Posterior colpotomy has the advantage over culdoscopy and colpocentesis in that it gives much more diagnostic information. It is safer than anterior colpotomy, which has to be done with special care to avoid the bladder, ureters, and perivesical venous plexuses. Moreover, by extension of the incision after diagnosis and using proper retraction, considerable pelvic surgery can be accomplished. Colpotomy was carried out in 94 women, the most frequent indication being ovarian cyst (29 cases). In the technique which is described, a posterior incision was used in all but two cases. The most frequent findings were ovarian cyst (34 cases) and pelvic inflammatory disease (17). Recovery was uncomplicated in 84 cases; five patients had postoperative complications and five others subsequently underwent laparotomy. The results justified the procedure, which is less traumatic than exploratory laparotomy and can be used in many situations in which an exploratory laparotomy is not really indicated.

With the increased interest in vaginal hysterectomy and vaginal surgery in general in the past 25 years, the use of a posterior, and occasionally an anterior, incision of the vaginal wall for exploration of the pelvis should be more widely known and practiced. Posterior colpotomy has been disregarded for many years as either a diagnostic or a therapeutic measure in gynecology. The literature of 50 or 60 years ago contains numerous papers on this subject. The primary reason for the disuse of the procedure has been the increasing safety of an anterior abdominal wall incision. Such an incision provides maximum exposure in the pelvis, and it is this improvement in exposure and the allowance for wider surgical performance that has led to the abandonment of colpotomy as a popular procedure. Posterior cul-de-sac puncture (colpocentesis) and culdoscopy have, however, enjoyed some measure of interest in recent years, and in view of modern medical economics, improved techniques in anesthesia, and the generalized use of antibiotics it is important to reconsider the use of colpotomy incisions in gynecologic diagnosis and therapy.

The term colpotomy covers three procedures. In the first, puncture colpotomy, a needle or trocar is used in the posterior cul-de-sac for intraperitoneal aspiration. This is in reality a colpocentesis. The second is a small posterior cul-de-sac incision for the intraperitoneal insertion of the culdoscope. The third is a wide incision (3 to 6 cm.) penetration of the posterior cul-de-sac into the peritoneal cavity. This can be accomplished anteriorly under the bladder but with greater difficulty.

The advent of the culdoscope has made possible the use of the posterior cul-de-sac as an avenue of exploration for diagnosis in the pelvis. This is primarily a diagnostic instrument, although Decker has reported using it for ovarian biopsy and the collection of an ovum at the time of ovulation.[1] While culdoscopy is a great improvement over colpocentesis, it entails the added difficulty of proper positioning of the patient for adequate examination. This is no easy task in many instances. Also, the reversal of the normal position of the pelvic organs, as seen through the culdoscope, occasionally gives a distorted pathological impression, and the magnification of the lenses of the instrument often gives a false interpretation of the pelvic findings. It is, however, a fine diagnostic tool, and its use is more feasible for diagnostic procedures in the pelvis generally than colpocentesis. Culdoscopy has been carried out in office practice, but this is not recommended.

Diagnostic information obtained by colpocentesis is much more limited. By this method different kinds of fluid from the abdominal cavity can be obtained through a needle or trocar. This is a very confined diagnostic medium and, in fact, is often unreliable. The dangers inherent in blind puncture of the cul-de-sac and the undependability of findings have led to the condemnation of the method by many gynecologists. The primary therapeutic use of colpocentesis is drainage of a cul-de-sac abscess. The number of procedures that can be accomplished through either a posterior or anterior colpotomy approach is far greater than that possible with either colpocentesis or culdoscopy.

Methods

There are two types of difficulty that may arise in connection with colpotomy: preexisting factors rendering exposure difficult, and surgical complications. Among the anatomic causes of preexisting difficulty are obesity; contracted vagina (long, narrow, small, and senile); virginal inlet; nulliparous inlet; and pregnancy. Pathological causes of pre-

---

Read before the Section on Obstetrics and Gynecology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

existing difficulty include pelvic adhesions (pelvic inflammatory disease or endometriosis); pelvic carcinoma; uterine and cervical myomas; intestinal tumors; and solid ovarian tumors. Possible intraoperative surgical complications include perforation of the intestine (usually of the rectum); spillage of intestinal contents; ovarian cysts (dermoid or malignant); hemorrhage; and, with anterior colpotomy, injury to the urinary tract. Possible postoperative complications include intraperitoneal and extraperitoneal hemorrhage; vaginal cuff hematoma; infection; and painful vaginal scar.

In general, contraindications to colpotomy include severe chronic pelvic inflammatory disease; extensive intra-abdominal adhesions; endometriosis; ruptured ectopic pregnancy (with patient in shock); large intra-abdominal tumors; known ovarian carcinoma; and cases in which the cul-de-sac is not obviously free.

Ninety-four patients were subjected to colpotomy. A listing of the procedures accomplished follows. These patients came from private practice, the U. S. Army Medical Service, and the University of Oregon Medical School Hospitals and Clinics. The method was adopted in order to evaluate its applicability to modern approaches in gynecologic diagnosis and treatment. Certain observations were proposed in order to do this. The technique used was a simple one, similar to that of Bradbury.[2]

Technique.—With the patient in position as for lithotomy, the posterior cul-de-sac is identified and traction put on the vaginal mucosa with an Allis tissue forceps placed near the cervix, which is also on traction (fig. 1). A transverse incision from 3 to 6 cm. in length is made in the vaginal mucous membrane (fig. 2), the peritoneum is identified and entered (fig. 3 and 4), and the lip of the posterior retractor is placed in the peritoneal opening, which may be retracted anteriorly with use of a Deaver retractor. The uterus is then retroflexed for better exposure when necessary. On conclusion of the pelvic exploration or surgery, the peritoneum is closed (fig. 5) with a purse-string suture of fine chromic catgut. The vagina is then closed (fig. 6) with a running suture of the same catgut. Usually no packing is placed postoperatively, but this may be done if there is excessive oozing.

In this series the posterior incision was used throughout, with the exception of an anterior approach to an anterior ovarian cyst in one case and to an unruptured ectopic pregnancy in another.

Procedures Performed.—In the 94 women in this study on whom colpotomy was performed, there were many different indications for this operation. They included known ovarian cyst (29); known ectopic pregnancy (3); adnexal mass (18); tubal ligation (10); and miscellaneous (6). On the basis of general diagnosis alone 14 patients underwent the operation, and in 18 it was performed as part of an infertility study.

Posterior or anterior colpotomy with a large incision allows for maximum maneuverability and a wide choice of diagnostic and surgical therapeutic procedures. It enables the operator to make a satisfactory and complete diagnosis in the pelvic area. There is no distortion by magnification, and the organs are in their normal relationships. Diagnostic procedure or surgical intervention does not necessitate any change of position or draping. The incision can always be extended, if necessary, and with proper retraction considerable pelvic surgery can be accomplished.

The following are procedures carried out in this series: (1) exploration of the pelvis for differential diagnosis; (2) salpingectomy, unilateral and bilateral; (3) resection of ovarian cyst, unilateral and bilateral; (4) oophorectomy, unilateral and bilateral; (5) bilateral wedge resection of the ovary; (6) lysis of ovarian, tubal, uterine, intestinal, peritoneal, and omental adhesions; (7) visualization of the appendix and cecum; (8) evacuation and drainage of large ovarian cystic structures; (9) infertility studies (including direct observation of the ovary, for example, to see and perhaps even perform a biopsy on a corpus luteum; observation of fallopian tubes with injection of methylene blue to determine patency; removal of previously placed plastic tubes and hoods; tubal plastic operations; and observation of ovulation); (10) sacrouterine neurectomy; (11) sacrouterine plication for third-degree retroflexion and retroversion; (12) Pomeroy's operation (ligation and resection of fallopian tubes); (13) removal of ectopic pregnancy, ruptured and unruptured; (14) excision of enlarged cysts of Morgagni; and (15) removal of pedunculated myomas.

Anterior colpotomy can also be done for anterior ovarian cyst or for ectopic pregnancy which cannot be brought down into the posterior incisional area. This involves more dissection but can be done without great difficulty when the patient is a multipara. Particular attention to anatomy, especially to the bladder and ureters, and care in making the incision sufficiently wide, are factors which facilitate the anterior approach. It is advantageous to be able to use the anterior approach under certain circumstances; for example, in a situation in which it is not possible to turn the uterus into retroversion, when this is needed. Care must be taken to avoid the bladder or ureters as well as the perivesical venous plexuses.

Findings and Results.—At colpotomy were found ovarian cysts (34); ectopic pregnancies, ruptured (3) and unruptured (2); pelvic inflammatory disease (17); postoperative adhesions (6); endometriosis (5); and myoma (1). In 30 patients no gynecologic disease was found. Of the 14 patients who underwent colpotomy on the basis of general diagnosis alone, 2 had ectopic pregnancies; 2, ovarian cysts; 3, pelvic inflammatory disease; 2, postoperative adhesions; and 5, no gynecologic disease. Of the 18 patients in

whom the indication for colpotomy was the presence of an adnexal mass, 2 had ovarian cysts; 14, pelvic inflammatory disease; and 2, endometriosis.

The 34 ovarian cysts found in the sample were classified as follows: dermoid, 3; pseudomucinous cystadenoma, 1; fibroma, 1; endometrioma, 2; polycystic disease, 5 (inflammatory, 4; Stein-Leventhal, 1); Morgagnian, 1; corpus luteum, 10 (5 with and 5 without hemorrhage); and follicle, 11 (3 with and 8 without hemorrhage).

Of the 94 patients in the sample, 84 had an uncomplicated recovery. Five developed postoperative complications and five subsequently underwent laparotomy. The entire procedure was unsuccessful in only three. The average postoperative stay in hospital for all patients was three and one-fourth days. The results are a justification of the procedure, which is less traumatic than exploratory laparotomy and can be used in many situations in which an exploratory laparotomy is not really indicated.

Comment

The primary value of colpotomy is investigation of the pelvis by direct exploration without laparotomy. It is of further importance that such exploration can be followed by surgical therapeutic measures at once from below. It is especially useful in relation to tubal and ovarian disease. It has a specific use in the observation and treatment of symptomatic, persistent, small ovarian cysts in young women. These smaller masses have been a matter of concern to gynecologists for a long time, because when the final diagnosis and treatment of these masses indicates an abdominal incision, it is not a minor matter. Many ovarian cysts can be observed, resected, or removed through a posterior colpotomy incision, thus eliminating the necessity for abdominal exploration.

It is unfortunate that one of the least diagnosed diseases in gynecology is ovarian cancer. More frequent use of the posterior colpotomy incision facilitates the early diagnosis of this disease, because one of the most valuable aspects of the procedure is the direct observation of ovarian tissue. The presence of a solid or questionable tumor is an indication for laparotomy. If the cyst should prove to be innocent, it often can be removed vaginally. Intraperitoneal fluid can be aspirated and spun down to verify an unusual or questionable lesion whenever indicated. What is most important is that, since this is relatively a less complicated procedure than the abdominal exploratory operation, familiarization with its use will lead to earlier and more frequent intraperitoneal investigation of ovarian masses. Conservation of the ovary is the best practice except when such conservatism leads to the preservation of an ovarian cyst for an extended length of time, bringing about eventual necrosis of ovarian tissue.

Another important application is that it is possible, when a diagnosis of mild pelvic inflammatory disease is made, that lysis of tubal adhesions can be accomplished, thus occasionally making it possible to establish tubal continuity or to prevent the continued formation of adhesions which permanently destroy the tube.

In the presence of other pelvic disease, posterior colpotomy can easily be converted to vaginal hysterectomy or pelvic repair, if such procedure should be indicated at the time of surgery. It has long been a practice of a well-known gynecologist (Dr. Allen of Chicago) to do a posterior colpotomy, along with a dilation and curettage, prior to every vaginal hysterectomy. This simple transvaginal incision has been extended in this series to include sacrouterine neurectomy in cases of dyspareunia, dysmenorrhea, pelvic pain, and some cases of infertility.[3] Section of the sacrouterine ligaments can be done to enlarge the incision. Plication of these ligaments without section can be done for the prevention of enterocele.[4] The transvaginal approach to the peritoneal cavity has great value for women, correctly or incorrectly labeled hysterical or neurotic, who manifest a desire for repeated abdominal operations for vague pelvic or abdominal pain. In these instances it is of great help to be able to eliminate doubt as to real or fancied pelvic disease.

It has long been felt that the freeing of one set of adhesions through an abdominal incision has merely served to create another set. Yet there are many individuals who are relieved for a long time by the lysis of pelvic or postoperative abdominal adhesions through a colpotomy. The same is true in an apparently symptomatic pelvic condition in which a definite diagnosis of uterine or adnexal disease cannot be made. The symptoms are often of a nature which makes it impossible to examine or evaluate these patients adequately. In such patients the use of the posterior colpotomy is valuable not only in obtaining factual knowledge but also for psychological reasons. The use of the operation in these cases provides a simple and satisfactory exploration for diagnosis without involving the patient in an abdominal laparotomy. Its advantages over laparotomy are that it is, by contrast, a minor procedure; that postoperative convalescence is much shorter; that postoperative discomfort and complications are greatly reduced; that there is less tissue trauma; that symptomatic, intra-abdominal adhesions are fewer postoperatively; that the time required for the procedure is less; and that the operating room set-up is the same as for simple dilation and curettage.

The use of posterior or anterior colpotomy is by no means a panacea in gynecology, but it does have major advantages as a diagnostic and therapeutic tool which have been overlooked for too long. Its use can contribute in great measure to early diagnosis of ovarian carcinoma. It also permits many gynecologic diagnostic and surgical procedures to be accomplished at far lower cost and with much less hospitalization than are involved in exploratory laparotomy.

FUNCTIONAL FASHIONS FOR THE PHYSICALLY HANDICAPPED

Howard A. Rusk, M.D.
and
Eugene J. Taylor, New York

The need of specially designed garments for physically handicapped people is becoming evident from the statistics regarding various types of disability in this country. The need can be met by a constructive program. Examples are given of clothing that is easy to put on, wear, and take off, that resists the friction of crutches and the strain of laundering, and that improves the morale of severely disabled persons. A coat-dress and a suit-dress for women and slacks for men are described in some detail. Continued research on patterns and fabrics is necessary. Problems of direct mail selling must be solved. Concerted effort in this field will help to overcome existing difficulties in the way of self-help, vocational rehabilitation, and social adjustment for millions of handicapped people.

As the result of a three-year research program, physically handicapped persons now have available for the first time a number of specially designed garments which combine fashion with function. The project had its inception when Mrs. Helen Cookman, a top "name" designer in fashion circles, was invited to become the consultant in clothing for the disabled to the Institute of Physical Medicine and Rehabilitation, New York University–Bellevue Medical Center.

Prior to this time, the occupational therapy division of the Institute of Physical Medicine and Rehabilitation had been concerned with the lack of specifically designed clothing for physically handicapped persons as a part of its long-term activities in the design, testing, and dissemination of information of self-help devices for the handicapped under a grant from the National Foundation.[1]

Definitive statistics are not available on the numbers of persons with varying types of physical disabilities who might profit from the availability of specially designed clothing. An approximation of the number, however, is indicated by the estimate that over 1,800,000 persons in the United States have suffered from strokes. The need for such clothing had made itself evident not only through the needs of the patients at the Institute of Physical Medicine and Rehabilitation but through numerous letters received regularly requesting information on the possible availability of such clothing.

Prior research by the staff of the Institute of Physical Medicine and Rehabilitation had shown that the clothing problems of physically handicapped persons centered around (1) design to permit greater ease in putting on and removing garments by individuals with limited muscle strength and limited range of motion in the various joints and by individuals who rely on braces, crutches, wheel chairs, and other mechanical aids; (2) design to permit greater social acceptance and increased self-esteem by severely disabled persons; (3) fabric choice to resist the undue wear caused by greater tension on the cloth as a result of the more strenuous physical activities required by certain disabled persons in dressing and undressing; undue wear caused by the friction of braces, crutches, wheel chairs, and other appliances and devices; and laundering and related care of clothing.

The results of the three-year research effort headed by Mrs. Cookman were first presented at a press showing in New York last October and then at another showing later that month before the

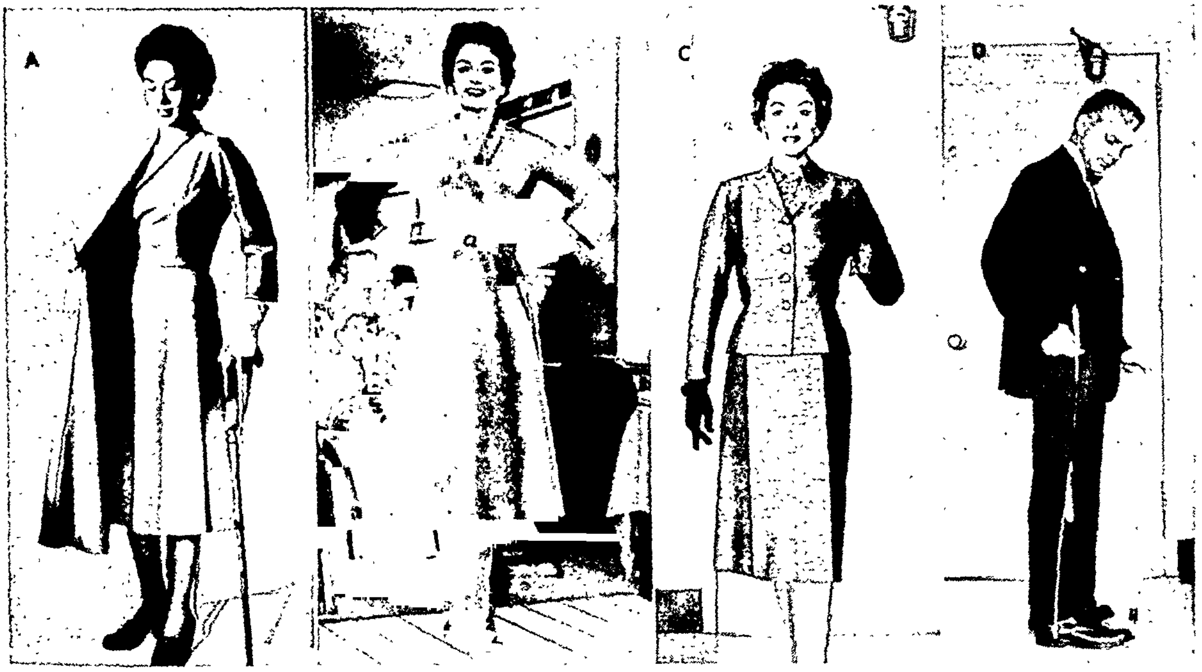
---

From the Department of Physical Medicine and Rehabilitation, New York University–Bellevue Medical Center.

annual meeting of the American Occupational Therapy Association. There were 17 models presented at these showings—tailored suits, slacks, blouses, dresses, dinner skirts, and gloves for women, and vests, shoes, ties, and suits for men.

Each of the models had been thoroughly trial-tested prior to manufacture. Testing based on function, utility, and fabric choice was conducted over a six-month period by disabled patients and staff members of the Institute of Physical Medicine and Rehabilitation, a number of whom wore each of the various models. Their suggestions were incorporated into redesigns, and then the redesigned models were tested.

Fabrics were chosen with deliberation after many months of checking with the Du Pont laboratories. They are mostly wash-and-wear nylons and Dacrons stitched with the strongest threads available, but care has been taken that the fibers do not generate too much electrostatic charge and will not cause wheel chair problems by sticking instead of sliding. Emphasis was also given to the use of closures which could be easily managed.



A, coat-dress, opened; *B*, coat-dress, closed; *C*, suit-dress; and *D*, man's slacks.

Currently six of the items in the collection have been produced by a new, nonprofit organization, Clothing Research, Inc., which is conducting a market test through the direct mail selling of these items. A large number of organizations contributed materials, skills, and time to the production of the current inventory of Clothing Research, Inc. Proceeds from the sale of these garments will be used for the further testing and development of new garments. Catalogs of the six items now available can be secured from Clothing Research, Inc., 307 W. 38th St., New York 1.

The Coat-Dress

Among the six items now available is the coat-dress (fig. 1 *A* and *B*). This garment was specially designed to counteract the destructive effect of crutch-walking on clothes—the pull across the shoulder blades and wear under the arms; to give greater ease in putting the garment on and taking it off; and to give greater comfort in wearing. The coat-dress is cut with extra width across the shoulders to provide more room for crutch-walking. Material is double under the arms at the side seams so that when the fabric wears from the crutches, the top fabric may be turned in for additional services from the fabric underneath.

The bodice is styled to hug the neck close and is cut wide across the chest so that crutch-walking motions will not pull it open. Sleeves are roomy enough to allow for well-developed arm muscles. The garment is buttonless and utilizes a single extra-large hook and bar closing at the waistline, thereby making dressing and undressing simple. The generous overlap of skirt insures that the dress will not come open, regardless of how active the wearer may be. The coat-dress is available in three colors in a range of sizes in crisp, crease-resistant fabric of 50% viscose rayon and 50% acrylic fiber (Acrilan).

The Suit-Dress

The currently available suit-dress (fig. 1*C*) is a classic, tailored garment with special features of value to crutch-users. These special features include inverted action pleats coming from the shoulder in front and a pleat at the center back allowing needed roominess for crutch-walking, for rising from chairs, and for getting in and out of an automobile. As with the coat-dress, fabric below the arms at the sides is double-thickness to withstand the rubbing action of crutches; when the top fabric wears through, it can be turned under a new, unworn piece of suit material. The jacket sleeves are made to allow for well-developed arm muscles.

The skirt has a heavy-duty, easy to reach, extra-long 12-in. zipper. The waistband closes with a new miracle fabric closure (Velcro). The wearer merely presses it shut and tiny nylon links mesh together to form a band that holds firmly but opens quickly and easily at a gentle tug.

The suit-dress is currently available in three colors in a range of sizes in a smartly slubbed menswear suiting fabric of year-around weight of 45% viscose rayon and 55% polyvester fiber (Dacron).

Other garments now available for women include slacks, a belt-pocket unit, and a wheel chair cape.

Men's Slacks

The only item currently available for men is slacks (fig. 1*D*), which have the following features: (1) two-way, heavy-duty, side-seam gripper zippers that open either top or bottom, and wide zipper facings that protect the leg and prevent zipper sliders from snagging underclothing; (2) button tab waistband fastenings and zipper fly front closing; (3) inside half belt that may be worn either toward front (for front drop) or toward back (for back drop) and that may be adjusted by changing button location on inside of waistband; (4) two front pockets with opening angled for easy access when sitting and two back pockets (one with button closing); (5) pleated fronts for comfort when sitting; (6) lined knees to protect pant legs from the abrasive action caused by knee locks of braces; (7) precuffed bottoms (when ordering, exact measurement of both waist and inseam must be given); (8) ample material in seat seam and at waist to allow for alteration if required; and (9) belt loops in matching fabric and color to be attached by wearer if he wishes to use a belt.

The men's slacks are available in two colors in a range of sizes in a medium-weight gabardine of 35% viscose rayon and 65% Dacron.

If the current market test indicates a sufficient market for the specialized line of "Functional Fashions for the Physically Handicapped," additional garments will be produced as the designs become available and will be distributed through normal commercial distribution channels.

In the meantime, while the market test is under way, research, development, and testing of new garments by the Institute of Physical Medicine and Rehabilitation will continue with the aid of a grant from the Office of Vocational Rehabilitation, Department of Health, Education, and Welfare. It is hoped that the project will eventually be extended to cover all basic garments for children of all ages and winter outwear, rain wear, sleeping garments, underclothing, and other garments for handicapped men, women, and children.

SARCOIDOSIS AND THE KVEIM REACTION.—There is now evidence that sarcoidosis may be caused by an acid-fast spore, which is a pine-tree pollen. The occurrence of the disease predominantly in areas of pine-tree forests and among the rural residents of such areas, the recovery of the spore from patients and other findings recently reported indicate that the etiology of this disease may soon be known. The frequent difficulty in differentiating this disease from tuberculosis is not often overcome by the use of globulin determination, as the same change occurs in both diseases. Although the alpha fraction is often elevated along with the gamma globulin in tuberculosis and the gamma fraction is usually much more elevated in sarcoidosis, often recourse must be had to other laboratory means such as radiographic, bacteriologic and biopsy. The recently described Kveim test is said to be specific in the diagnosis of sarcoidosis. The Kveim reaction in sarcoidosis is a valuable diagnostic test. It is performed by the intracutaneous injection of a heated sarcoid lymph node or splenic suspension. If the test is positive, a violaceous papule appears at the site of inoculation within 3 weeks. It may reach a diameter of 5 to 10 mm. in 6 to 8 weeks. The lesion is similar histopathologically to sarcoidosis. The test is highly specific. Since it requires sarcoid material as a necessary ingredient, it is probably in the nature of an antigen-antibody reaction. In support of this are the following experimental findings: if gamma globulin from a sarcoidal patient or Kveim antigen is injected into a normal skin, only a mild reaction occurs; however, if they are mixed and then injected, a lesion similar to a typical sarcoid results.—P. G. Weil, M.D., Plasma Proteins, *American Practitioner and Digest of Treatment,* September, 1958.

DEPRESSANT ACTION OF LOCAL GASTRIC HYPOTHERMIA ON GASTRIC DIGESTION

USE IN CONTROL OF MASSIVE HEMATEMESIS

Owen H. Wangensteen, M.D., Harlan D. Root, M.D., Peter A. Salmon, M.D.
and
Ward O. Griffen Jr., Minneapolis

The retardation of peptic digestion at low body temperatures first observed in vitro was found to be equally striking in vivo. Small animals, if sufficiently chilled and supplied with oxygen, were protected from digestion in the stomach of larger animals. This fact was applied in treating 19 patients who had unrelenting hemorrhages from the duodenum, stomach, and esophagus. A technique was evolved for circulating a coolant through a system of tubes and balloons in the stomach. The first experiences were encouraging, particularly in nine patients who had been bleeding profusely from duodenal ulcers and who ceased to bleed on cooling without recourse to operation. This therapy is rational for situations in which the digestive activity of gastric juice may be responsible for continued erosion and hemorrhage. It should not be relied on in situations complicated by blood dyscrasias, carcinoma, and other miscellaneous disorders.

William Beaumont and Alexis St. Martin more than a century ago wrote into the history of gastric physiology an immortal chapter on the nature of gastric digestion. Beaumont pursued relentlessly investigation of the digestive action of gastric juice on foods introduced into the stomach of Alexis St. Martin, a young French Canadian engaged in fur trading, who suffered a shotgun blast into his upper left abdomen and thorax which exposed the lung and tore a large rent in the anterior gastric wall. Beaumont managed the care of this mortal wound so skillfully that St. Martin, after a period of disability of three years, was restored to good health. Then began a series of observations interrupted by a period of four years in which Beaumont found it necessary to institute a search for the whereabouts of his unwilling subject who had absconded to Canada. These studies were commenced at Fort Mackinac Island, in the straits of Sault Sainte Marie, and continued, after St. Martin's long unannounced leave, at Fort Crawford in Prairie du Chien, Wis. All of Beaumont's experiments were done in military outposts of the United States Army; the final observations and experiments were performed in the city of Washington, and at Fort Niagara, N. Y. While his assignment was to look after the militia who aimed to preserve peace with the Indians in the areas of military outposts on the frontier, Beaumont found time to perform experiments on gastric secretion and digestion which excite our admiration today.

Beaumont's first publication was brief, recording three experiments performed in 1825. His epochmaking monograph summarizing his studies was published in 1833. Forty years after the appearance of this distinguished work, entitled "Observations on Gastric Digestion," there were still skeptics who were not convinced that the stomach secreted hydrochloric acid. In fact, Austin Flint Jr., who began his career as a physiologist in Buffalo, near where Beaumont performed his last observations on Alexis St. Martin in 1833, believed (1873) that the chief secretion of the stomach was lactic acid. He had been abetted in this belief by some observations Claude Bernard made in 1844, 11 years after the publication of Beaumont's monograph. Bernard's well-known experiments, in which the legs of frogs were submerged through a gastrostomy opening in the gastric juice of a dog's stomach, have served to mitigate the earlier serious error of Bernard's deductions concerning the nature of the acid in gastric juice.

Prior to Beaumont, it was generally believed, despite the observations of Réaumur (1752), Stevens (1777), Spallanzani (1785), and Young (1803), that gastric digestion was largely a triturative process, that it was the force of the gizzard in birds and of the gastric antrum in mammals which was largely responsible for the digestion of foods. Beaumont brought forth convincing evidence that gastric digestion was an active chemical process.

However, Beaumont failed to note the presence of an active enzyme in gastric juice. Schwann (1836), a pupil and colleague of Johannes Müller, boiled gastric juice and noted it had no digestive action on food. Schwann rightfully concluded there was an enzyme in gastric juice responsible for digestion, which he called pepsin. Wassman in 1839 elaborated on the observations of Schwann. The historic work of Rudolf Heidenhain (1870, 1878, 1883) of Wroclaw (Breslau), Poland, served to establish the presence of parietal (acid-secret-

ing) and chief cells (pepsin-secreting) in the stomach. It remained for Langley (1880-1882) to establish the presence of pepsinogen, the precursor of pepsin.

The linear relationship between enzyme action and temperature has long been known; that cold depresses peptic activity is known to every student of chemistry and biology. However, no special use has been made of this knowledge in the control of pepsin action in gastric digestion.

Assessment of Digestive Power of Gastric Juice

It is almost 20 years (1939) since gastric resection was first employed by one of us (O. H. W.) in the control of idiopathic esophageal stricture,[1] which it is perhaps now safe to label peptic stricture of the esophagus. It soon became apparent that this sensitivity of the esophagus to injury was owing to the circumstance that squamous epithelium does not resist digestion as well as the glandular epithelium of the stomach and upper reaches of the intestinal tract. These observations served to suggest perfusion of the cat's esophagus to assess the potential digestive action of gastric juice. For more than a decade in this clinic, the peptic activity of gastric juice has been determined by observing the damage done to the mucosa of the esophagus of the cat attending perfusion of the esophagus with gastric juice. It is noteworthy that perfusion with gastric juice obtained by overnight gastric aspirations of patients with duodenal ulcer quite regularly causes perforation of the cat's esophagus within a period of two hours when such juice is dripped into it.[2] Moreover, it is the pepsin that is responsible for this action. Hydrochloric acid in the range of the lowest pH levels that can be recovered from the stomach (0.1 *N*) fails to damage the esophageal mucosa noticeably on perfusion. Moreover, there appears to be no influence of temperature, within the physiological range, on the action of hydrochloric acid. When the gastric juice from a patient with duodenal ulcer is cooled and perfused through the esophagus of a cooled cat, the esophagus fails to exhibit evidence of esophagitis or perforation attending perfusion in the warm state (fig. 1).

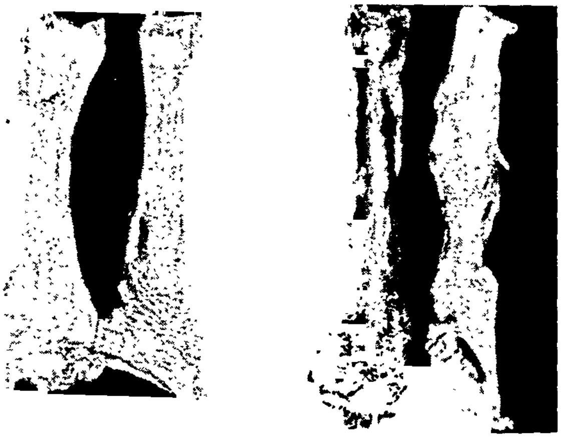

Fig. 1.—*Left*, esophagus of cat cooled to 25-30 C perfused with gastric juice cooled to 20 C obtained from patient with duodenal ulcer; results were 1+ to 2+, with little or no effect on esophagus. *Right*, esophagus of control cat at temperature of 37 C perfused with gastric juice at temperature of 37 C from patient with duodenal ulcer; results were 4+ to 5+, with severe esophagitis and perforation.

Effect of Systemic Hypothermia on Gastric Digestion—Fish and Small Animals

After completion of the observations just described, a study was undertaken of the influence of cold on gastric secretion and digestion, employing general and local hypothermia; observations were made on several animal species.[3] The desired levels of hypothermia were attained by reducing the environmental temperature in poikilothermic animals such as the fish, frog, toad, and snake and by brief immersion in ice water in small animals.

Two species of fish, trout (Salmo irideus) and catfish (Ameiurus nebulosus), were studied by measuring the rapidity of the digestion of a test minnow. Digestion of the minnow by a trout kept at 17 C was complete in 8 hours, but at 2 C, 17 hours were required to produce a similar result. The period of time required by catfish for complete digestion of the test minnow was somewhat longer, 16 hours at 20 C and 48 hours at 5 C. Only in fish have we encountered pepsin still active at 2 C.

Similar studies were carried out in frogs, small spring frogs being introduced manually into the stomach of large intact bullfrogs. Digestion of the small frogs in the stomachs of the bullfrogs kept at 26 C was essentially complete in 24 hours, whereas, when the temperature was maintained at 2 C, the spring frog was still alive after 11 hours (fig. 2), dead but intact at 24 hours, and only slightly digested at the end of a week. The digestion of decapitated and pithed frogs under similar circumstances produced equivalent degrees of digestion. The rate of digestion of spring frogs by toads differed only slightly from that reported for the bullfrog, being somewhat faster at 26 C and considerably slower at colder temperatures. The digestion of minnows by bullfrogs and toads maintained at 26 C was complete in 12 to 16 hours, while at 11 C little digestion had taken place after 72 hours.

The digestion of spring frogs by king snakes was also markedly slowed by hypothermia. At 33 C, tissue digestion was complete in 10 hours, while at 7 C, little digestion had occurred after 72 hours.

Studies of digestion in small mammals under general hypothermia were carried out with use of fasted white rats. They were first fed 2 Gm. of lean beef and then either immediately cooled to 20 to 25 C or kept normothermic. It was found that in six hours 98% of the meat was digested by the normothermic rat and only 2% was digested by the hypothermic animals.

Effect of Systemic Hypothermia on Gastric Digestion—Man and Dog

Technique of Achieving Local Gastric Cooling.—Local gastric hypothermia was achieved in man and the dog by circulating a cooling solution (equal parts ethyl alcohol and ice-cold water) through an intragastric balloon. Constant temperature and circulating volume were maintained by a hypothermia machine.

In Vivo Meat Bolus Digestion Studies.—In man, the rate of digestion of a 2-Gm. meat bolus contained in a wide-mesh, gauze sack was measured under normothermic and hypothermic conditions. The meat bolus was ingested by the subject and retained for four hours. It was then retrieved and a new bolus was swallowed and retained for an equal period. During the first four-hour period the intragastric balloon contained fluid at 38 C, while throughout the second four-hour period the cooling solution was circulated through the balloon to keep the stomach hypothermic. In human subjects, the mean weight loss of the bolus during the period of gastric cooling was 18%. In normothermic subjects, the mean weight loss of the bolus was 55%.

Data obtained from similar studies in dogs confirm these findings. The rate of digestion of a 2-Gm. meat bolus by gastric juice was studied in vitro at 37, 20, 11, and 5 C. Aliquots of juice were obtained from dogs with Heidenhain pouches after stimulation with meat, pilocarpine, and histamine. Specimens of unstimulated gastric juice were obtained from patients with duodenal ulcer and gastric ulcer and from those without gastric or duodenal lesions. Weight loss of the meat bolus at 37 C over a period of 10 to 21 hours was between 70 and 80%, while at 11 C the weight loss of the bolus was only 0 to 10%.

Influence of Local Cooling of Stomach on Volume of Gastric Secretion

The effect of hypothermia on the volume of gastric secretion was studied in human and canine subjects. In man, a no. 18 plastic nasogastric tube, connected to a continuous source of suction, was used to collect secretions; in the dog the pylorus was ligated and all secretions were collected by means of a gastrostomy tube. After placement of an intragastric balloon, gastric juice was collected for a two-hour period at normothermic temperatures; thereafter the stomach was cooled and hourly specimens were obtained during the ensuing four hours.

Interpretation of these data shows that the mean reduction in volume of gastric secretion after the initiation of hypothermia was 80% in man and 90% in the dog. Total free acid and total pepsin production were also markedly reduced.

Another experiment afforded lucid proof of the depressant effect of local gastric hypothermia on gastric digestion. An oxygen line, employing a polyethylene tube (no. 90), was fastened with a stitch to a small frog's nose. He was then immersed through a gastrostomy opening into a dog's stomach which was cooled to 4 C. When removed at 36 hours, the little frog, though at first inactive, was still alive and jumped as far as he ever did. His mate, who had been immersed in a warm dog's stomach, even though provided with an oxygen line, was well digested and died within a few hours (fig. 3).

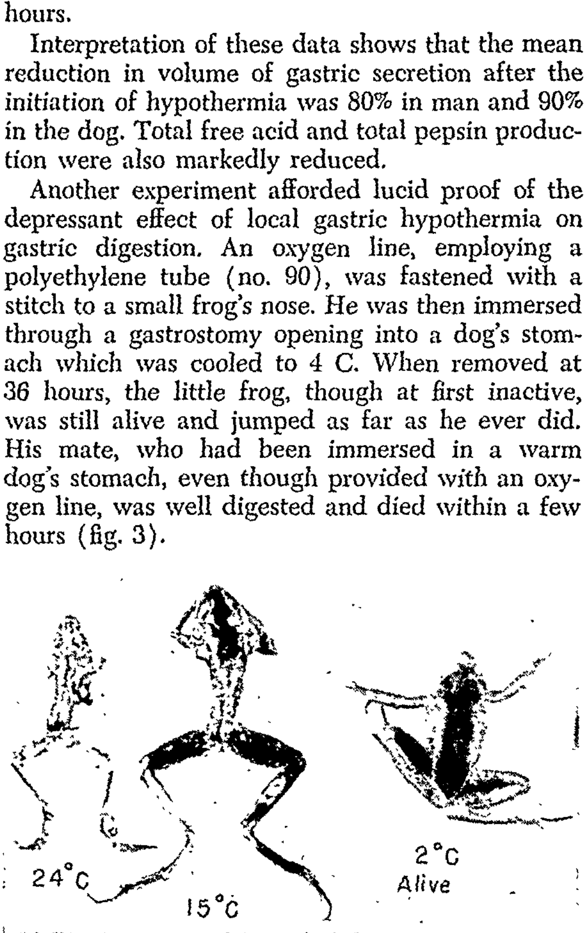

Fig. 2.—Digestion of three small spring frogs kept for six hours in stomachs of bullfrogs shows marked difference in degree. At 24 C spring frog was about 50% digested, at 15 C it was about 20% digested, and at 2 C frog was still alive. At 2 to 4 C small frogs have survived up to 20 hours within a bullfrog's stomach.

Technique of Local Gastric Hypothermia in Control of Massive Gastric Hemorrhage

The foregoing experiments suggested that control of massive gastric hemorrhage might be achieved by use of local gastric cooling.

In a study of the vital statistics of the ulcer problem in Minnesota, Casey[4] found that death from acute massive hemorrhage occurred in 42% of all patients who died from peptic ulcer in that state. In two-thirds of all deaths, hemorrhage played an important role. Emergency surgical treatment of massive upper gastrointestinal hemorrhage also carried with it a formidable mortality. The patients are usually in shock, with markedly reduced blood volumes. The additional stress of surgery is poorly tolerated by such patients. The site of bleeding is often unknown, thereby complicating and prolonging the surgery. The use of any agency which would make it possible to avoid surgery at such a time would be welcomed by everyone concerned.

Method of Cooling.—The machine now used (fig. 4) to induce gastric hypothermia has been greatly improved over the "homemade" model described in the original report.[3] This machine, while retaining the same basic components, has a number of distinct improvements. The circulation of fluid is constant, without the interruptions formerly necessary to balance inequalities of inflow and outflow. The cooling solution is now pumped out of as well as into the gastric balloon, thus permitting the use of a double-lumen tube of a much smaller over-all diameter. The advantages of automatic shut-off, should the balloon burst, are maintained.

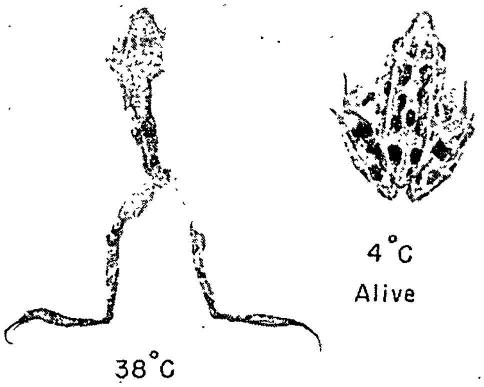

Fig. 3.—Protective effect of hypothermia. Both frogs were provided with an oxygen line by means of small polyethylene tube (*no.* 90). Frog on left was in normothermic (38 C) dog's stomach for six hours and underwent extensive digestion. Other frog was still alive after 36 hours in normothermic dog because dog's stomach was kept at 4 C by intragastric cooling balloon.

The temperature within the intragastric balloon is maintained at 10 to 14 C by an inflow of 150 to 200 ml. per minute at a temperature of 0 to —5 C. After the balloon has been passed into the patient's stomach, it is filled from a calibrated chamber so that it contains from 800 to 1,000 ml. After this, the fluid is circulated in an entirely closed system. Dial thermometers that register the temperature of the bath and the returning solution are mounted on the control panel, together with switches that control the pump and refrigeration unit. Supervision of the actively bleeding patient after initiation of gastric cooling requires participation of members from the clinical service and the cooling team, as well as nurses. As soon as bleeding appears to be controlled, further cooling may be safely conducted if a special duty nurse is at the bedside and a physician is nearby.

The machine has been in constant operation for periods up to 48 hours. During these runs the components have performed satisfactorily and in almost complete silence.

The Balloon and Its Clinical Use.—The intragastric balloon employed is one of the ordinary 10-cent rubber type, which will stretch to a capacity of about one liter. It is secured to the tubing by several turns of tightly wound 00 silk. The double-lumen tube to which the rubber balloon is attached consists of a no. 320 polyethylene inflow tube that is inserted through the side of the return tube, an 18 or 19 F. thin-walled plastic tube. The inner tube extends a centimeter beyond the end of the outer tube within the balloon. For the treatment of esophageal bleeding a 4-in. soft sheer latex balloon (condom) is attached to the tubing proximal to the gastric balloon. Two inches proximal to the gastric balloon attachment, the outer tube is constricted about the inner tube. Multiple holes bored in the outer tube both proximal and distal to the constricted point are covered by the esophageal balloon. Thus the circulating cold fluid returning from the gastric balloon is forced to flow through the esophageal balloon.

Clinical Safeguards During Cooling

Prior to the insertion of the balloon, the patient's stomach is completely evacuated of all clots by a nasogastric tube or by lavage with an Ewald tube, if deemed necessary. The patient's pharynx is then anesthetized with 5% solution of hexylcaine (Cyclaine) applied topically. Appropriate sedation is given to minimize restlessness and activity.

The empty balloon is wrapped about the end of the tubing, lubricated, and placed into the patient's mouth. The patient swallows this small bolus aided by light pressure on the tubing. Inflation of the balloon in the stomach unfolds the balloon and allows it to distend the stomach very slightly. The low temperature of the tubing minimizes the patient's discomfort. In the main, a tube in the nose is more easily tolerated by the patient than a tube in the mouth. This is an additional reason that we have reduced the diameter of the large tube initially used from 24 F. to a plastic tube corresponding in size to 18 F. In fact, for a child, a polyethylene tube no longer than 12 F. has been used.

A small nasogastric tube also is inserted beside the balloon into the stomach to evacuate blood as it appears and as an aid in evaluating continuance or cessation of bleeding. Frequent measurements of the blood pressure and occasional hemoglobin determinations also help in assessing the patient's response to local gastric cooling.

A constant-reading electronic thermometer registers the patient's temperature by means of an intrarectal thermocouple. The patient's systemic temperature usually remains normal, though external heat is quite regularly applied to insure maintenance of normal body temperature and for the patient's comfort. Mild sedation is continued as needed, and the nasogastric tube is irrigated frequently. The patient's vital signs are closely followed, and hemoglobin levels are measured every two hours. Transfusions of whole blood are continued until a normal hemoglobin level has been restored.

Despite the presence of the tubes, the alert, wide-awake patient is able to cough effectively and clear his throat of sputum and blood. In the aged, obese, or somnolent patient, regurgitation and aspiration into the tracheobronchial tree can be minimized by doing a prophylactic tracheotomy prior to intubation or soon after cooling is initiated. A semireclining position also helps to lessen the danger of tracheal aspiration. Even in the absence of frank regurgitation, stomach contents are often found in the oropharynx. In a few patients, after the start of gastric hypothermia, a few cubic centimeters of Congo red solution was put into the stomach through the nasogastric tube. The oropharynx was aspirated at regular intervals, and within 15 to 20 minutes Congo red could usually be demonstrated in the aspirated mucus of these patients. It therefore seems advisable to perform a tracheotomy early in all patients whose physical status is poor or wherever there is the slightest indication of a tendency to tracheal aspiration.

When the bleeding has stopped, as judged by the returns from the nasogastric tube and the patient's clinical status and hemoglobin values, cooling is continued only until a normal hemoglobin level is restored. Firm clot formation will usually have occurred in this period in the vessels previously bleeding, and a normal blood volume is restored, thus bringing the patient quickly to an optimal condition to withstand definitive surgical therapy should it prove necessary. The balloon is then deflated and removed. Close observation of the patient is continued, and the further management of the situation can be planned under more favorable circumstances.

Prolonged cooling of the stomach has been carried out in anesthetized animals for 48 hours and in man, up to 125 hours, without any apparent damage to the stomach or to general well-being of the subject. In well over 200 episodes of local gastric cooling on dogs and man the balloons and tubing have functioned satisfactorily without evidence of leaks or obstruction. To maintain the highest degree of safety, balloons and tubing are used only once in clinical cases.

Results of Local Gastric Hypothermia

To the present time, 19 patients with massive unrelenting upper gastrointestinal hemorrhage have been treated by the technique of local gastric hypothermia. In many instances large quantities of blood had been administered prior to the initiation of cooling. Moreover, the majority of these patients were in shock despite rapid transfusion, and hence were in a condition too precarious for emergency operation.

The patients were divided into four major categories according to bleeding site and etiology: (1) duodenum, (2) stomach, (3) esophagus, and (4) miscellaneous.

The results of treatment are as follows (see table):

Duodenal Ulcer.—Nine patients were bleeding from duodenal ulcer. At the institution of gastric cooling, six of the patients were in shock; the mean hemoglobin value was 8.5 Gm. per 100 cc., and an average of 5 units of blood had been infused. Gastric cooling was employed for an average of 15.7 hours. Prompt cessation of hemorrhage occurred in all patients.

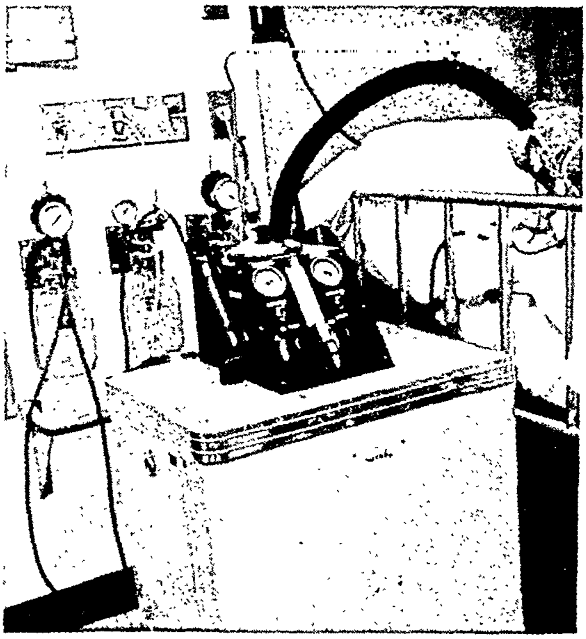

Fig. 4.—Hypothermia machine. Temperature of 10 to 14 C is maintained by pumping in mixture of ethyl alcohol and ice water at —5 to 0 C. Gauges on control panel register temperature.

The coagulation mechanisms in these patients were normal as measured by bleeding, clotting, and prothrombin times. Platelet counts were normal. It was noted that the bleeding stopped in the majority of the cases within three to four hours, as judged by the appearance of decreasing amounts of blood from the nasogastric suction. However, cooling was continued until the hemoglobin levels were returned to normal.

Gastric Ulcer.—There is only one patient with gastric ulcer. This patient, an 80-year-old female with sudden massive hematemesis, was in shock despite a transfusion of 1,000 cc. of blood. Her hemoglobin level was 8.7 Gm. per 100 cc., and her coagulation mechanisms were normal prior to local gastric hypothermia. Her bleeding stopped soon after initiation of gastric cooling, and a hemoglobin value of 13 Gm. was restored after 20 hours of treatment. No further bleeding occurred.

Esophageal Bleeding.—Three patients with massive hemorrhage from esophageal varices were treated a total of four times. Local gastric and lower esophageal cooling were achieved by the addition of a thin 4-in. latex esophageal balloon proximal to the gastric balloon, as described previously. At the onset of cooling, all of these patients were in shock and had been given an average of 6 units of blood. The mean hemoglobin level was 8 Gm. per 100 cc. Each patient had undergone unsuccessful trials with esophageal tamponade by means of the Sengstaken-Blakemore technique.

Results of Local Gastric Hypothermia in Nineteen Patients with Massive Hematemesis

			Hypothermic Course					Results		
								Operation Necessary

* Patient died before more definitive therapy could be instituted.

Intrahepatic Block (Cirrhosis): The first patient, a 55-year-old alcoholic with severe Laennec's cirrhosis, was bleeding massively from esophageal varices. His hemoglobin level prior to cooling was 11 Gm. per 100 cc. He was treated for five days, with satisfactory control of his bleeding. His hemoglobin value remained normal over this entire period, but he died from liver failure.

The second patient, also with far-advanced alcoholic cirrhosis, was admitted in shock with a hemoglobin level of 8.4 Gm. per 100 cc. Local gastric hypothermia was carried out for seven hours. Although his bleeding was slowed, it was decided to perform transesophageal ligation of his varices. His hemoglobin value at the time of surgery was 13 Gm.

Extrahepatic Block: A 21-year-old girl with congestive splenomegaly (Banti's disease) due to cavernomatous transformation of the portal vein had massive hematemesis with shock on two separate occasions. The massive hemorrhage was successfully arrested on each occasion by local cooling. She later underwent successful definitive surgical treatment.

These observations would suggest that local gastric cooling should be invoked immediately for the control of hemorrhage from the bleeding esophageal varices of portal hypertension. The observed efficacy of local gastric cooling in the control of the hemorrhage of portal hypertension lends some credence to an earlier thesis that bleeding from esophageal varices was in large measure acid-peptic in nature.[5]

Miscellaneous.—The patients in this group were bleeding from the stomach or duodenum, but unusual circumstances attended the hemorrhagic episodes. These factors were abnormal clotting mechanisms, previous steroid therapy, carcinoma, complications of surgery, and stress.

Carcinoma with Abnormal Clotting Mechanisms: Two patients had disseminated metastatic carcinoma with marked thrombocytopenia, elevated prothrombin times, and prolonged bleeding and clotting times. One patient was bleeding from a gastric carcinoma and the other from a steroid-induced gastric ulcer. Although bleeding in these patients was temporarily controlled, they were not candidates for definitive surgery and recurrent bleeding attended their terminal period.

Stress Ulcer: The stress associated with cervical fracture and resultant quadriplegia evoked massive hemorrhage in a 16-year-old boy on two separate occasions. A marked drop in hemoglobin value, massive hematemesis, and melena characterized these episodes. His bleeding promptly stopped on both occasions after the initiation of local gastric hypothermia.

Bleeding in the Patient After Operation: Two patients bled massively during complicated, prolonged postoperative courses. Both patients were in shock and had received between 8 and 10 units of whole blood replacement prior to cooling. The bleeding in one patient with a platelet count of 18,000 per cubic millimeter and a prolonged bleeding time was slowed. However, she continued to require some blood replacement and therefore operative treatment was elected while her blood volume was near normal.

The other patient had multiple ulcerations of his stomach, duodenum, and esophagus. The hemorrhage was slowed by local gastric hypothermia, but the unrecognized presence of a large firm rubbery clot in the stomach prevented efficient cooling. When the patient died unexpectedly six hours later, the hemoglobin level was 14.6 Gm. per 100 cc. This experience has taught the necessity of evacuating all clots from the stomach prior to the introduction of the cooling balloon.

Gastric Erosion with Uremia: A 13-year-old girl with chronic renal disease, thrombocytopenia, and hypoprothrombinemia had a massive gastrointestinal hemorrhage requiring replacement of 4,000 cc. of blood prior to initiation of local gastric hypothermia. The patient was in shock, with a hemoglobin level of 10 Gm. per 100 cc. Local gastric cooling produced prompt cessation of bleeding, and her vital signs and hemoglobin value stabilized in six hours. Three days later bleeding recurred to a lesser degree; it again was rapidly controlled with use of the same technique. (This patient has recently undergone successfully surgical management of urinary obstruction.)

Comment

The hazard of undertaking emergency operative measures to control hemorrhage is avoided by the employment of gastric cooling, by permitting restoration of blood volume, and by subsequent study to determine the site of bleeding and preparation for future definitive therapy. The experience with this group of cases has been a rewarding one, which has suggested definitely that depression of gastric secretion and peptic activity by local gastric cooling is of merit in the management of massive upper gastrointestinal hemorrhage.

Gastric hypothermia would not appear to be a promising method for the treatment of gastric or juxtagastric bleeding in association with metastatic carcinoma and allied disorders accompanied by low platelet counts and elevated prothrombin times. Similarly, in many postoperative states, attended by gastric hemorrhage and manifestations of deranged clotting mechanisms, local gastric hypothermia cannot be expected to elicit the same dramatic therapeutic responses as occur in peptic ulcer hemorrhage. Moreover, the terminal condition of the patients in this latter category frequently tips the scales in the direction of an unfavorable result. Nevertheless, cessation of bleeding has been achieved in a few patients in this group. A larger series of cases will be required to evaluate the usefulness of hypothermia in the control of esophageal hemorrhage.

Our small experience with local gastric hypothermia is encouraging. The method will need a longer trial in our and other hands to evaluate more precisely its advantages and shortcomings. In hemorrhage from peptic ulcer syndromes, an accurate diagnosis as to the exact site of hemorrhage apparently is not so important, whether it concerns a duodenal or gastric ulcer or hemorrhage from bleeding esophageal varices, though obviously it would be good to have precise information, if possible. Our own limited experience with hemorrhagic dyscrasias, with aberrations in the components essential to the clotting of blood, would suggest that recognition of such abnormalities is important, so that awareness of the need of invoking other therapeutic agencies may be prompt.

Summary

Gastric digestion is retarded considerably by local gastric cooling. With this procedure, a striking decrease in the volume of gastric secretion occurs. Inhibition of peptic activity is the primary cause of the suppression of gastric digestion. Observations with use of systemic cooling were made on the fish, frog, toad, and rat, and observations with local gastric cooling were made in dog and man. Only in fish have we encountered a gastric pepsin fairly active at 2 C. Even so, however, there is a notable retardation of gastric digestion attending systemic cooling in fish (trout and catfish).

Gastric hypothermia inhibits digestion of an intact frog placed in the stomach of a large bullfrog or in the stomach of a dog. In the warm animal, death and digestion of the inhabitant is a rapid and usual sequence. In the cool state, neither digestion nor death occur!

Local gastric cooling has been employed as a therapeutic adjunct in the management of massive gastric hemorrhage. Nine patients with massive hematemesis from actively bleeding duodenal ulcers have been cooled successfully, with cessation of hemorrhage and without recourse to operation. A similar result attended use of local gastric cooling in a patient with massive hemorrhage from a gastric ulcer. Three patients with portal hypertension and massive hemorrhage have been cooled. Cessation of bleeding occurred in two of these and was slowed in the other.

The method has also been used in miscellaneous conditions causing massive hematemesis, including (1) gastric and breast cancers with thrombocytopenia, (2) gastric erosions occasioned by uremia, (3) steroid ulcers with ensuant hemorrhage, and (4)

severe gastric hemorrhage in early convalescence from other surgical procedures. The results in this group have been variable—in some instances, disappointing. In others there has been slowing or cessation of the gastric hemorrhage. Obviously, these conditions do not constitute the best indications for use of local gastric hypothermia in the control of hemorrhage.

These observations suggest definitely that local gastric cooling is of promising therapeutic value in the management of massive hematemesis from peptic-ulcer-linked conditions of the duodenum, stomach, and esophagus.

Addendum

Since this paper was presented, nine additional patients have been subjected to local gastric hypothermia for massive gastric hemorrhage. Two patients had bleeding esophageal varices; the bleeding was controlled and successful definitive surgical therapy was carried out. There were three patients with severe hemorrhage from diffuse gastritis which was successfully controlled; surgical correction was done after adequate blood replacement and supportive therapy. There were two patients with postoperative bleeding which was successfully controlled. One of these, who entered the hospital with a blown-out duodenal stump, a gastric-cutaneous fistula, and complete obstruction of both afferent and efferent jejunal loops, ultimately died from peritoneal sepsis. A 4-year-old boy, treated intensively with cortisone for rheumatic fever for six weeks, bled massively twice from a steroid-induced duodenal ulcer. The first episode was quickly controlled. Owing to parental restraint and reluctance to have either local gastric cooling or surgery instituted for the second episode, only a futile last-resort attempt could be made to try to control the hemorrhage when it recurred. Bleeding was also successfully controlled in an 82-year-old woman with massive bleeding from an antral gastric ulcer, which proved, on operation, to be benign.

412 Union St. S. E. (14) (Dr. Wangensteen).

The hypothermia machine used is made by the Swenko Manufacturing Company, Minneapolis.

Just where in Washington Beaumont did his experiments on Alexis St. Martin is not known. We believe they were done at the northeast corner of 10th and E streets, N. W. If anyone has definite knowledge regarding this point, we would appreciate his sending us any information, letters or documents, giving evidence on this matter.

THE POSTMENOPAUSAL OVARY.—Urinary estrogen and gonadotropin excretion was determined in 51 normal postmenopausal women, 45 to 81 years of age, and in 30 surgically castrated women, 23 to 52 years of age. In the postmenopausal women the menses had ceased from one to thirty-three years previously. Urinary estrogen excretion of the postmenopausal women was approximately twice that of the castrated women. Although there was overlapping, the difference between the values for the 2 groups was highly significant. Estrogen excretion remained constant throughout the postmenopausal years, being the same sixteen to thirty-three years after the menopause as one to five years thereafter. Urinary gonadotropin excretion was elevated in each of the postmenopausal and castrated women. The average value for the ovariectomized women was significantly higher than the average for the postmenopausal women. Urinary gonadotropin excretion of the postmenopausal women showed no tendency to decrease with advancing years. Two postmenopausal women who received hog pituitary FSH responded with increased urinary excretion of estrogen and amelioration of menopausal symptoms. The other 4 postmenopausal women and the 2 castrated patients who received pituitary FSH did not respond. It is concluded that the postmenopausal ovary retains a small but significant secretory function and that it is the major source of postmenopausal production of estrogen.—C. A. Paulsen, M.D.; R. B. Leach, M.D.; H. Sandberg, M.D.; S. Sheinfeld, M.T.; and W. O. Maddock, M.D., Ph.D., Function of the Postmenopausal Ovary. THERAPY OF HYPERTENSION WITH ORALLY GIVEN SYROSINGOPINE

George R. Herrmann, M.D., Elmer B. Vogelpohl, M.D., Milton R. Hejtmancik, M.D.
and
James C. Wright, M.D., Galveston, Texas

Syrosingopine, a drug derived from reserpine, was administered orally to 77 ambulant patients for the treatment of essential hypertension. Group 1 consisted of 38 patients not previously treated for hypertension. Group 2 consisted of 34 patients who had been maintained on therapy with reserpine, were changed to therapy with syrosingopine, and were maintained on it for an average of three months. Group 3 consisted of five patients on combination drug therapy who had severe mental depression or other symptoms of intolerance when maintained on therapy with older antihypertensive drugs. In group 1, 16 patients (42%) responded with a clinically significant fall in mean blood pressure. In group 2 the blood pressure was controlled without side-effects by individual adjustment of dosage. In group 3 the dosage used (3 mg. of syrosingopine per day) maintained the desired antihypertensive effect without nightmares, nasal congestion, or other significant side-effects.

The effectiveness of Rauwolfia and its derivatives in the therapy of hypertension has been well demonstrated in many studies.[1] In many patients with mild to moderate hypertension, such preparations in appropriate dosage reduce the mean blood pressure 20 mm. Hg or more, and in some the blood pressure may return to normal. In other patients, usually with more marked blood pressure elevations, the Rauwolfia preparations play a useful role in combination drug therapy. The need for continuous therapy is obvious, and tolerance to the preparations after long administration has not been observed.

The limiting factor in the widespread use of Rauwolfia preparations has been the disturbing side-effects. The frequency and severity of these depend on the dosage being used. However, in the dosage range for therapeutic effect, over half of the patients have been noted to complain of such symptoms as drowsiness, terrifying nightmares, depression, nasal congestion, abdominal cramps, gastrointestinal bleeding, fatigue, weakness, dysuria, and impotence.[1b] Fortunately, only a rather small percentage of patients have experienced symptoms so severe that the drug had to be withdrawn, but such ancillary effects may make Rauwolfia therapy unsuitable for long-term administration.[2] Pharmaceutical chemists have been vigorously searching for Rauwolfia derivatives which exhibit less of these undesirable side-effects while retaining antihypertensive potency.

Syrosingopine or carbethoxysyringoyl methylreserpate (Singoserp) is one of the most recently produced synthetic compounds derived from reserpine. It was prepared in the hope of removing the undesirable attributes of the naturally occurring drugs of this class. It has been experimentally shown to be a nontoxic yet active antihypertensive agent in several species of animals, with considerably fewer sedative and gastrointestinal effects than reserpine.[3] Darvill[4] found syrosingopine to be an effective hypotensive agent in clinical studies in 28 patients, practically none of whom experienced significant side-effects.

Methods and Results of Present Study

Over the past nine months, we have studied the effects of syrosingopine administered orally to 77 ambulant patients with essential hypertension at the University of Texas Medical Branch. Patients were generally seen at intervals of twice weekly for two to three weeks for the establishment of baseline levels of blood pressure. The drug was administered in divided doses two to four times daily. At each visit throughout the study, careful clinical evaluation of each patient was made, including repeated blood pressure determinations, usually made while the patient was sitting and after a rest period of one hour. Careful inquiry was made as to possible side-effects. Laboratory studies, such as periodic electrocardiograms, blood cell counts, urinalyses, and blood urea nitrogen level determinations were made on all patients, usually at intervals of two to three weeks. The patients were divided into three groups for purposes of the study.

Group 1.—Group 1 included all patients who had not previously been treated with an antihypertensive agent and who were given syrosingopine as the first such medicament. There were 38 patients with essential hypertension admitted to the cardiovascular clinic on no medication, including 27 females and 11 males. All of the patients were Ne-

groes except four. Syrosingopine was administered to them in varying dosage. There was an initial control period of at least three to four visits, during which base-line blood pressures were established. Administration of the drug was generally begun at a dosage of 0.25 mg. given four times daily, and at times this was increased at intervals of two weeks to a maximum of 1 mg. four times daily. During this time no additional medicaments were prescribed. The duration of therapy was two to five months, with an average of three months.

* Average blood pressure reduction was —23/—12.5.

Table 1 lists the average of the blood pressures during the control period and the period when patients were on various dosage regimens with syrosingopine. There were 11 patients with diastolic blood pressure levels from 91 to 109, 16 with 110 to 119, and 11 with 120 mm. Hg or greater. Six of these patients had an initial blood urea nitrogen level of 25 to 87 mg.%, and these values remained essentially unchanged during the period of therapy.

The average blood pressure for this entire group decreased from a control value of 199.1/116.5 to 176.1/104.0 mm. Hg on the various dosage schedules. The reduction in the mean blood pressure (diastolic pressure plus one-third of pulse pressure) after therapy exceeded 20 mm. Hg in 13 patients, and the diastolic pressure returned to normal in an additional 3, making a total of 16 patients (42%) with significant clinical response. In five patients the diastolic pressure was reduced below 90 mm. Hg. The most dramatic response appeared to occur in the patients with severe essential hypertension with diastolic pressures initially over 120 mm. Hg. Six of 11 such patients showed a drop averaging 38.3 mm. Hg in mean pressure.

In individual patients, it was not possible to correlate a decreasing blood pressure with increasing doses of the drug. In two patients (cases 14 and 18), a satisfactory initial response was followed by an increase in blood pressure despite larger doses of syrosingopine. However, the blood pressures did not rise to the original control levels. This refractoriness may have been due to the progression of their arteriolar disease. Four of the 14 patients on the higher dosage levels of 3 and 4 mg. per day showed significant drops in mean blood pressure (over 20 mm. Hg), or a fall in diastolic pressure to below 90 mm. Hg. Six of 11 patients on the 2 mg. per day regimen showed significant declines in the mean blood pressure. Seven of 24 patients showed significant falls in blood pressure on the lower dosage schedule of 1 mg. per day.

Group 2.—Group 2 consisted of patients with essential hypertension treated with reserpine whose response was studied after change of medicament to syrosingopine. There were 34 patients who had been maintained on reserpine therapy alone for periods of 1 to 12 months in whom syrosingopine in varying dosages was substituted for the older drug. No other change in medicament was made during this period of observation. In a number of patients, syrosingopine was given in gradually increasing doses, with increases being made at two-week intervals. Recorded blood pressures were discarded for the first two weeks after cessation of reserpine therapy in order to avoid residual reserpine effects. Follow-up studies on patients on syrosingopine therapy were done for one to nine months (average three months).

Table 2 summarizes the therapeutic results observed in this group. The average blood pressure determination is given for each patient at various dosage levels of reserpine therapy. The right half of the table lists the average changes in blood pressure during treatment with various doses of syrosingopine. The average change on the dose of 1 mg. per day of syrosingopine in 24 patients was an increase in pressure of 0.1 mm. Hg systolic and 0.9 diastolic. There were three patients (cases 59, 65, and 70) with increases in mean pressures greater than 20 mm. Hg after being changed to 1 mg. per day of syrosingopine from previous reserpine dosages of 1 mg. per day in two patients and 0.5 mg. per day in one. One (case 40) showed a temporary decrease in mean arterial pressure of 20 mm. Hg. On the syrosingopine dosage of 2 mg. per day, 12 of these patients had an average increase in blood pressure of 2.3/1.0 mm. Hg. One patient (case 46) showed a significant increase of 32 mm. Hg in mean blood pressure, while another (case 69) showed a significant decrease of 27 mm. Hg in mean blood pressure. In six of these patients who received 3 mg. per day of syrosingopine, there was an increase in average blood pressure of 5.3/0.4 mm. Hg. One of these patients (case 59) had a significant increase of mean blood pressure of 22 mm. Hg. On the syrosingopine dosage of 4 mg. per day in six patients, there was an average decrease in systolic pressure of 1.7 mm. Hg and decrease in diastolic pressure of 3.7 mm. Hg. One patient (case 59) had a significant increase in mean blood pressure of 22 mm. Hg; two others (cases 49 and 61) had significant decreases of mean blood pressure of 31 and 21 mm. Hg.

Group 3.—Group 3 consisted of patients with severe essential hypertension on combination drug therapy who were conspicuously intolerant of Rauwolfia products. Five patients with severe hypertension on multiple antihypertensive therapy (Rauwolfia, chlorothiazide, hydralazine, and ganglionic blocking agents) were unable to continue an effective regimen because of severe intolerance to the older alkaloids. The symptoms consisted of severe mental depression in two patients and nasal congestion in three. In these five patients, attempts were made to change from one to another of the various Rauwolfia preparations (the crude derivative, reserpine, rescinnamine, and alseroxylon), but no such changes proved effective in lessening the side-effects. When Rauwolfia derivatives were deleted from the therapy, there was clearing of the side-effects but the blood pressure rose. Syrosingopine therapy in doses of 3 mg. per day was substituted for the previous Rauwolfia agents in these five patients, with as effective antihypertensive action as on the previous regimen and without significant side-effects.

Side-effects

In addition to the cases described in group 3, above, there were nine patients in group 2 who had experienced severe side-effects related to reserpine therapy. These consisted of severe and distressing nasal congestion in eight, with abdominal cramps and loose stools in one of these, and nightmares in one additional patient. The reserpine dosage on which these symptoms developed was 1 mg. per day in six and 0.5 mg. per day in three. Therapy in these patients was changed to that with syrosingopine in doses increasing to the point at which follow-up blood pressure determinations were essentially similar to those during reserpine therapy. The dosage of syrosingopine required to accomplish this was 1 mg. per day in three patients, 2 mg. per day in two, 3 mg. per day in two, and 4 mg. per day in two. Side-effects persisted in only three of these patients receiving dosages of syrosingopine of 2, 3, and 4 mg. per day. Nasal congestion persisted in one patient, nightmares in another, and abdominal cramps with nasal congestion in a third. In the latter patient, the symptoms of drug intolerance disappeared when the syrosingopine dosage was reduced from 2 mg. to 0.5 mg. per day, while the previous effective blood pressure reduction was maintained at the lower dosage.

No patients developed side-reactions with syrosingopine who had previously tolerated reserpine. Of the 38 patients in group 1, who did not receive reserpine, only one (case 4) developed a side-effect from syrosingopine. This consisted of nightmares which occurred when dosage of 1 mg. per day was given. There was good reduction of blood pressure in this instance, and therapy did not have to be discontinued as the side-effect was easily tolerated.

Pulse rates before and after the administration of syrosingopine showed no constant change, although there was considerable variation in individual patients over the time they were observed. The prominent bradycardia usually accompanying reserpine therapy was not seen. The drug appeared to produce little or no effect on the alertness of the patients, and there was no definite tendency to develop drowsiness or depression. Follow-up observations on blood cell counts and urinalyses in our patients showed no toxic hematological or renal effects. No gastrointestinal symptoms were noted except in the one patient previously discussed, who developed abdominal cramping on both reserpine and syrosingopine therapy. There was no instance of gastrointestinal bleeding.

Comment

It would appear from our studies in previously untreated hypertensive patients that syrosingopine is moderately effective as an antihypertensive drug. A significant blood pressure reduction was obtained in 16 (42%) of the patients treated with this drug alone, and in 5 of these the diastolic pressure was reduced to normal levels. These figures are roughly comparable to those observed with other types of Rauwolfia therapy. In general, patients who had been treated with reserpine could be given syrosingopine with maintenance of similar blood pressure reduction. The required dosage of syrosingopine appears to be higher than that of reserpine, but the drug is well tolerated in all dosage ranges tested.

The chief advantage of syrosingopine over other Rauwolfia derivatives seems to us to be the relative infrequency with which it produces disturbing side-effects. In our entire group of 77 patients, 14 of whom were markedly intolerant to one or several of the older Rauwolfia preparations, we observed side-effects due to syrosingopine in only four. In many hypertensive patients, the psychic and bradycardic effects of the established alkaloids may be desired; in such patients those drugs would still seem to be indicated. However, syrosingopine seems to offer a distinct advantage over the other preparations where such effects are to be avoided or when troublesome side-reactions limit their use as antihypertensive agents.

Summary

A clinical study made of syrosingopine therapy in 77 ambulant patients with essential hypertension demonstrated this agent to be effective in reducing hypertension, although the daily dosage required is higher than that of reserpine. Severe side-effects are infrequent, and this attribute of syrosingopine is its chief advantage over other Rauwolfia preparations. The drug appears useful in the management of patients with essential hypertension.

Addendum

Since this paper was submitted, we have observed a striking result of syrosingopine in a 45-year-old hypertensive man with recurrent angina at night precipitated by disturbing nightmares. Substitution of syrosingopine, 1.0 mg. per day, for the previously administered reserpine, 0.5 mg. per day, abolished the dreams and the angina. The blood pressure remained at its reduced level.

The syrosingopine used in this study was supplied as Singoserp (Su-3118) by Ciba Pharmaceutical Products Inc., Summit, N. J.

APPLICATION OF ABDOMINAL PRESSURE FOR ARTIFICIAL RESPIRATION

J. Patrick Adamson, M.D., Leon Lewis, M.D.
and
Jerome D. Stein, Ph.D., San Leandro, Calif.

A method of providing long-term respiratory assistance by intermittent abdominal pressure was tested in 15 patients with respiratory paralysis of different degrees of severity. Effective artificial respiration was provided by means of rhythmic inflation of a rubber bladder incorporated in an abdominal corset. A positive displacement pump powered by line current or 24-volt battery connects to the respirator by means of a flexible plastic base. Active assisted expiration is followed by passive inspiration due to gravitational pull on the diaphragm. Ventilation improves progressively as the trunk is flexed from 30 degrees to an optimal angle of 75 degrees above the horizontal. It was not necessary to exceed pressure of 50 cm. of H_2O at 16 cycles per minute in any patient. This method increased the range of physical activities and improved vocational potentialities for those needing life-long respiratory assistance after they have had poliomyelitis.

The rehabilitation program and daily activities of patients with residual respiratory paralysis after having poliomyelitis are often limited by the types of respiratory aids now generally available. This is true despite the fact that virtually every patient, no matter how severely affected, is now emancipated from the tank respirator at least for several hours daily. The introduction of the cuirass type of respirator has greatly increased the mobility of the patient with respiratory paralysis. The rocking bed has made it possible for many patients to sleep in comfort and to enjoy relative freedom from mechanical devices during the day. Positive pressure respirators applied by mouthpiece or trachea tube have also afforded many advantages, particularly during exercise programs and to facilitate nursing care.

Each of these devices, however, has its distinct disadvantages and interferes in one way or the other with activity. The rocking bed is only slightly less restricting than the tank, since it confines the patient to one place and limits his activity while the bed is in motion. The chest-abdomen and chest cuirass respirators are bulky and conspicuous, permit little trunk motion, and interfere with the use of upper extremities in work on tables or wheel chair trays. Intermittent positive pressure respirators require the use of cumbersome hoses, and, if mouthpieces are used, they interfere with conversation, mouth wand activities, and eating. (The mouth wand is used for activities such as page turning, typing, operation of microswitches and special telephones, and painting with oils.) The need for some type of respiratory assistive apparatus which would permit maximum breathing for activities, including work at a desk, led to the perfection of the new device to be described here.

Intermittent Abdominal Pressure Respirator

The intermittent abdominal pressure respirator (Pneumobelt), hereafter referred to as IAPR, differs in principle from the conventional devices used in the United States. It produces artificial respiration by assisting expiration rather than inspiration. It consists of an elastic inflatable flat bladder incorporated within an abdominal corset (fig. 1). As the bladder inflates the abdominal wall is compressed, the diaphragm rises, and expiration occurs; when the bladder deflates the abdominal contents and diaphragm fall as a result of gravitational pull and inspiration occurs passively. Three different corset sizes (12 in., 10 in., or 8 in. long), together with adjustable straps and movable buckles, enable satisfactory fitting to various abdominal girths and lengths. The bladder may be easily removed from or inserted into the belt. The corset is constructed of washable, preshrunk cloth and with minor adjustments of the clothing may be worn under ordinary street attire.

Cyclic inflation of the IAPR is provided by a specially constructed respirator pump (Multilung), with use of a flexible, lightweight, plastic hose connection. The respirator consists of a double-acting positive displacement piston unit driven by a 24-volt, DC-geared motor. The pump is designed to provide three types of respiratory assistance: (1) intermittent positive pressure to the airway, (2) intermittent negative pressure with cuirass respirator (the pump is of sufficient capacity to provide ventilation in patients using all sizes of chest respirators and sizes A and B [Technicon-Huxley] chest-abdomen cuirass respirators), and (3) intermittent positive pressure to the abdominal wall (fig. 2 and 3). It can also deliver intermittent positive pressure (via tracheostomy, naso-oral mask, or mouthpiece)

From the Respiratory and Rehabilitation Center, Fairmont Hospital of Alameda County, and the Department of Medicine, Stanford University School of Medicine, San Francisco. Dr. Stein is now with the Ortho Pharmaceutical Corp., Raritan, N. J.

simultaneously with negative pressure (chest cuirass respirator), or it can provide positive pressure (via tracheostomy, naso-oral mask, or mouthpiece) synchronously but in inverse phase with positive pressure to the abdomen via the IAPR. The inspiratory phase of the IAPR is arbitrarily fixed at 40% of the respiratory cycle and the expiratory phase at 60%.

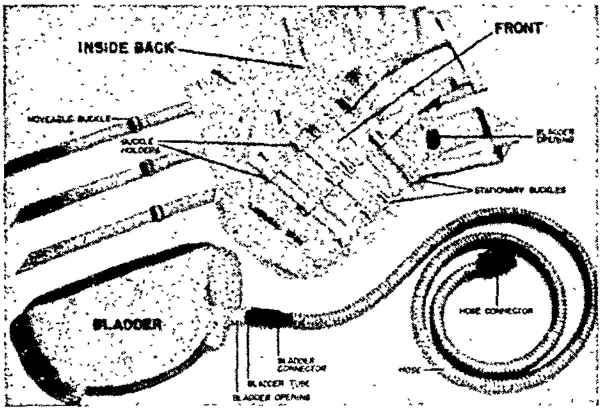

Fig. 1.—Intermittent abdominal pressure respirator: inflatable bladder and abdominal corset.

A 24-volt storage battery in a case complete with charger, charger timer, and safety fuses is provided with the unit. This battery will operate the pump for about eight hours when fully charged. The power unit contains its own rectifier so that it may be operated on 110-volt AC from a standard home utility outlet without additional accessories. Its size allows convenient placement between the rear wheels of a wheel chair. The power unit and battery charger are mounted on a small aluminum caster carrier which permits easy portability of the two parts as a unit (fig. 4). Special features of the power unit include an alarm system for power failure, respiratory rate control, independent pressure controls, a pressure safety valve, and a special intake tube to allow humidification or administration of aerosols or noninflammable gas mixtures through the positive pressure outlet for mask or tracheostomy. When the line electric current is discontinued there is automatic switchover to battery and automatic switchback to line current on its resumption. The pump can be operated manually with a hand crank on failure of line and battery current.

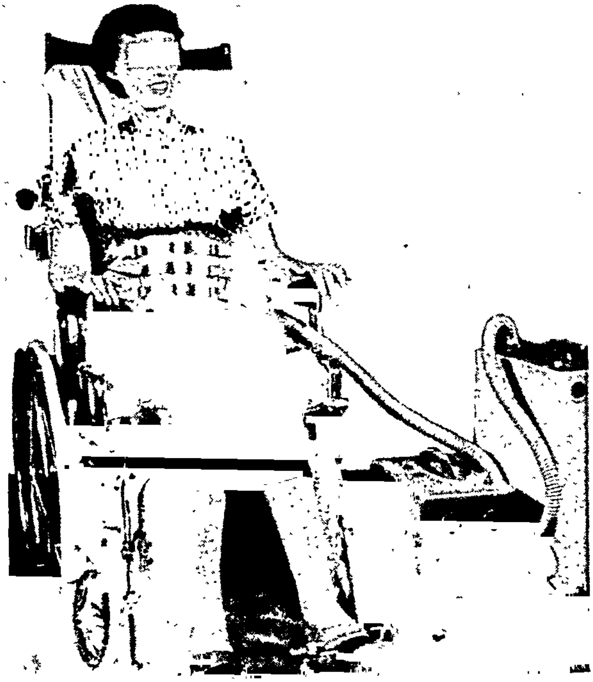

Fig. 2.—Intermittent abdominal pressure respirator with respirator pump, providing intermittent positive pressure to abdominal wall.

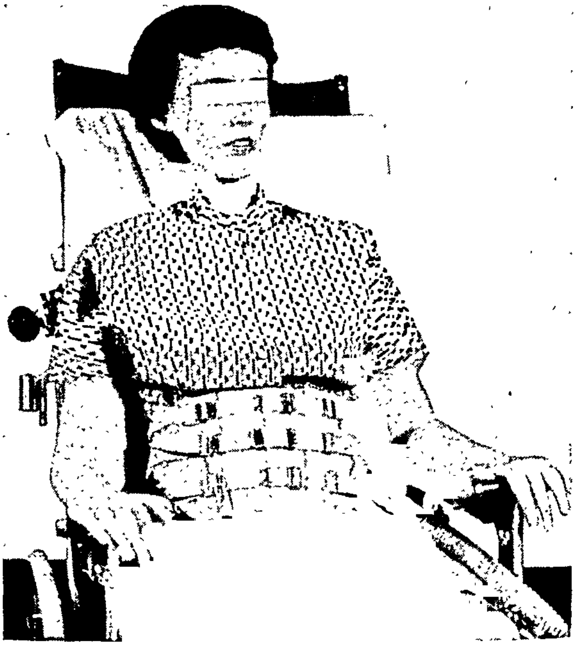

Fig. 3.—Intermittent positive pressure supplied to abdominal wall.

Testing the Respirator

Evaluation of the effectiveness of the IAPR as a method of artificial respiration was made on 15 adult subjects with paralysis of respiratory musculature due to poliomyelitis (see table).

All subjects used mechanical respiratory aids for variable periods during the day. Only three subjects had vital capacities of over 1,000 ml. Preliminary observations were also made on the use of the IAPR in the treatment of patients with pulmonary emphysema.

Subjects in a semireclining position on a stationary rocking bed were fitted with the IAPR if necessary while using positive pressure from the pump. The IAPR was then cyclically activated and the pressure gradually raised until the patient stated tidal exchange was sufficient and he was able to discard the mouth positive unit. Ventilation measurements, with use of the 9-liter Collins spirometer, were made with the patient's trunk inclined to several angles with respect to the horizontal plane and at several pressure settings for each angle. All subjects were instructed to relax as much as possible in order to permit the IAPR to take over the work of breathing. Whenever possible, arbitrary IAPR pressures of 20, 30, 40, 50, and 60 cm. H_2O and trunk angles of 30, 40, 60, and 75 degrees were selected for ventilation measurements. Eight to 10 respiratory cycles were measured, and averages were determined for each pressure and angle. Measurements were discarded as unreliable if there was more than 10% variation of tidal volume in these 8-10 cycles.

† To achieve tidal volume in 75-degree sitting position.
‡ 60-degree sitting position.

As previously mentioned, the IAPR is incorporated in three different corset sizes to enable fitting different body builds. This study did not specifically investigate ventilation differences produced by the different corset sizes in individual subjects. Choice of corset size used is based largely on the subject's build and his comfort. In general, the large size fits adult males; the medium, adult females; and the small, children. Two points regarding application of the corset deserve consideration: If the corset is applied too snugly or too loosely the IAPR loses effectiveness. Trial and error application is necessary to find the precise tightness which produces both optimal ventilation and comfort for the subject. The corset is designed with a convex lower border (to fit the suprapubic area) and a horizontal upper border. It should be applied with its upper border approximately at the level of the xiphoid in order to insure enclosure of the lower portion of the rib cage. Preliminary studies in some subjects revealed a tendency to paradoxical expansion of the chest with application of abdominal pressure. This tendency was found to be minimized by enclosure of the lower thorax by the corset.

Results of Testing

Relation of Tidal Volume to IAPR Pressure.—Figure 5 shows data obtained from three subjects in a 75-degree sitting position at various IAPR pressures. Good correlation is obtained between the pressures applied at the belt bladder and the tidal volumes measured. All other subjects showed a similar roughly linear correlation between the IAPR pressure and tidal exchange. It was noted, however, that there was marked variation from subject to subject in the absolute tidal volumes obtained at the same IAPR pressures as well as in the slope of the lines relating tidal volume to pressure. The range of variation in the "compliance" values derived from the tidal volume pressure grafts was from 3 ml. of tidal volume per cubic centimeter of water rise in IAPR pressure to approximately 90 ml. per cubic centimeter of water pressure. The reasons for the wide variation in compliance from patient to patient are probably numerous. Incomplete relaxation of subjects with unconscious resistance or assistance to air flow may be an important factor. It is recognized that valid measurements of tidal exchange could probably be made only with the patient completely under curarization. This was not feasible in this study. However, in order to minimize errors due to variation in the degree of relaxation of each subject, measurements were considered reliable only if there were little variation in the 8 to 10 tidal volumes recorded for each IAPR pressure and bed angle. Other factors concerned, in addition to pulmonary and thoracic cage compliance, may be variation in effective abdominal length and compliance of the diaphragm, abdominal wall, and related structures.[1]

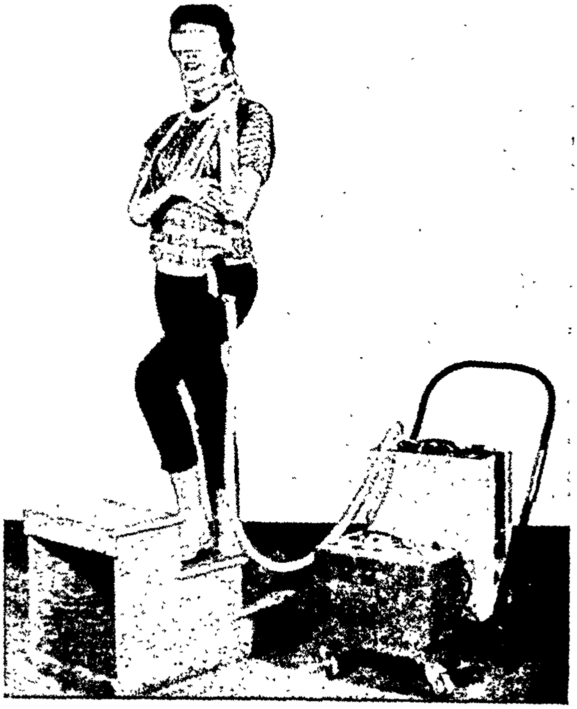

Fig. 4.—Easy portability of respirator unit.

Pressures of 50 cm. H_2O and below were uniformly comfortably tolerated. Pressures above 70 cm. H_2O usually made the patient uncomfortable. No subject was encountered who did not achieve an adequate tidal exchange at a pressure of 50 cm.

H_2O in the 75-degree sitting position. All subjects could, of course, undergo hyperventilation if pressures higher than those necessary to achieve adequate tidal volumes were used. The table shows the minimum IAPR pressure required for each subject to achieve an adequate tidal volume in the 75-degree sitting position. (Required tidal volumes were estimated from the Radford nomogram at a respiratory rate of 16 per minute.[2])

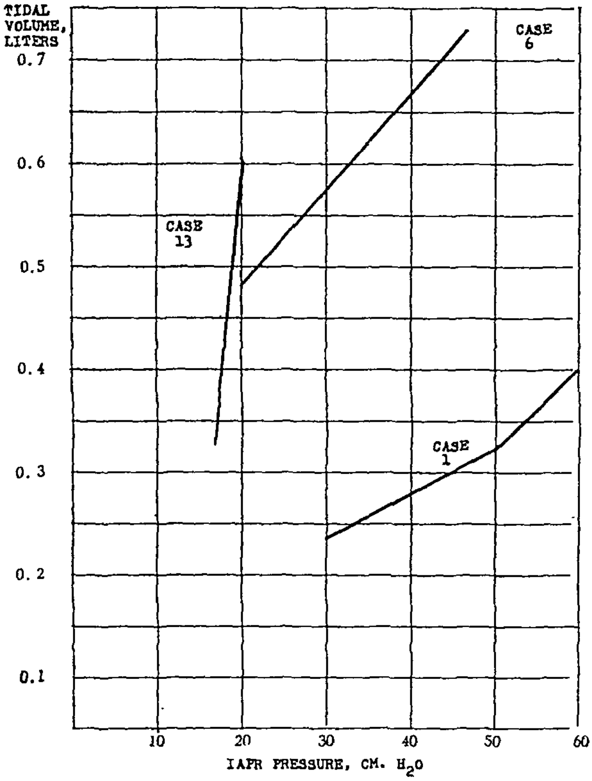

Fig. 5.—Tidal volume and required pressures in three subjects using intermittent abdominal pressure respirator.

Relation Between Tidal Volume and Angle of Trunk with Respect to Horizontal Plane.—Figure 6 shows the data obtained from a 25-year-old quadriplegic woman (case 12, see table) with a vital capacity of 800 ml. Tidal volume is shown at four different angles of the trunk with respect to the horizontal plane. It can be seen that tidal exchange is progressively improved as the subject moves from the semireclining to the sitting position. All subjects showed a roughly similar increase in tidal volume with progressive increase in body inclination from the horizontal to the vertical position. In general, the IAPR proved inadequate to move sufficient air with the subject supine. Under the conditions of measurement, inspiration is passive and dependent on the action of gravity on the abdominal contents and diaphragm. Therefore, the IAPR would not be expected to function with the subject recumbent. While one subject has been able to use the IAPR for comfortable sleeping at a reclining angle of 15 degrees, in most subjects 25 to 30 degrees is the minimal angle at which adequate ventilation can be achieved.

Comment

Use of IAPR in Rehabilitation Program.—In the rehabilitation of the patient with respiratory paralysis during the past decade emphasis has changed from a goal of freedom from respiratory aid to one of safe, maximum function.[3] This has been made possible by provision of the patient with severe paralysis with the precise amount of respiratory assistance necessary for the various activities of daily living. The IAPR has been found to be a valuable adjunct to the cuirass and positive pressure respirators in permitting this type of patient to pursue an active exercise program without developing hypoxia. We consider this device to be the respirator of choice for such activities as stair-climbing (fig. 4) and those exercises, especially of the upper extremities, best performed with the subject in the sitting position. It is also the most acceptable respiratory aid for patients who can use it for vocational activities in the sitting or standing positions.

Some patients with pronounced trunk weakness require specially designed, tailor-made body corsets in which the IAPR bladder may be simply incorporated. It may be of interest that, on at least one occasion (in work done by Dr. B. C. Kriete at the Respiratory Center of Goldwater Memorial Hospital, Welfare Island, N. Y.), the IAPR bladder has been placed under the plaster-of-Paris body jacket of a patient with scoliosis and the patient was successfully given ventilation while the cast had to be worn.

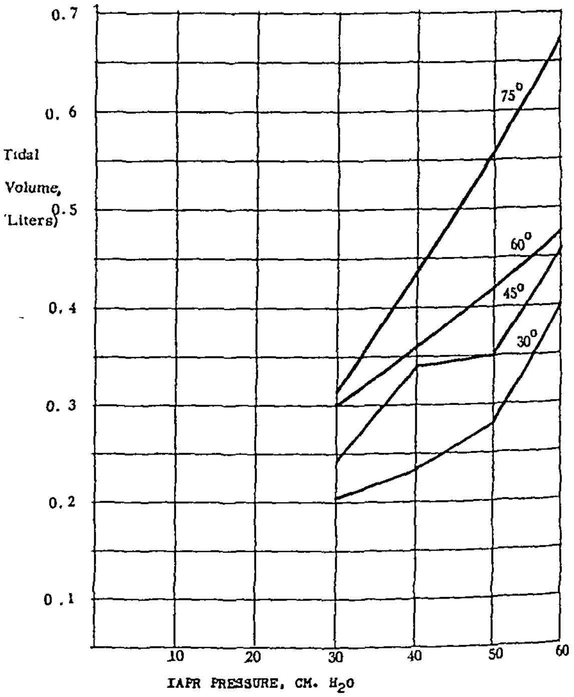

Fig. 6 (case 12).—Tidal volume and required pressures at four angles of trunk.

Use of IAPR in Nonparalytic Pulmonary Diseases.—At the present time the IAPR is used principally for long-term respiratory assistance of patients with respiratory paralysis due to poliomyelitis. Although it has been recognized that increased work of breathing plays an important part in the pathogenesis of respiratory acidosis due to chronic pulmonary disease, few workers have used prolonged respiratory assistance with mechanical respirators to relieve the work of breathing.[4] Preliminary observations on the use of the IAPR in three patients with respiratory acidosis due to chronic pulmonary emphysema have impressed us with the value of this device for such a purpose. Since pulmonary emphysema is associated with increased functional residual capacity and expiratory difficulty, it would seem that correction of the pathomechanics would be aided more by use of IAPR than by the more commonly employed positive pressure breathing devices. Further work is in progress to document these impressions and to delineate the place of this respirator in the over-all management of patients with this disease.

Summary and Conclusions

A new mechanical respirator, operating on the principle of assisted expiration through intermittent abdominal pressure, has proved effective as a ventilatory aid in a group of 15 patients with respiratory paralysis. Adequate ventilation of all subjects was accomplished with less than 50 cm. H_2O applied to the abdomen with the subjects in a sitting position. Ventilation rose progessively as the subjects' trunks were raised from the recumbent to the sitting position and, similarly, as the abdominal pressure was increased. The respirator has been found to be a valuable adjunct to other respiratory aids in permitting rehabilitation activities without hypoxia. For some activities it is the respirator of choice. Preliminary observations in patients with pulmonary emphysema suggest that this new respirator may have a definite place in the over-all management of this disease.

COLD ADAPTATION.—The natives who volunteered for the tests were all young males of the Pitjandjara tribe of the arid, semi-desert country of central Australia. Around the native settlement at Areyonga they wore clothing, usually shirt and trousers and, sometimes, boots. They informed us through the superintendent, who spoke their language, that usually they removed their clothing at night, using it as a pillow, and invariably they did this while out hunting. . . . We were here interested in analyzing the response of natives and ourselves sleeping "proper bush", i.e. nude between fires in the native way. The natives were therefore asked to arrange the windbreak and fires for the night according to their accustomed manner. The men then stripped and lay down either singly or back to back between the fires. They took care of stoking the fires themselves and this occurred some 3-10 times during the night. They lay motionless between stokings and apparently slept well, frequently snoring. . . . The metabolic and thermal response was investigated by measuring oxygen consumption and rectal, skin and environmental temperatures throughout the night. . . . The great heating of the skin towards the fire and the considerable cooling towards the shadow, i.e. the sky or another man, are very striking. Skin temperatures were regularly found to be lower in the natives than in the whites. . . . Natives sleeping 'proper bush' and stoking the fires at their own volition often had skin temperatures in the shadows as low as 12-15°C and, facing the fire, sometimes exceeding 45°C. . . . Such temperatures, which must be regarded as of normal occurrence in the natives, are painful to white men. In contrast, measurements in our own regular sleeping gear showed that all our skin temperatures, including that of the foot, remained above 33°C throughout the night. With a much greater latitude of tolerance to chilling and relatively few interruptions for fire tending, the native can rest and sleep through cold nights.—P. F. Scholander, H. T. Hammel, J. S. Hart, D. H. LeMessurier, and J. Steen, Cold Adaptation in Australian Aborigines, *Journal of Applied Physiology*, September, 1958.

CLINICAL NOTES

SHORT DISTANCE RADIO TELEMETERING OF PHYSIOLOGICAL INFORMATION

F. Lowell Dunn, M.D.
and
Harold G. Beenken, E.E., Omaha

Current development of transistors and electronic circuitry provides an opportunity for further advances in the development of portable equipment for studying physiological function in ambulant and working subjects.[1] With encouragement, about four years ago we began the design of a portable transmitting and recording system. Objectives were as follows: the transmitter should be compact and not over 2 lb. in weight; the system should transmit the frequencies encountered in most physiological studies, i. e., 0 to 1,000 cps; the system should transmit and record more than one channel simultaneously; the transmitter should transmit all channels requiring only the addition of suitable transducers and preamplifiers for the various types of physiological information desired; and the system should be operable by persons without radio engineering experience. Electrocardiographic transmission was selected for the first design because it represents an important band of physiological frequencies and we were familiar with the circuit problems. We wish to describe here the present model. Electronic details will be described elsewhere.[2]

After a number of preliminary assemblies a system was constructed transmitting at 540 kilocycles per second. The weight was over 2 lb. because of the necessity of using vacuum tubes in several stages requiring filament and high-voltage batteries. A study of Federal Communications Commission (FCC) data showed that the 540-kilocycle region had a high noise level in such buildings as hospitals and that this noise level was too high for reliable operation under the FCC low-power radiation rule. In 1954 it was not obvious how rapidly transistors would improve, but by 1956 noise levels were down, greater uniformity in production was being achieved, and operation was successful in megacycle ranges. The advantages of operation in the megacycle range are great. At 100,000,000 cps, equipment components would be smaller and battery consumption much less, there would be the advantage of using frequency modulation for transmission, and the design of a multichannel assembly would be simplified.

Transmitting System

Figure 1 shows a block diagram of the transmitting system. The patient is connected to the electrocardiogram preamplifier by means of three electrodes properly placed to get the desired recording. The electrode signals 2 to 3 mv. maximum with an average of 6,000 ohms source impedance and is amplified by the electrocardiogram preamplifier to such a level that the 3-mv. signal results in 90 to 95% amplitude modulation of audio frequency. The audio oscillator is tuned to the carrier frequency of the channel involved. In this unit it is 2,100 cps. Design considerations are for multichannel operation, up to a maximum of 10 channels. The carrier frequencies of the first six channels are 600, 1,350, 2,100, 2,850, 3,600, and 4,350 cps. These channels will have a band width of 170 cps at the 1-db. points, 250 cps at the 3-db. points, and 275 cps at the 6-db. points. The next four channels will have nominal band widths of 1,000 cps each. The exact carrier frequencies of these four channels have not been determined but will be between 6,000 and 15,000 cps. The amplitude modulation of the audio frequency also takes place in this block.

The amplitude modulation (AM) signal is then amplified in the next block to proper power level to frequency modulate the following stage. AM signals from other channels will be combined in this stage.

The last block in the transmitting system includes the radio frequency oscillator oscillating at 104 megacycles per second and the circuitry for fre-

---

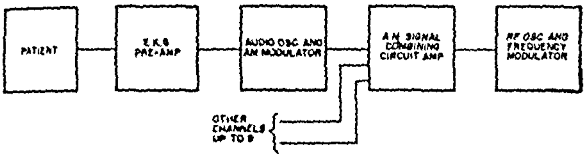
quency modulation (FM) of this frequency with the combined AM signals from the channels.

The system of AM-FM is being used. FM of the radio frequency was chosen because of its inherent advantages over AM in signal to noise ratio and because the field of transistors has developed enough to allow operation at the very high frequencies where FM is desirable. Double side band AM of the audio channel frequency is used because a simple detector can be used without supplying a demodulating frequency that has to be kept at the same frequency as the channel frequency. Small drifts of the channel frequency do no harm as long as the frequency is satisfactorily inside the pass band of the receive band pass filter.



PATIENT
E.K.G. PRE-AMP
AUDIO OSC AND AM MODULATOR
A.M. SIGNAL COMBINING CIRCUIT AMP
RF OSC AND FREQUENCY MODULATOR
OTHER CHANNELS UP TO 8

Fig. 1.—Block diagram of transmitting system.

A block diagram of the receiving system is shown in figure 2. The receiving antenna is a four-element beam with a driven element, reflector, and two directors. The FM receiver can be any good receiver covering the frequency band involved.

The output of the receiver is impedance matched by means of an L pad, if required, to the 600 ohm input of the band pass filters. The channels are separated by means of these receive band pass filters. One receive band pass filter is used for one-channel operation, two for two-channel operation, etc. The output of the receive band pass filter is connected to a conventional diode detector. The output of the detector is connected to a low pass filter. This low pass filter passes the desired detected intelligence from direct current to 300 cps and attenuates audio carrier frequencies and harmonics due to detection by more than 50 db. The output of the low pass filter is terminated in its characteristic impedance of 10,000 ohms and can be connected to almost any recorder of greater than 10,000 ohms input resistance and greater sensitivity than 1 volt full scale. Other recorders could possibly be used with proper circuit matching pads. In electrocardiogram transmission, enough loss is inserted in the receive circuit so that a conventional electrocardiogram recorder can be used.

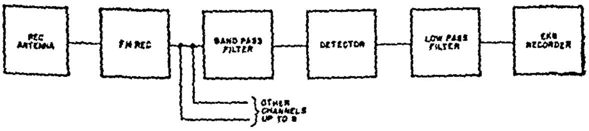


Fig. 2.—Block diagram of receiving system.

Miniaturization of the transmitting system has been accomplished to the extent that no large circuit components are required. The power supply requirements are very low because the transmitter is completely transistorized. Our test model used mostly standard-size circuit components as a convenience in making changes dictated by test results. Use of miniature and subminiature components and assemblies would greatly reduce the size of the system. Figure 3 shows the single-channel electrocardiogram model. Battery current for the preamplifier and audio oscillator is approximately 2 ma. and for the radio frequency circuit 3 ma. Battery life is approximately 100 hours. An antenna was not used. To be nondirectional, an antenna would have to extend several feet above the head. Aside from being conspicuous it would interfere with walking through doorways. Radiation is obtained direct from the tuned oscillator circuit, i. e., two turns 1¼-in. diameter of no. 14 tinned wire, which can be seen in figure 3. This provides a transmitter which is essentially nondirectional,

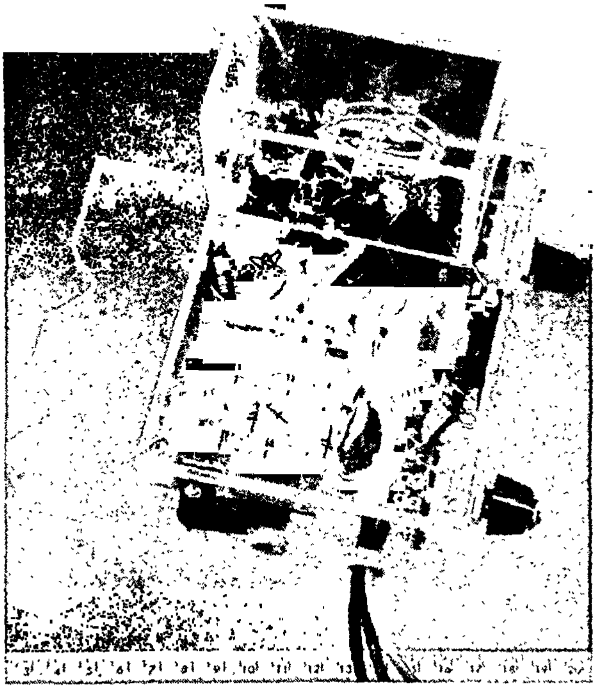

Fig. 3.—Complete transmitter with single channel for electrocardiogram transmission, with band width of 250 cycles and time constant of 4 seconds operating at AM carrier frequency of 2,100 cps and FM frequency of 104 megacycles per second.

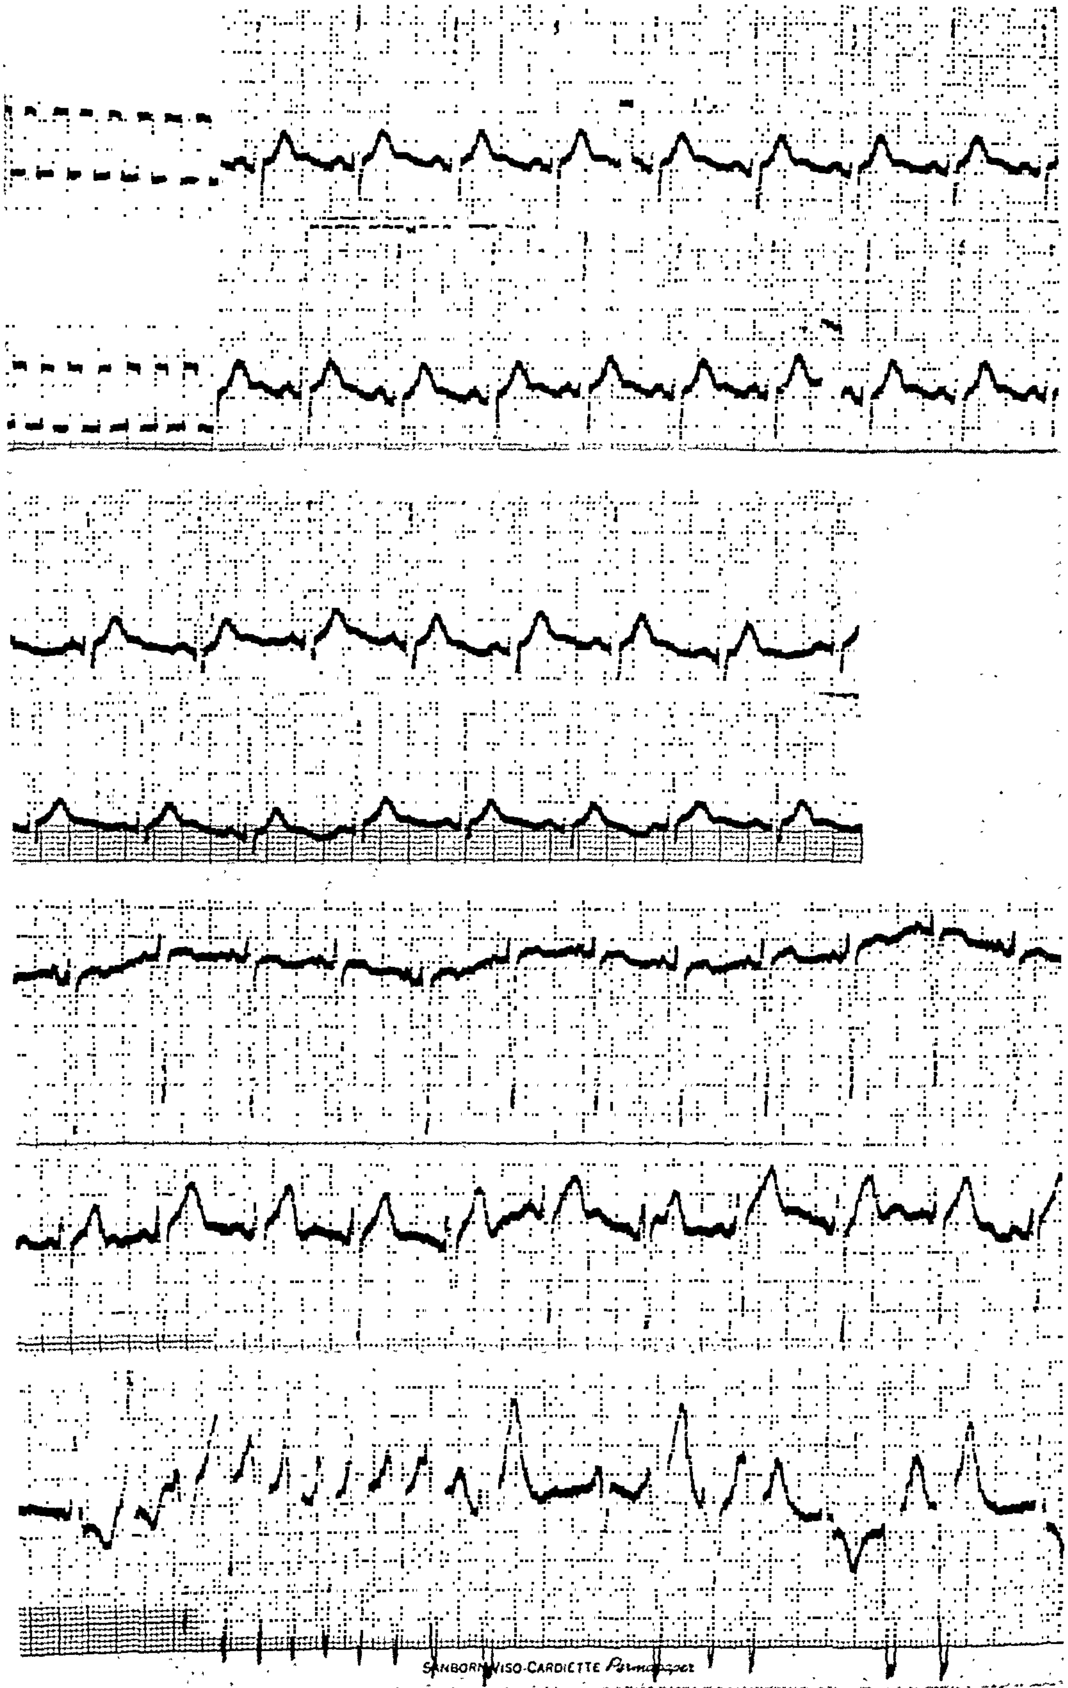

Fig. 4.—*Top tracing*, standardization, 1 mv., and electrocardiogram from direct-writing electrocardiograph. *Second tracing*, standardization and electrocardiogram from same subject with use of radio transmitter and recorded by same electrocardiograph. *Third tracing*, transmitter 100 ft. from receiver, fastened to subject's back, which was toward receiver. *Fourth tracing*, subject facing receiver. *Fifth tracing*, subject walking in corridor. *Sixth tracing*, subject walking on treadmill. *Seventh tracing*, short run of ventricular tachycardia while subject was walking on treadmill.

and calibration is maintained over the working distance. Operating distance is about 200 ft. indoors and over 500 ft. outdoors. Larger transistors, which should be available to us soon, will increase the working distance to a half mile, which appears to be a maximum for projects presently contemplated. The transmitter is stable in operation, does not require any field adjustments, and is not affected by shaking. During construction the transmitter was tested and adjusted for uniformity of operation over the range of 70 to 90 F. The electrocardiogram preamplifier works satisfactorily over the range of 60 to 106 F.

The one-channel model reported here was used for electrocardiogram transmission. This meant that the preamplifier had to amplify signals of 0.1 to 3 mv. in the presence of skin potentials of a possible amplitude of 50 to 100 mv., have a time constant of 4 seconds, have at least 200,000 ohms input impedance, maintain a steady base line, and have adequate rejection of inphase signals.[3]

Clinical Use

Figure 4 shows samples of records. A calibrating signal of 1 mv. is provided in the preamplifier. Transmission of records is without loss of fidelity, and the time constant of 4 seconds is sufficient to transmit the slower changes in the electrocardiogram without loss of amplitude.[3] Tracings 3 and 4, taken with the subject standing 100 ft. from the receiver, show that position does not affect fidelity of the transmission. Tracings 5 and 6 were taken with the subjects walking in the hall and on a treadmill. The front electrode is in V_3 position, and the back electrode is at the same level and ½ in. to the right of the midline. Tracing 7 shows the sudden onset of a ventricular tachycardia in a young man. The immediate recording permitted diagnosis and cessation of the exercise promptly before his severe type of attack developed.

By the use of available transducers and the construction of proper preamplifiers, the transmitting system can be applied to counting, temperature, pressure curves, curves requiring base-line stability and calibration, and electrical and mechanical sensing. A few of the applications that have been discussed are as follows: electrocardiograph monitoring of exercise tests; combination of two electrocardiograms to produce a vector that will give maximum sensitivity to T-wave changes as an index of anoxia during exercise testing; electrocardiogram monitoring during conferences where strain patterns are introduced; rectal temperature and/or electrocardiogram in a tractor operator working in a field; electroencephalographic monitoring in ward or conference; electromyographic or myographic multichannel recording for diagnosis or for study of phases of coordination in retraining; pressure measurements from various locations of the foot and shoe during walking; and monitoring electrocardiograms in operating or recovery room without connecting wires.

Several other features should be mentioned. Modern medical practice often utilizes formidable masses of instrumentation both in the ward and in the operating room. The stability and ease of operation of this transmitter offers the possibility of eliminating a few of the wires draped around the subject and at the same time notably reduces possible explosion hazards due to the very low voltages used and the completeness of shielding possible. This isolation of the transmitter makes it much less susceptible to stray fields, artifacts, and noise.

Summary

A completely transistorized radio transmitter and receiving system operates at 104 megacycles per second. The weight is under 2 lb., without the use of miniature parts. Design is for transmission of up to 10 channels with band widths of 150 to 1,000 cps. The channel reported has a carrier frequency of 2,100 cps and was tested for electrocardiographic recording. Satisfactory calibrated records were obtained with subjects walking and on the treadmill.

CORTICOSTEROID TREATMENT OF TRANSFUSION REACTION FROM INCOMPATIBLE BLOOD OF ABO TYPE

REPORT OF A CASE

George G. Spellman, M.D., Sioux City, Iowa

Blood transfusions have become commonplace in the practice of medicine; mortality from them is approximately the same as mortality from appendectomies. Some reactions do occur, however, for various reasons, and their treatment requires prompt recognition of the type of reaction and immediate therapy. Transfusion reactions are of four types: pyrogenic, manifested by fever, chilly sensations, nausea, vomiting, and headache; allergic, manifested by urticaria and sometimes wheezing; reaction to the plasma of the blood, manifested by chills, fever, and muscular pains but no hemolysis; and finally the dreaded hemolytic reaction which is sometimes fatal.[1]

The hemolytic reaction is an antigen-antibody reaction due to blood group incompatibilities. It begins suddenly, soon after the transfusion is started. The patient becomes restless and complains of back pain, chills, fever, nausea, vomiting, and precordial oppression. The condition may progress rapidly into shock. Hemoglobinemia and hemoglobinuria appear almost immediately. Impairment of renal function usually ensues, and the patient most frequently dies from this cause. A fatal bleeding tendency may also develop.

The treatment of the patient with hemolytic reaction has heretofore consisted primarily in stopping the blood transfusion and instituting supportive measures to protect the kidney and to treat the eventual lower nephron nephrosis. Antibiotics are indicated to combat infection which may increase the breakdown of protein, and electrolytes must be carefully balanced. In spite of the fact that there are many reports of the effectiveness of ACTH and cortisone in the treatment of acquired hemolytic anemia [2] or hemolytic disease of the fetus and newborn (erythroblastosis fetalis),[3] there have been few reports in the literature of the use of these agents in the treatment of patients with transfusion reaction. The report of a patient so treated follows.

A 57-year-old woman underwent repair of a cystocele and rectocele and excision of the cervical stump on Aug. 6, 1957. She was discharged from the hospital on Aug. 15 in good condition. Shortly after going home she began to bleed slightly. On Aug. 21 she bled profusely and was readmitted to the hospital in a state of shock. Her hemoglobin level was 8 Gm. per 100 cc. She was given a transfusion on the morning of admission, without reaction, but continued to bleed slightly. She was given another transfusion on the evening of admission and again there were no ill-effects.

On the morning of Aug. 22, at 10:20 a.m., another transfusion was begun. Almost immediately she began to complain of not feeling well. The rate of transfusion was slowed. The patient complained of nausea and aching and had a severe shaking chill. Her temperature reached 103.4 F. (29.6 C). The transfusion was stopped at 10:55 a.m. after almost 200 cc. had been given. A check on the blood showed that she had received type A blood and her blood was type O, Rh positive. Through a laboratory error, the wrong bottle of blood had been given her. Within one-half hour after the start of the transfusion her blood pressure had dropped to 70/50 mm. Hg from 110/60. She had a backache and was in critical condition. ACTH, 40 units in 1,000 cc. of 5% glucose in water, was started intravenously. She was also given 100 mg. of hydrocortisone sodium succinate (Solu-Cortef) intravenously and 50 mg. of cortisone intramuscularly. Intramuscular cortisone therapy was maintained in full dosages as well as ACTH gel.

Frequent laboratory studies were done on the patient. Urinalysis on Aug. 23, 1957, showed a faint trace of albumin and six to eight white blood cells per high-power field, but there were no red blood cells and no evidence of hemoglobinuria. Results of van den Bergh's test remained normal throughout. Repeated urinalyses and blood studies showed no evidence of hemolysis. Her urea nitrogen level rose slightly from 18 mg. per 100 cc. on Aug. 22 to 25 mg. per 100 cc. on Aug. 27. Her blood cell count rose steadily from a hemoglobin concentration of 8.8 Gm. and 2,700,000 erythrocytes per 100 cc. on Aug. 24 to 10 Gm. of hemoglobin and 3,340,000 erythrocytes on Sept. 2. By Sept. 2, her urea nitrogen level had dropped to 16 mg. per 100 cc. Her urine at times showed a few red blood cells and a few white blood cells but a Foley catheter was in place during this time and some of these may have been due to irritation. The patient had a good volume of urine throughout this time. She recovered and has remained well.

Summary

The literature contains many reports of the effectiveness of ACTH and cortisone in the treatment of hemolytic anemias of the acquired type or Rh incompatibilities. Corticosteroid therapy has been effective in the treatment of patients with hemolytic disease of the fetus and newborn (erythroblastosis fetalis); there are a number of reports of prevention of this disease in utero by administration of corticosteroids to the mother.[3b]

In a case of transfusion reaction ACTH and cortisone apparently blocked the hemolysis expected from an incompatible blood transfusion. Administration of corticosteroids in these medical emergencies should be added to the present program of treatment.

SPONTANEOUS HEMOPNEUMOTHORAX IN A HEMOPHILIAC

John F. Burke, M.D.
and
Edwin W. Salzman, M.D., Boston

Despite the diversity of hemorrhagic complications encountered in patients with hemophilia, bleeding within the chest is uncommon. In 1943, review of the early literature by Freedman and associates [1] revealed only two cases of hemorrhagic disease complicated by hemothorax; neither patient was a hemophiliac. These authors reported a 22-year-old man with a familial history and laboratory studies characteristic of hemophilia, whose spontaneous hemothorax was treated successfully by repeated thoracenteses and "numerous small transfusions." A similar case had been reported by Pendergrass and Neuhauser [2] the year before. In 1957, Kay and Kupfer [3] reported a spontaneous hemothorax in a proved hemophiliac successfully treated by thoracenteses and infusions of antihemophilic globulin.

In 1953, in the Polish literature, Juszczynski [4] reported a stab wound of the chest successfully treated by thoracotomy in a presumed hemophiliac. The response of this patient to stored bank blood suggests that this was actually a case of Christmas disease and not classic hemophilia.

In a search of the literature, no previous case of spontaneous hemopneumothorax complicating hemophilia was found. Since the management of the mechanical problems of a pneumothorax complicated by intrapleural bleeding in a hemophiliac has not to our knowledge been discussed in the literature, it seems worthwhile to present the following case report.

Report of a Case

A 27-year-old man entered the emergency ward of the Massachusetts General Hospital, Boston, at 9 p.m. on July 25, 1957, shortly after the onset of left thorax and arm pain which developed while he was getting out of an automobile.

Physical examination on admission showed an acutely dyspneic, well-developed young man with a left pneumothorax. X-ray examination of the chest on admission showed 75% collapse of the left lung and a small amount of fluid at the base. Thoracentesis in the second anterior interspace was performed, with removal of 1,500 cc. of air under slight positive pressure. This procedure completely relieved the patient's dyspnea. Physical examination showed reexpansion of the left lung.

During the night his dyspnea returned. Physical examination again revealed a left pneumothorax with shift of the mediastinum to the right and fluid at the left base. Aspiration of 1,500 cc. of air from his chest was done, and near normal breath sounds returned and his dyspnea disappeared.

On admission a history suggestive of hemophilia had been given, and an infusion of fresh frozen plasma was begun. At this time his hemoglobin level was 15.5 Gm.%, white blood cell count 8,300 per cubic millimeter with a normal differential, bleeding time 7 minutes,[5] and clotting time 16 minutes.[6] The number of platelets appeared normal on the smear. Stool guaiac examination and urinalysis gave negative results.

By morning he again began to feel short of breath, and x-ray examination showed a total collapse of the left lung with fluid present to the level of the sixth interspace posteriorly and a shift of the mediastinum to the right. Because of the continued signs of tension, a catheter was placed through the eighth interspace in the posterior axillary line under 10 cm. of water negative pressure. Aspiration of 1,000 cc. of blood was done. There was a moderate pulmonary air leak, as judged by the steady aspiration of air from the chest. Laboratory studies showed a hemoglobin level of 15.0 Gm.%, platelet count of 343,000 per cubic millimeter,[7] normal clot retraction with no lysis, prothrombin time 100%,[8] and prothrombin consumption 84%.[10] However, at

---

From the Department of Surgery, Harvard Medical School, and the Surgical Services, Massachusetts General Hospital.

the time these tests were done he had received 300 cc. of fresh frozen plasma and 500 cc. of fresh blood.

The patient had bled easily after minor trauma since childhood. A tonsillectomy at the age of 7 years was followed by profuse hemorrhage requiring packing and transfusion. A subsequent tooth extraction and a cheek laceration had each required transfusion. He had been studied in 1937 at the Boston City Hospital, where a diagnosis of hemophilia had been made. His maternal grandfather was a "bleeder" and had died of hemorrhage. His brother had also bled severely after minor lacerations. There was no history of abnormal bleeding in his mother or other members of the immediate family.

Despite catheter drainage the lung remained completely collapsed. A second catheter was placed in the second anterior interspace in the midclavicular line the evening of the first day. During the first 24 hours 3,000 cc. of blood was drained from his chest tube and there was evidence of a continued pulmonary air leak. During this period he had been on a regimen of 100 cc. of fresh frozen plasma per hour, quantitative replacement of blood loss by fresh blood transfusions, and administration of Vitamin K, ascorbic acid, and antibiotics. Although his clotting time was normal, he continued to bleed. In the second 24 hours 2,500 cc. of blood was drained from his chest despite replacement with fresh blood and fresh frozen plasma. Treatment with 120 mg. of prednisone in four divided doses was begun. X-ray examination showed the mediastinum to be shifted to the right and his lung totally collapsed despite the two catheters.

On the third hospital day the bleeding, as measured by the chest catheter drainage, slowed and by the fourth day had stopped. The fresh frozen plasma infusion was reduced to 100 cc. every three hours, and the upper tube was removed. On the sixth day he was comfortable. Clotting time was three and one-half minutes. The remaining catheter was removed. The amount of fresh frozen plasma given was reduced to 500 ml. per day.

On the ninth day purulent drainage from the lower catheter wound appeared, his temperature rose to 103 F (39.4 C), and it was apparent that he had an empyema. Culture showed Staphylococcus pyogenes var. aureus sensitive to chloramphenicol (Chloromycetin) and erythromycin. Treatment with this combination of antibiotics controlled the systemic infection, and the empyema drained spontaneously through the previous stab wound in the lower left chest. He was discharged on Aug. 27, 1957, with a chronic draining empyema.

He was readmitted on Sept. 7, 1957, because of persistence of fever, weight loss, and malaise. A catheter was inserted into the left chest, but adequate drainage could not be established. Rib resection, which had been previously rejected because of the danger of bleeding, was now elected. In order to be sure that bleeding could be controlled, a test incision was made through the superficial tissue down to the eighth rib in the postaxillary line after 800 cc. of fresh frozen plasma had been given. This was closed, and postoperative bleeding was not a problem. On the following day a 4-cm. segment of the eighth rib was excised by reopening the test incision after a second priming dose of 800 cc. of fresh frozen plasma. Free open drainage of the left thorax was established. Over the next two weeks his temperature declined, although his general status was unimproved, and he was sent home on Oct. 18, 1957, for convalescence.

In the succeeding six weeks he continued to lose weight and to run a low-grade fever at home; he was admitted on Nov. 29, 1957, for reevaluation. On admission there was marked muscle atrophy of the left chest. He appeared chronically ill and wasted. There was a bronchopleurocutaneous fistula. Culture of the empyema drainage showed Staph. pyogenes var. aureus and Bacillus pyocyaneus. The left lung was collapsed, and there was marked thickening of the parietal and visceral pleura by x-ray. Laboratory studies showed the following findings: hemoglobin level 11 Gm.%, white blood cell count 13,000 per cubic millimeter, platelets 627,000 per cubic millimeter, clotting time 20 minutes, one-stage prothrombin time 100%, prothrombin consumption 75%, thromboplastin generation 25%,[11] antihemophilic globulin level 40%,[12] Christmas factor level 80%, factor V level 120%,[14] factor VII level 50%,[15] and fibrinogen level 400 mg. %.[16] His clotting defect was readily corrected in vitro by the addition of fresh normal plasma but not by the addition of plasma from a patient with classic hemophilia.

Because of his progressive downhill course and bronchopleurocutaneous fistula, it was felt that early death was inevitable unless the septic process could be controlled. Conservative measures, which had been previously elected because of his bleeding defect, had failed and it appeared that only decortication, reexpansion of the lung, and closure of the fistula would reverse the decline.

Since coagulation studies showed him to have a relatively mild degree of hemophilia and the surgically induced bleeding during the rib resection for drainage of his empyema had been easily controlled, it was felt probable that his bleeding disorder could be managed with fresh frozen plasma.

In preparation for operation he was given 800 cc. of fresh frozen plasma during the induction of anesthesia. This raised his thromboplastin generation, antihemophilic globulin level, and Christmas factor level each to 100% of normal. A visceral and parietal decortication with good expansion of the lung was carried out through a left lateral thoracotomy in the fifth interspace. The bronchopleural fistula was found in the posterior segment of the upper lobe, where dense adhesions held the atelectatic segment to the chest wall. This was easily closed. Bleeding was meticulously controlled with fine ligatures where possible and with the electrocautery on surfaces where ligatures could not be used. Bleeding during the procedure was not excessive, and all losses were immediately replaced with fresh whole blood.

He received 2,000 cc. of fresh blood the day of operation. In the first two postoperative days his chest tubes drained 1,800 cc. of blood, which was replaced with transfusions of fresh blood. In addition, he received 100 cc. of fresh frozen plasma per hour. By the third day his hemoglobin level was 9 Gm.%. He received an additional 1,200 cc. of fresh blood. It appeared that he was accumulating a large, clotted, left hemothorax. The mediastinum shifted to the right and the chest catheters ceased to drain. He became dyspneic, and by the fifth postoperative day his respiratory status had become so precarious that the incision in the left side of the chest was reopened with the patient under cyclopropane anesthesia and 2,300 cc. of clotted blood was evacuated. No specific bleeding point could be identified. While the chest was being closed, heart action suddenly ceased. Manual systole was immediately instituted with resumption of normal sinus rhythm after a minute of massage. The incision was then closed, whereupon he developed ventricular fibrillation. Electrical defibrillation was performed, but manual systole for 1 hour and 48 minutes failed to restore spontaneous heart action.

Comment

The hazards of major operations in patients with hemophilia have been emphasized by Craddock and co-workers[17] and MacFarlane and associates[18] and need not be reiterated here. In the reported case, even though the clotting disorder as assessed in the laboratory was mild, major operation was not performed until it was evident that the patient would surely die without it. Despite the fact that the laboratory tests indicated that the hematological defect was corrected by the administration of fresh frozen plasma and fresh whole blood, it is obvious that adequate hemostasis was not achieved by their administration, even in the doses used.

The treatment of tension pneumothorax was complicated here by the hemorrhagic disorder. Multiple needle aspirations of the chest, which are least likely to cause further bleeding in a hemophiliac, were inadequate to restore a negative intrapleural pressure in this case because of the persistent pulmonary air leak. The immediate respiratory problem was solved by trocar thoracotomy and constant suction. The bleeding was controlled by massive doses of fresh frozen plasma. Prednisone was also used, but its contribution is difficult to evaluate.

The patient's recovery was shortly interrupted by the development of a bronchopleural fistula and an empyema. Because of the persistence of these, despite rib resection and drainage, and because the bleeding defect as measured in the laboratory could be corrected by giving the patient fresh frozen plasma, closure of the fistula and reexpansion of the lung by decortication were elected.

The unavailability of concentrated antihemophilic globulin from animal or human sources led us to use fresh blood and fresh frozen plasma as replacement therapy. The inadequacy of these agents in major hemorrhage has been described by others[18] and was demonstrated by this patient during his early hospitalization and in the period after thoracotomy. It appears that the replacement measures used here can control bleeding in minor procedures, such as trocar thoracotomy or rib resection for empyema drainage. Even in large doses, fresh frozen plasma and fresh blood are inadequate, however, to manage hemophilia in surgery of the magnitude of pulmonary decortication.

It is also apparent that assessment of the level of antihemophilic globulin by the thromboplastin generation test may be deceptive in gauging the severity and likelihood of hemorrhagic complications in hemophilia. A suggestion of the general efficiency of hematological control in minor operations may be gained by a test incision while giving antihemophilic therapy. A precise prediction of the patient's ability to undergo a major operation, however, may be impossible at the present time.

Summary

A case of spontaneous hemopneumothorax occurred in a patient with classic hemophilia. Minor operations—trocar thoracotomy and rib resection—were successfully performed with the use of fresh frozen plasma. The inadequacy of using such conventional replacement therapy for an operation of the magnitude of pulmonary decortication is evident. Preoperative assessment of the operative risk in hemophiliacs by present techniques may be unreliable.

Dr. Joseph McGovern of the Children's Medical Service performed the clotting studies reported.

COMMITTEE ON COSMETICS

Report to the Committee

The persistent trend toward the incorporation of pharmacologically active ingredients into cosmetics has caused growing concern among the medical profession. One example of this tendency is evident in the increasing interest among cosmetic manufacturers in the possible applications and sales potential of the incorporation of antibiotics into cosmetics. Medical experience provides considerable evidence of the health implications in the widespread, prolonged, or indiscriminate use of antibiotics. Therefore, the Committee has authorized the publication of the following report on the inclusion of antibiotics in products intended for nontherapeutic purposes. VERONICA LUCEY CONLEY, PH.D., *Secretary.*

INCLUSION OF ANTIBIOTICS IN COSMETIC PREPARATIONS

Carl T. Nelson, M.D.
and
Marion B. Sulzberger, M.D., New York

There seems to be essential agreement that antibiotics generally useful in the treatment of systemic infections should not be used in cosmetics. The risk of sensitization of cosmetic users to such antibiotics could be dangerous. Moreover, and perhaps even more important, the widespread use of cosmetics containing these antibiotics would be unwise because of the possible increased incidence of acquired microbial resistance to such drugs. Therefore, under no circumstances should the antibiotics used in cosmetics include agents of this type.

It has been proposed that agents such as bacitracin, neomycin, polymyxin, and tyrothricin be permitted in cosmetic preparations. Through their use, antimicrobial action would be secured against a wide spectrum of micro-organisms, and the antibiotics used would rarely be required later on for the treatment of systemic infections.

At the present time, the foregoing antibiotics seem to have a relatively low potential for sensitization when applied to the skin. By and large, they are believed not to be potent sensitizers or irritants. Nevertheless, it is not unreasonable to assume that the frequency of sensitization and/or irritation might increase if these agents were applied indiscriminately over a prolonged period of time in an ever-mounting number of individuals. Their use in cosmetics would certainly augment the number of people at risk. By the same token, the time and duration of exposure would inevitably be increased because cosmetics may be applied one or more times each day. We do not have sufficient evidence at this point to state categorically that these compounds cause very little irritation or sensitization of the skin. As time goes on and as the use of these antibiotics becomes more widespread, we may expect that more instances of allergic contact dermatitis, as well as other forms of sensitization and irritation due to these agents, will be reported. Evidence that this may be so is already contained in publications by Baer and Ludwig,[1] Epstein,[2] Sidi, Hincky, and Longueville,[3] and others, including our own observations of isolated cases of allergic contact dermatitis due to neomycin and streptomycin.

In addition, few data are available on the possible toxic effects of bacitracin, polymyxin B, neomycin, and tyrothricin after absorption through the skin. All of these antibiotics are known nephrotoxins. Before they can be legitimately used in cosmetics, evidence should be accumulated to indicate that their prolonged and widespread use on the skin will, in fact, not produce toxic effects of any sort. The burden of proof that such toxicity does not exist rests with those who would include these agents in cosmetics.

Development of Microbial Resistance

A third point at issue in this matter is the possibility that the indiscriminate use of these antibiotics may induce the development of microbial resistance to these agents. Although in vitro studies have indicated that the development of bacterial resistance to these antibiotics is not common, this

---

From the Department of Dermatology, College of Physicians and Surgeons, Columbia University and the Dermatology Service, Presbyterian Hospital (Dr. Nelson) and from the Department of Dermatology and Syphilology, New York University Post-Graduate Medical School and the Skin and Cancer Unit of the University Hospital (Dr. Sulzberger).

fact should not produce a false sense of security regarding their indiscriminate use. The major result of the widespread use of these antibiotics may be expected to be the elimination of the more sensitive bacterial flora and its replacement by one that is resistant to the action of these agents.

An example of the evidence of this effect can be found in the experience of one of our own institutions. Data accumulated at the Presbyterian Hospital in New York City during the past few years showed an increase in the proportion of antibiotic-resistant micro-organisms isolated from cutaneous infections acquired by the ward population. At the same time, similar infections seen in the outpatient departments of the hospital showed no analogous increase in antibiotic-resistant isolates. Since there was little evidence to indicate that the hospital ward infections were caused by micro-organisms that developed resistance to antibiotics during the patients' hospital stay, the presumption was that these infections were caused by antibiotic-resistant organisms, mainly because their antibiotic-susceptible competitors had been eliminated from the hospital ward environment. It seems, therefore, that the widespread use of antibiotics within a hospital is associated with a disappearance of antibiotic-susceptible organisms, and the strains that remain to produce infections are those that probably were inherently resistant to antibiotics from the beginning. In this connection, it is of interest that the increased percentage of antibiotic-resistant strains of bacteria isolated in the laboratories of Presbyterian Hospital in recent years correlates closely with the increasing extent to which the various antibiotics have been used in the hospital during this period of time.

Although such findings do not conclusively prove that extensive usage is the main factor concerned in changes in resistance of skin bacteria to antibiotics, the inference is that, as antibiotics are used over longer periods of time and with a larger population at risk, the microbial flora found in the environment of that population will be made up more and more of strains of micro-organisms inherently resistant to the antibiotics. Under these conditions, antibiotic-susceptible strains will tend to be eliminated, and it makes little practical difference whether the resistant replacements left free to cause troublesome infections are those that acquire resistance to the antibiotics by their own devices or are those that survive because they are inherently resistant to these agents.

Insofar as we know, there is also no evidence that constant degerming of the skin (except to reduce axillary odors), such as would presumably occur with the widespread use of antibiotics in cosmetics, is necessarily always or even frequently desirable. Evidence has already been presented to show that the widespread topical use of neomycin may increase the number of patients who develop moniliasis as a complication of their therapy.[4] Those who would include such antibiotics as bacitracin, tyrothricin, neomycin, and polymyxin in cosmetics should be prepared to show that their widespread use would not result in an increased incidence of infections due to micro-organisms that are resistant to these agents. Except for the deodorant action of such agents in reducing axillary odors, their incorporation in cosmetics has not been proved to be of specific value, and their widespread use in cosmetics could well represent an increased risk to general public health as well as to certain hypersensitive individuals.

ADVANTAGES OF GIVING UP SMOKING.—The main advantages of not smoking were wisely summed up by Lord Morton of Henryton in a letter to The Times ten years ago. He had been a heavy smoker for 35 years.... His motive in writing to The Times was not to set forth anti-smoking propaganda, but merely to console people who felt they could no longer afford to smoke. . . . "He who gives up smoking will find," he wrote, "that (1) his general health steadily improves; (2) he plays his favorite game with greater skill and less fatigue; (3) his enjoyment of food and drink is keener; (4) his sense of smell is more acute—this has its disadvantages, but the advantages outweigh them; (5) he no longer has that tiresome cough and his mouth feels cleaner; (6) he saves a lot of money; (7) he has a joyous feeling of independence while others are seeking for cigarettes and matches; (8) he enjoys plays and concerts more because he is not longing for a smoke."—J. H. Doggart, M.D., Smoking as a Factor in Visual Disturbance, *The Practitioner*, February, 1959.

ORIGIN OF THE TERM "INTERNAL MEDICINE"

GUEST EDITORIAL

Arthur L. Bloomfield, M.D.

RECENTLY Keefer[1] and Rhoads[2] discussed the origin and meaning of the term "internal medicine." They did not bring out, however, what was well known at the turn of the century when German medicine dominated American medical thought, that "internal medicine" is simply a translation of the German *innere Medizin.* We must therefore seek the meaning of the term internal medicine by ferreting out the origin of the German *innere Medizin.*

In looking over the important German treatises on medicine one finds that until the last quarter of the 19th century they were all designated as textbooks of pathology and therapy without any suggestion of the words internal medicine. Felix Niemeyer, in his "Lehrbuch der speciellen Pathologie und Therapie" (Berlin, 1859), says "One will readily discover everywhere [in the book] the scientific striving to apply the newer physiology to the explanation of the pathological and therapeutic facts, and to deduce the symptoms of the illnesses as a necessary consequence." The concept of "internal" medicine was, however, not yet emphasized. Ten years later, in the preface of Niemeyer's seventh edition, Berlin, 1868, there was still no mention of "internal medicine."

But 15 years later the title of Adolf Strümpell's "Lehrbuch der speciellen Pathologie und Therapie der inneren Krankheiten (Leipzig, 1883) has added "of internal diseases," and in the preface he declares that he has tried to bring out "the established facts with reference to internal diseases." What, then, is meant by "internal disease"? All branches of surgery are obviously excluded and the term is clearly used in contrast to external disease, namely, disorders of the skin. Much was made in Germany of dermatology at this time, as witness the numerous treatises of four or more volumes dealing with the subject. Because of the frequent skin lesions of syphilis the dermatologist included syphilis in his domain, and thence extended it to venereal disease in general. There was therefore much for him to do. All this, however, was excluded from the *innere Krankheiten* in distinction to the external diseases—dermatology. It was of course only a short step from internal diseases to the generic term internal medicine and from this to internist as a designation for him who practiced internal medicine.

By 1882 the term was in common use in Germany. So the transactions of the first congress of internal medicine are entitled without further comment "Verhandlungen des Congresses für innere Medicin" (Wiesbaden, 1882). The important journal, *Centralblatt für klinische Medicin* which first appeared in 1881, suddenly changed its name in 1894 to *Centralblatt für innere Medicin.* In the first number of this volume the editor states that this change was made to do away with the misunderstanding that the journal dealt only with purely clinical matters. He said, "our purpose is to give a survey of everything which the world-literature offers in the domain of 'internal medicine.'" Apropos of this point of view J. von Mering in his textbook of internal medicine, "Lehrbuch der inneren Medizin" (Jena, 1901), says "The domain of internal medicine has by the accretion of the most various experimental disciplines reached such a scope that one man can no longer be fully authoritative in all its branches. Only the investigator is competent to critically sift the endless accumulation of detail so that the best can be offered to students and general practitioners." So quite early there was applied to internal medicine a wider concept than that of the simple clinical description of disease; the physiological and chemical basis was included. This concept of "internal medicine" was repeatedly stated by the Germans. The preface to Mohr and Staehelin's monumental "Handbuch der inneren Medizin" (Berlin, 1911) opens as follows: "This book is built up above all on a pathologic-physiological basis." In the second edition (1925) they said "our leading thought is to present 'internal medicine' even more thoroughly on a pathologic-physiologic basis."

From the Department of Medicine, Stanford University School of Medicine, San Francisco.

[2] Rhoads, P. S.: Internal Medicine and Training of Internists, A. M. A. Arch. Int. Med. **102**:515 (Oct.) 1958.

It is clear then how the concept of "internal medicine" developed in Germany so as to comprise nonsurgical diseases, exclusive of dermatology; the term also implied a scientific attitude quite different from that of the *practischen Arzt*, the general doctor.

In tracing the use of the term in the United States, one must remember the immense influence of German medicine on ours before World War I. Doctors in huge numbers went to Germany to study; microscopes, instruments, and laboratory glassware were imported from Germany; one did not do a research, one did an *Arbeit*; one did not speak of laboratory assistants, one spoke of the *Diener*. Small wonder then that many expressions were simply translations of the German. The word, "Archives" is simply a translation of German *Archiv*. The English use of the term, however, is absurd, since it is a place to keep records and presumably should be used for dead storage and not for new material. So dominated by German thought was American medicine that the *Archives of Internal Medicine* was launched in 1908 without a word of prefatory material. Forchheimer's well-known book, "The Prophylaxis and Treatment of Internal Diseases" (New York, 1906), evidently was copied from the German *innere Krankheiten*. So too we have through the years such textbooks as Musser's "Internal Medicine" (Philadelphia, 1932) and Yater's "Fundamentals of Internal Medicine" (New York, 1954). The American Medical Association nevertheless did not replace its section on the Practice of Medicine by one on Internal Medicine until 1945.

In Britain things are different. Although much closer to Germany, British medicine shows little evidence of German influence. To my knowledge, the term "internal medicine" is not used in England. There is no textbook on "internal medicine" nor is there a journal with "internal medicine" as part of the title.

So whatever implications may now be attributed to it, the origin of the term "internal medicine" is quite clear.

NOISE OF JET ENGINES MAY BE A HAZARD

While progress in aviation provides greater speed in travel and comfort, it introduces a noise hazard which if not recognized and understood can cause deafness. Until recently the noise of jet engines has been a problem associated primarily with the military air bases and experimental airfields of plane manufacturers. Since commercial aviation has entered the age of jet powered aircraft, the noise of jets will have some effect on many other persons, such as travelers, crew members, and ground personnel. Probably several million persons living very near airports will notice differences between the noise of jet aircraft and that of conventional propeller airplanes. Although these persons may complain of the noise, they are not likely to be deafened because the sound intensity will be lower than the hazardous levels.

Several thousand persons in the United States work at airports. The so-called ramp personnel, those who work outside and inside the terminal buildings and the operators in maintenance areas of airports, will at times be working in dangerous sound levels. In an article "Airports and Jet Noise,"[1] Miller, Beranek, and Kryter show that the sound-pressure levels 100 ft. from the center of the four-jet engine array during warm-ups and ramp operations may be as much as 110 db. This condition is not desirable, especially if a person is exposed to such noise intensity for long periods. If a person, attendant, or passenger should get nearer than 100 ft. the noise can cause injury to the ear.[2] The ramp attendants and service crews are required to use noise reduction ear plugs and ear muffs during the engine run-ups and other ground operations. When the jet engines are being serviced they are placed in acoustically treated test cells to protect the mechanics and to reduce the noise radiated to nearby residential areas. Reliable evidence indicates that passengers emplaning or deplaning will not be subject to hearing trauma. The occupants in the fuselage of the plane are also protected. If, however, a passenger or a helper should step too close to the exhaust of the jet engines, an injury within the ear could occur. Because people vary in their response to loud noises, the maximum safe noise-intensity level cannot be stated as a single over-all value. If a worker or passenger comes near the exhaust stream of a jet engine, as much as 120 db. in the 150 to 300 cycles per second band can be impressed on an unprotected ear. This is a dangerous sound intensity level.[2] Prolonged exposure to noise (in the 300 to 600 or 600 to 1,200 cycles per second bands) of the order of 85 db. suggests initiation of a noise-exposure control program and tests of hearing for those exposed to this noise.[3]

All physicians might well inform themselves about this hearing hazard which is an unfortunate by-product of progress in air travel.

ORGANIZATION SECTION

THE EMBLEM OF THE AMERICAN MEDICAL ASSOCIATION

George M. Fister, M.D., Ogden, Utah
and
Thomas A. Hendricks, Chicago

The gods of mythology, Mercury, Aesculapius, Zeus, Pluto, and others probably will shudder in their retreats to find another human writing about the caduceus. Many humans probably will be equally amazed at this attempt to clarify a confusion that has developed out of the simplicity of the gods' intentions.

The gods' intentions were probably very clear, but between the ancient Greeks, the slightly less ancient Romans, and modern physicians there has developed ambiguity and uncertainty about the emblem of medicine.

By definition the word caduceus is a Latin adaptation from the Greek, a herald's wand (kerykeion), so the only meaning that the word caduceus has is a herald's wand. It has no connection with and carries no implication as a symbol of medicine. The herald who carried the wand (the caduceus) was the Greek god Hermes, also referred to as Mercury by the Romans.

Now Hermes was quite a god of classical mythology. He was a messenger, a herald of assemblies, the patron of commerce and peace, god of the rogues, and was undoubtedly a clever thief and could roll a wicked game of dice. It would seem that he didn't have enough to do, so he was further assigned the duty of conductor of the souls of the dead to the infernal regions. Hermes was no doubt as fluid and as slippery as the metal called mercury.

It was clear that no herald could function without a wand; to do so would have been as impractical as a chairman without a gavel. So Hermes immediately secured for himself a straight piece of an olive tree branch which was used as his wand. Thus the herald's wand, or caduceus, became one of Hermes' sacred possessions and he was apparently seldom seen without it.

The transition from the simple herald's wand to the more elaborate one with two snakes entwined was probably a gradual process, the addition of the snakes having been inspired by various legends plus the artists' interpretations. One legend relates that Hermes found two snakes fighting with each other. Hermes separated them with his olive branch wand, and by his kindness and the snakes' appreciation, they entwined themselves on his wand. Since Hermes was the messenger of the gods, two wings were added to the wand. These perhaps were to give him an increase in speed as he carried messages between friends and enemies. Thus Hermes, with the caduceus, became an emblem of commerce and perhaps neutrality.

A review of the literature permits and sustains the conclusion that the caduceus was simply the herald's wand of the winged god Hermes and was (and still should be) an emblem of all of his numerous duties, which did not include medicine.

According to Arnold [1] "All the meanings that we might attach to the caduceus can be summed up into one: vis; that it symbolizes the peaceful condition of business—the mercantile world as opposed to the military." Nevertheless, the U. S. Army Medical Corps and the U. S. Public Health Service continue to use the emblem of Hermes as their insignia. Probably its use here is justified, the intent being to portray the noncombatant character of the Medical Corps rather than as an emblem of the medical profession. In addition, the name caduceus is used almost universally, except in England, France, and Germany, as the emblem of the medical profession, an error that seems impossible of correction, but one that merits our best efforts to correct.

What then is the true emblem of the American Medical Association? Mythology relates that the Greek god Asklepios (Roman Aesculapius) [2] "studied the healing art and soon surpassed his teacher (Chiron) for his patients never died and he even succeeded in recalling the dead." Thus Asklepios was recognized by the Greeks as the god of medicine. Up to this point there is no apparent confusion between the two, Hermes and Asklepios, but for professional reasons Hermes carried a wand and Asklepios carried a staff and each began association with snakes. Complication of the significance of the symbols was the immediate result.

It is quite likely that Hermes and Asklepios sensing the need for a cane or walking stick, each unknown to the other, picked up a branch. Hermes made a straight olive wand, while Asklepios, being a little more rugged, made a knotty pine staff. Then along came the serpent! Like any physician, Asklepios was satisfied with and perhaps could afford only one, but Hermes, trained in the ways of commerce, sought out two snakes. The snakes in each case followed their natural instincts and entwined themselves about the sticks, one on Asklepios' staff and two on Hermes' wand.

Dr. Fister is a member of the Board of Trustees of the American Medical Association. Mr. Hendricks is Assistant to the Vice-President of the American Medical Association.

Thus we have two symbols, the caduceus, a wand entwined with two serpents, and the staff of Asklepios, entwined with one serpent. Asklepios was recognized by the Greeks as god of medicine. His fame spread throughout the Mediterranean area and he is reported to have had many medical sanctuaries, one of them in Epidaurus near Athens. Medical therapy in the era of Asklepian temple healing, extending into the third century A. D., must have been impressive if not always curative for Asklepios is reported to have had a large following, what we would now refer to as a successful practice.

Of course Asklepios, the Greek physician, did not wear a stethoscope, but he was always seen with his heavy staff. After his death he was worshiped as a god by the Greeks and Romans. Mythology relates the origin of his birth, and his death was the result of Pluto's jealousy, who had Jupiter destroy him with a thunder bolt, which seems to be a noisy way the ancients had of removing any competition. Many shrines were built in honor of Asklepios, the god of health, where was carried on a special type of healing by incubation.

Serpents since the time of Adam have been regarded with both fear and admiration. The snake's annual renewal of its skin, the graceful movements, its speed and destruction of its prey gradually led to sacred fascination and worship. To the snake was attributed rejuvenation, convalescence, wisdom, and long life. The serpents soon participated in certain rituals that were a definite part of the healing and curative procedures in the Asklepian temples. In recognition the staff of Asklepios became adorned with a serpent, a symbol of the medical profession.[3] "Reproduction of the statues of Asklepios usually show the physician standing in flowing toga with his right hand clasping the staff, along which a single snake makes its way upward." There need be no uncertainty about who is the mythical Greek and Roman god of the art of medicine. All legends, documents, and statues point definitely to Asklepios.

The American Medical Association in 1910 by official action of the House of Delegates adopted a report by a committee that had been appointed to revise the emblem of the Association. The Committee stated "The true ancestral symbol of the healing art is the knotty pine and the serpent of Asklepios. That the color of the new emblem should be scarlet and gold and the new emblem should be the knotty rod entwined with the serpent."[4] Much credit is due the Committee that was assigned to this task.

In retrospect of the error and looking forward to its correction, the following summation is presented: 1. The word caduceus means a herald's wand. It is a straight wand entwined with two serpents. It is not an emblem of the medical profession (although it has been adopted by medical and lay organizations). 2. Asklepios was a medical deity or legendary physician and he was enshrined as the mythical god of medicine. 3. The emblem of the American Medical Association is the knotty staff of Asklepios, entwined with one serpent. This is not a caduceus and should not be confused with one or referred to as one. 4. The American Medical Association should conduct an educational program to correct the grossly negligent use of the word caduceus. State, county, and local medical societies should assist the program. All physicians should be made acquainted with the emblem of the American Medical Association, which is the staff of Asklepios (Roman Aesculapius).

REPORT OF JOINT COMMISSION ON ACCREDITATION OF HOSPITALS

The following items from the March, 1959, issue of the bulletin of the Joint Commission on Accreditation of Hospitals (660 N. Rush St., Chicago; Kenneth B. Babcock, M.D., director) are presented for the information they contain that will be of interest to many physicians.—Ed.

Report of Activities of Accreditation Commission for 1958

As of Dec. 31, 1958, there were 3,896 hospitals on the Joint Commission on Accreditation of Hospitals list (3,523 in the United States, 2 in the Canal Zone, 22 in Puerto Rico, 16 in Hawaii, 323 in Canada, and 9 in other countries). In 1958, the cost of a survey averaged $175.14. This figure does not include the sums spent by the American College of Surgeons and the American Hospital Association for overhead expenses of maintaining field staffs. If these were included, the cost per survey would be much more. Because of this monetary cost and the loss of precious time, the Commission is reluctant to cancel or postpone a scheduled survey. It is rare that another survey can be substituted for a cancellation, so time is lost and expenses go on. It sometimes happens that a hospital seeking accreditation for the first time cancels its survey when it is scheduled. The reason given is that the hospital is not yet ready and asks for more time to prepare for the survey. This procedure is costly and should be avoided. A request for accreditation should not be made until the hospital is willing to have a survey. The Certificate of Accreditation is being revised. This is necessary because of the resignation of the Canadian Medical Association. This is taking longer than anticipated, so the certificate for those hospitals accredited since Jan. 1, 1959, will be delayed.

Canada Launches Its Own Accreditation Program

On Jan. 1, 1959, the Canadian Council on Hospital Accreditation assumed the responsibility of accrediting hospitals in Canada. To give its full support to this program, the Canadian Medical Association resigned its membership in the Joint Commission on Accreditation of Hospitals. Motivated by an admirable spirit of national independence, the organization of the Canadian Council marks the culmination of several years of working and planning. Its members are the Canadian Hospital Association, the Canadian Medical Association, the Royal College of Physicians and Surgeons of Canada, and L'Association des Medecine de Langue Francaise du Canada. The aim of the program is the same as that of the Joint Commission on Accreditation of Hospitals, namely to help improve the quality of care rendered to patients in hospitals. There will be little or no departure from the program established by the American College of Surgeons and the Joint Commission on Accreditation of Hospitals. The standards for hospital accreditation of the Commission have been adopted by the Council as a basis for accreditation, as well as the survey procedures and report forms.

In order to give full support to the Canadian program, the Joint Commission on Accreditation of Hospitals has agreed to discontinue surveying and accrediting hospitals in Canada. This does not mean that the Commission is less interested in Canadian hospitals, but rather that the Commission will do everything possible to help the Canadian program succeed. Effective liaison will be established on both governing and administrative levels and efforts will be made to keep both programs as much alike as possible.

Representation on the Board of Commissioners Changed.—With the resignation of the Canadian Medical Association, the members of the Joint Commission on Accreditation of Hospitals voted that representation on the Board of Commissioners will be as follows:

American College of Physicians	3 votes
American College of Surgeons	3 votes
American Hospital Association	7 votes
American Medical Association	7 votes

GOVERNMENT SERVICES

ATOMIC ENERGY COMMISSION

Strontium-90 Fall-out.—There is nothing good about radioactive fall-out, and a constant effort is being made to reduce it to the minimum. A comprehensive document (Health and Safety Laboratory Report No. 42, Environmental Contamination from Weapons Tests) issued recently gives a nearly complete summary of U. S. data up till about last summer. It is available through the Department of Commerce Office of Technical Services. The high levels found sometimes in wheat, rice, other grasses, and various vegetables apparently are due to the fact that these plants pick up more fall-out from the rain falling directly on the leaves than from the roots and the soil. As a consequence their level depends more on the rate of fall-out than on the total accumulated fall-out in the soil, though there definitely is some pickup from the soil. The soil pickup, however, does not lead to the large fluctuations with seasons of the year that are found in these grasses and remains at lower values than the peaks that direct leaf pickup can attain during a period of intense nuclear weapons testing when the rate of fall-out can be particularly high for a short time. The amount of strontium-90 found in these products at times exceeds the levels considered acceptable for a steady diet. The general average food level, however, is the important figure and this is well below the maximum permissible level as given by the National Committee on Radiation Protection.

PUBLIC HEALTH SERVICE

Personal.—Dr. Robert C. Berson, vice-president of the University of Alabama Medical Center in Birmingham; Dr. E. Dwight Barnett, director of the Palo Alto–Stanford Hospital Center in Palo Alto, Calif.; Dr. Owen H. Wangensteen, chief of the Department of Surgery at the University of Minnesota Medical School, Minneapolis; and Dr. Thomas B. Turner, dean of the Medical Faculty of the Johns Hopkins School of Medicine in Baltimore, Md., have been appointed members of the National Advisory Council on Health Research Facilities. This is a reappointment for Dr. Turner. These doctors will advise and make recommendations to the surgeon general on matters relating to the federal program to strengthen the nation's capacity for medical research by constructing and equipping health research facilities.

MEDICAL NEWS

ALABAMA

Annual Session in Birmingham.—The Medical Association of the State of Alabama will hold its annual session in Birmingham April 9-11, with headquarters at the Dinkler-Tutwiler Hotel and with Dr. Edgar G. Givhan Jr., president of the association, presiding. Dr. S. Joseph Campbell, president, Jefferson County Medical Society, will present an address at the opening business meeting. The scientific program will include the following papers by out-of-state speakers:

Practical Shortcuts in Endocrinology, Diagnosis and Treatment, Dr. Peter H. Forsham, San Francisco.
The Diagnostic Value of Intravenous Cholangiography in Biliary Tract Disorders and Acute Abdominal Conditions, Dr. H. Stephen Weens, Atlanta, Ga.
Dietary Management of Children in Illness and in Health, Dr. Frederic G. Burke, Washington, D. C.
Pruritus Vulvæ, Dr. J. Donald Woodruff, Baltimore.
Prenatal Care—The Pale Pink Pill, Dr. Lawrence L. Hester Jr., Charleston, S. C.

The Jerome Cochran Lecture, "Somatopsychic Medicine," will be given April 10 by Dr. Sara M. Jordan, Boston. Dr. Louis M. Orr, Orlando, Fla., President-Elect, American Medical Association, will present "Medical Show Window of the World," and Mr. Leo Brown, Director, Communications Division, A. M. A., will speak on "The Second Mile." The presidential dinner-dance April 10 will be held at the Vestavia Country Club. For information, write Mr. W. A. Dozier Jr., 19 S. Jackson St., Montgomery 4, Ala., Executive Secretary.

CALIFORNIA

Study of Altitude Effects on Newborn.—To study effects of altitude on the hearts of newborn babies, Dr. Herbert N. Hultgren, head of Stanford's Cardiovascular Research Laboratory, made a trip to the Andes of South America under a grant from the National Heart Institute, U. S. Public Health Service. His headquarters were a hospital in La Oroya, Peru (altitude, 12,500 ft.). He carried a portable electrocardiograph, but the remainder of his equipment was furnished by the hospital at La Oroya. Dr. Hultgren plans to survey the potential for more extensive studies in the future.

CONNECTICUT

Annual State Meeting in Hamden.—The 167th annual meeting of the Connecticut State Medical Society will be held in Hamden High School, Hamden, April 28-30. The House of Delegates will meet April 28, with Dr. Thomas M. Feeney, Hartford, speaker of the house, presiding. Eleven sectional meetings of society and guest organizations are planned for the afternoon of April 29, with the annual dinner scheduled for that evening. The following papers will be presented by out-of-state speakers:

Multiple Antibiotics—Use and Abuse, Dr. Monroe J. Romansky, Washington, D. C.
Chemotherapy of Cancer in Children, Dr. Sidney Farber, Boston.
The Place of Serum Enzyme Determinations in Diagnosis and Treatment, Dr. John S. LaDue, New York City.
The Problem of Chronic Pancreatitis, Dr. Kenneth W. Warren, Boston.
The Use of Enzymes and Anti-Inflammatory Drugs in Surgical Disease, Dr. Eugene E. Cliffton, New York City.
Management of the Patient with Peripheral Obliterative Arterial Disease, Dr. Robert R. Linton, Brookline, Mass.
New Trends in Management of Diverticulitis, Dr. Alfred S. Frobese, Philadelphia.
Diagnosis of Vulvar Lesions, Dr. Mortimer D. Speiser, New York City.

A symposium, "Upper Gastrointestinal Hemorrhage," will be conducted the afternoon of April 30, with Dr. Paul D. Rosahn, New Britain, as chairman. For information write the Connecticut State Medical Society, 160 St. Ronan St., New Haven 11, Conn.

DISTRICT OF COLUMBIA

Dr. Head Admitted to Virginia Bar.—Dr. E. Murdock Head, of the surgical department, George Washington University Hospital, was recently admitted to the Virginia Bar and to practice before the Court of Appeals of Virginia. Dr. Head has, in addition to his M.D., degrees in dentistry and law. He is primarily interested in the teaching of legal-medicine.

Personal.—Dr. Edward D. Freis, associate professor of medicine, Georgetown University School of Medicine, was recently elected vice-chairman and chairman-elect of the Council on High Blood Pressure Research of the American Heart Association. ——Dr. Ralph M. Caulk was reelected president of the medical staff of the Washington Hospital Center at a meeting March 2.

Dr. Hufnagel Gives Kober Lecture.—Dr. Charles A. Hufnagel, professor of surgery and director of the Experimental Surgery Laboratory at the Georgetown University School of Medicine, delivered the 1959 Kober Lecture at Georgetown University

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

March 11 on "The Basic Concepts of Cardiac and Vascular Reconstruction." The Kober Lecture is provided for by the Kober Foundation of Georgetown, established by the late Dr. George M. Kober, dean of the university's Medical School from 1900 to 1929. Dr. Hufnagel was selected for this year's honor by the executive committee of the Medical Society of the District of Columbia.

FLORIDA

Civic Advisory Council for School Development.—Creation of a new advisory council of civic leaders for the School of Medicine of the University of Miami was authorized by the trustees of the university. Mr. Hoke Maroon, president, Merchants Bank of Miami, was named temporary chairman of the new group. In outlining the responsibilities of the new council, Jay F. W. Pearson, Ph.D., president of the university, indicated that it would concern itself with institutional and financial development of the medical school and all phases of the school's operation touching on the public interest. The council will be responsible to the university board of trustees and, when fully formed, will consist of 21 civic leaders, of whom about one-fourth will be physicians. Subcommittees of the council will deal with institutional development, financial development, and community relations.

IOWA

Annual Meeting in Des Moines.—The 1959 annual meeting of the Iowa State Medical Society, organized in 1850, will be held April 19-22 in the Veterans Memorial Auditorium, Des Moines. The president's address will be given by Dr. Walter D. Abbott, Des Moines. Dr. Ralph M. Kniseley, Castro Valley, Calif., will give the Arthur Erskine Memorial Lecture, "Important Non-Biological Contributions to Radioisotopic Diagnosis," April 21. Papers by out-of-state speakers include:

Aneurysms and Occlusive Disease of the Aorta and Peripheral Arteries: Experience with 2,000 Cases, Dr. George C. Morris Jr., Houston, Texas.
The Growth Pattern of Endometriosis, Dr. Roger B. Scott, Cleveland.
Respiratory Obstruction in Infants, Dr. F. Johnson Putney, Philadelphia.
Pediatric Urology, Dr. Robert Lich Jr., Louisville, Ky.
The Role of the Family Physician in Congenital Heart Disease, Dr. Patrick A. Ongley, Rochester, Minn.
Child Psychiatry for the General Practitioner, Dr. Reynold A. Jensen, Minneapolis.
Factitial Enteritis: An Unusual Cause of Intestinal Obstruction, Chronic Blood Loss, or Malabsorption Syndrome, Dr. William G. Sauer, Rochester, Minn.
The Place of Radioactive Isotopes in the Community Hospital, Dr. Frank R. Hendrickson, Chicago.
Problems Involved in the Treatment of Injuries to the Central Nervous System, Dr. Winchell M. Craig, Rochester, Minn.

Symposiums on "Exfoliative Cytology" and "Clinical Uses of Radioisotopes" are planned. Dr. Gunnar Gundersen, LaCrosse, Wis., President, American Medical Association, will present "Keeping the Paths Open" April 22. Scientific and technical exhibits and special meetings and dinners are arranged. The annual golf tournament will be held April 19, and the annual banquet, April 21, 7 p. m. The scientific program is acceptable to the American Academy of General Practice for 12 hours credit in category II.

KENTUCKY

Report on Diabetes Detection Drive.—One hundred eighty newly proved diabetics were discovered in Kentucky during the 1958 Diabetes Detection and Education Drive sponsored by the Kentucky State Medical Association in November, Dr. Robert J. Hoffmann, South Fort Mitchell, chairman, KSMA's Associate Committee on Diabetes, has announced. More than 90,500 Kentuckians in 72 counties were tested free of charge during the drive, according to the latest reports. Of these, 1,166 were found to have positive urine sugars. Final figures in the previous drive in 1957 indicated that 52,400 were tested in 83 counties and 137 newly proved diabetics were discovered.

LOUISIANA

Pediatric Meeting Features British Physician.—The Baton Rouge Pediatric Society announced that its June 16 quarterly meeting will consist of a program by Dr. Alan A. Moncrieff, chief of staff, The Hospital for Sick Children, Great Armond Street, London, England. The subject will be "Biochemistry and Mental Defects." For information write Dr. Francis M. Harris Jr., Secretary-Treasurer, Baton Rouge Pediatric Society, 1401 N. Foster Dr., Baton Rouge, La.

University News.—Dr. Alvar P. Wilska, of Helsinki, Finland, was appointed visiting professor of cell research at the Louisiana State University School of Medicine, New Orleans. Dr. Wilska will continue his work on the new electron microscope and inaugurate additional research projects in the department of anatomy with Frank N. Low, Ph.D., university professor and director of the electron microscope laboratory at Charity Hospital. A graduate of Helsinki University, Dr. Wilska received a degree of doctor of medicine and surgery in 1938 and served there as professor of physiology since 1944. He assumed his new duties Jan. 5.

MARYLAND

Annual Meeting in Baltimore.—The Medical and Chirurgical Faculty of Maryland will hold its 161st annual meeting April 15-17 at the Alcazar, Baltimore. Four illustrated papers will be given the afternoon of April 15:

Surgical Treatment of Aortic Valvular Disease, Dr. Charles A. Hufnagel, Washington, D. C.

Leukemia: Present Status, Dr. William Dameshek, Boston.
Surgical Treatment of Chronic Pancreatitis (J. M. T. Finney Fund Lecture), Dr. Ralph F. Bowers, Memphis, Tenn.
Atherogenesis and Lipid Metabolism, Dr. Charles F. Wilkinson Jr., New York City.

Dr. J. Sheldon Eastland, president of the faculty, will preside at a medicolegal symposium, "Whiplash Injuries: A Conference Between the Counsel and Medical Witnesses." The William Royal Stokes Memorial Lecture will be given by Dr. Horace L. Hodes, New York City, on "Staphylococcal Infections in the Antibiotic Era." Panel discussions on adrenocortical steroid therapy and on therapeutic uses of radioiodine are planned. The I. Ridgeway Trimble Fund Lecture, "Lesions of the Adrenal Glands (Illustrated)," will be presented by Dr. James T. Priestley, Rochester, Minn., April 16, to be followed by Dr. Edgar V. Allen, Rochester, Minn., presenting "The Natural History of Arteriosclerosis Obliterans (Illustrated)." Milton S. Eisenhower, president, Johns Hopkins University, Baltimore, will speak on "Our Partnership with Latin America" at a general meeting April 16, following the presidential dinner ($6.50). Round-table luncheon discussions (April 16) and exhibits are planned. Twelve hours category I credit will be given by the American Academy of General Practice for attendance. For information write Mr. John Sargeant, 1211 Cathedral St., Baltimore 1, Md., Executive Secretary.

MICHIGAN

Annual Conference on Aging.—"Designs for Retirement" will be the theme of the University of Michigan's 12th annual Conference on Aging June 22-24 in Ann Arbor. Over-all plan for the conference calls for five separate groups to meet simultaneously. Topics covered will include retirement health, retirement housing, retirement financing, retirement preparation, and uses of retirement. For information on the conference, write the Director, Wilma Donahue, Chairman, U-M Division of Gerontology, 151 Rackham Building, Ann Arbor, Mich. On June 24-26, immediately following the conference, the U-M will host a National Leadership Training Institute for the White House Conference on Aging. The institute is sponsored by the U. S. Department of Health, Education, and Welfare in cooperation with other interested federal agencies and the university.

Health Survey of Tecumseh.—Individual physical examinations for more than 8,000 residents of the Tecumseh area are scheduled as a result of a two-year grant of $280,000 given to The University of Michigan School of Public Health by the National Heart Institute, a branch of the U. S. Public Health Service. Researchers plan to make a complete health survey of each individual, but will seek special details on heart disease and related disorders. Each person will be notified of the results of his examination, and detailed medical reports will go to family physicians. The total body of data will be used to create a comprehensive picture of sickness and health in a single community. Dr. Thomas Francis Jr., who directed the nationwide field trials of the Salk polio vaccine, and Dr. Frederick H. Epstein are in charge of the survey. It is part of a broader community study directed by Dr. Robert J. M. Horton. All are faculty members of the University of Michigan School of Public Health.

MISSISSIPPI

New Department of Clinical Laboratory Science.—The University of Mississippi School of Medicine, Jackson, has created an independent department of clinical laboratory science, with Dr. Warren N. Bell as its chairman. The new department was formerly a division in the department of medicine, and Dr. Bell retains his appointment as an associate professor of medicine in addition to his new chairmanship.

MONTANA

Interim Meeting Held in Helena.—The 12th interim session of the Montana Medical Association was held April 3-4 in the Western Life Insurance Company Building, Helena, with Dr. Herbert T. Caraway, president of the association, presiding at the morning session April 3. Four panel discussions were held, with the following titles and moderators:

The Use and Disuse of ACTH and Adrenocorticoid Drugs, Dr. George B. LeTellier, Lewistown.
The Business Side of Your Profession, Mr. Norman McGinty, Billings.
Treatment of Acute Multiple Injuries, Dr. Warren H. Randall, Miles City.
Clinical Pathological Conference, Dr. Bernard J. Winter, Billings.

Three motion pictures were shown, and a tour of the State Board of Health Laboratory was held. At the banquet April 3, Dr. Everett H. Lindstrom, Helena, was the toastmaster.

NEW JERSEY

State Convention in Atlantic City.—The 193rd annual meeting of the Medical Society of New Jersey will be held April 25-29 in Haddon Hall, Atlantic City. An open "Discussion on Medical-Surgical Plan" will follow the Golden Merit Award ceremony April 25, and the House of Delegates will meet April 25, 26, and 27. Over 15 section meetings will be held April 28 and 29, with the following symposiums included:

Bronchial Asthma as an Occupational Hazard (Allergy).
Which of Your Patients Can Now Be Benefited by Cardiac Surgery? (Cardiovascular Diseases).

Diarrhea (Gastroenterology and Proctology).
The Prevention of Perinatal Loss (Obstetrics and Gynecology).
Certain Aspects of Eye Care in Children (Ophthalmology and Pediatrics).

At the general practice session, Drs. Milton Jabush, Lakewood, Abraham Weinberg, New York City, and Jacob H. Conn, Baltimore, will present "The Use of Hypnosis in Obstetrics," "Hypnosis in General Practice," and "Medical Hypnosis, Its Use and Abuse," respectively. Motion-picture theaters, special luncheons, and scientific and technical exhibits are planned. The Doctors' Chorus of the Essex County Medical Society will entertain at the dinner-dance April 28, 7 p. m. For information write the Medical Society of New Jersey, 315 W. State St., Trenton 8, N. J.

NEW YORK

Increase in Rabies in 1958.—The number of laboratory confirmed cases of rabies increased in the state in 1958. During the year, a total of 261 cases was reported to the Bureau of Epidemiology and Communicable Disease Control, New York State Department of Health, compared with 202 cases in 1957. Dr. Herman E. Hilleboe, state health commissioner, stated that the number was 55 less than that reported for 1956, however. Rabies was reported in 26 counties, being most prevalent in the following: Otsego, 65 cases; Delaware, 46; Chenango, 28; Madison, 23, and Steuben, 21. A total of 146 cases was reported in cattle. Other cases included dogs, 21; foxes, 56; cats, 21; raccoons, 7; sheep, 5, and horses and bats, two each. Dr. Hilleboe said that in recent years the reported incidence of rabies has been cyclic in nature with peaks of decreasing magnitude occurring every three or four years, starting with the peak incidence of 1,155 cases reported in 1946.

Study of Gamma Radiation.—An aerial survey to determine existing gamma radiation for an area of New York State, reportedly the first to be conducted by a state health department, was completed in the Hudson Valley area. Dr. Herman E. Hilleboe, State Health Commissioner, said establishment of existing gamma radiation levels makes it possible to compare preoperational and operational gamma levels for the area in the vicinity of atomic power plants. The survey was made in a helicopter provided by the Department of Defense. Five counties in the Lower Hudson River Drainage Basin are included in an environmental radiation survey being conducted by the State Health Department in cooperation with local health departments and the State Conservation Department. The others are Dutchess, Orange, Putnam, and Rockland. It is expected that by 1960, three nuclear reactors will be in operation in the Lower Hudson River Drainage Basin. The results of the aerial survey are being coordinated with the over-all sampling and spot checks in this area. When the preoperational aerial survey was made, the major contributing factors to gamma-ray emissions recorded included: cosmic radiation, natural radium and daughter products in the soil, rock, and vegetation, daughter products of radon in the air, natural potassium-ro in the soil, rock and vegetation, and particulate air matter and absorbed fission products on the ground resulting from the continuous fallout of fission products associated with nuclear test devices.

New York City

Physicians' Wives Hold Dinner-Dance.—Physicians and their wives of Greater New York are invited to attend a dinner-dance, sponsored by the Physicians' Wives League of Greater New York, to be held April 5 at the Waldorf Astoria Hotel. The league works to aid indigent physicians and their families. For information, write Mrs. Louis Wexler, 5 E. 76th St., New York 21.

Triplets Exceed Statistical Expectations.—More than three times as many triplets have been born in New York City so far this year as were statistically expected. There were 10 sets of triple births since the first of the year, Carl Erhardt, director of the Bureau of Records and Statistics, New York State Department of Health, announced March 8. Three sets of triplets were expected because vital statistic records show that triple births usually occur once in 9,900 deliveries. Since there have been 28,000 births so far this year, three sets of triplets was the statistical expectation. Instead of three sets among these 28,000 births, there were 10. Of the 30 babies in these 10 sets of triplets, 4 died at birth, 26 lived. Among the 167,775 births which occurred in 1958, there were 15 sets of triplets. Of these 45 infants, three died at birth, 42 lived. The triple births by boroughs were:

	1958	1959
Manhattan	4	1
Bronx	2	–
Brooklyn	4	5
Queens	5	2
Richmond	–	2
	15	10

Dr. Cooper Cited by Hospital.—Dr. Irving S. Cooper, director, department of neurosurgery, St. Barnabas Hospital for Chronic Diseases, Bronx, was honored by the hospital's board of managers at their 93rd annual meeting. Dr. Cooper, who developed the chemopallidectomy and who is professor of research surgery and director of the division of neuromuscular diseases at New York University Postgraduate Medical School, was awarded a citation by St. Barnabas Hospital in recognition of "distinguished leadership and outstanding contributions to medical science and to the professional services of St. Barnabas Hospital in the field of neurosurgical research and the treatment and alleviation of extrapyramidal disorders." As part of the ceremonies, a 27-minute sound film was shown.

Survey of Orthopedic Ailments in Children.—A youth health survey, in which 600 presumably normal children, age 10 to 14 years, from the Sen. Robert F. Wagner Junior High School in Manhattan were examined for unsuspected orthopedic ailments, was completed at the Hospital for Joint Diseases March 6 after 4½ months of work. The study was undertaken under the auspices of the Board of Education, the Department of Health, and the Hospital for Joint Diseases, a voluntary, nonprofit hospital located at 123rd Street and Madison Avenue. The hospital reported finding a considerable number of children with orthopedic difficulties of some kind, many of them previously unsuspected. Most of these ailments were minor, requiring corrective exercises, but a few serious conditions, resulting from "growth disturbances," were noted. All abnormalities found were promptly reported by the hospital to the principal of Robert F. Wagner Junior High School and to the Department of Health's Bureau of School Health, so that the parents could be alerted to bring their children under treatment. Robert F. Wagner Junior High School was chosen for the study by a joint hospital, Board of Education, and Department of Health committee because the students were deemed to constitute a representative cross-section of the city's school population in the 10-14 age bracket. The examinations have been conducted at the hospital's orthopedic clinic every Friday afternoon since Oct. 24, 1958, under the supervision of Dr. Michael S. Burman, attending orthopedic surgeon.

NORTH CAROLINA

Plan Building for Aging Study.—Plans for a building to house the Duke University Regional Center for the Study of Aging were announced by Duke President Hollis Edens. The structure will provide facilities for a multipronged attack on the problems of aging by researchers in medical, biological, social, and behavioral sciences. A construction grant of $388,000 was made to Duke by the National Institutes of Health, research center of the U. S. Public Health Service. Matching funds, now being sought by the university, will bring the total to $776,000. Preliminary plans call for the building to be erected in front of Duke Hospital where a parking area is now located near the hospital emergency entrance. The structure will be of modified Gothic architecture and will be faced with native North Carolina stone to match other West Campus buildings. Some 35,000 square feet of floor space will be provided by five stories, including a basement and sub-basement. Dr. Ewald W. Busse, Duke psychiatry department chairman, is head of the Regional Center for the Study of Aging. Representing a concentration of University-wide interest in this field, the center was established in July, 1957, with U. S. Public Health support which will total $1,500,000 over a five-year period. The Ford Foundation recently augmented these funds with a $200,000 grant for a sociological-economic study in aging.

OHIO

Dr. Griffith to Give Annual Lecture.—Dr. Harold R. Griffith, emeritus professor of anesthesia, McGill University, Canada, will be the guest speaker at the third annual Rolland J. Whitacre Memorial Address, sponsored by the Cleveland Society of Anesthesiologists. His talk, entitled "Adventures and Misadventures in Forty Years of Anaesthesiology," will be given at a dinner meeting at the Tudor Arms Hotel, Cleveland, the evening of May 20. For reservations, write Dr. Sidney W. Helperin, 20665 Centuryway, Maple Heights 37, Ohio.

Personal.—Dr. Robert J. Izant Jr. was appointed chief of the division of pediatric surgery in the department of surgery at University Hospitals of Cleveland. He also holds the appointment of assistant professor of surgery at Western Reserve University School of Medicine. He assumes the post formerly held by Dr. Edward Gerrish who has entered private practice in Minnesota. Prior to this appointment, Dr. Izant was the associate professor of surgery (pediatrics) at Ohio State University College of Medicine for three years.——Dr. Perry R. Ayres, Columbus, succeeded Dr. Jonathan Forman as editor of the *Ohio State Medical Journal.* Dr. Forman resigned in October. Dr. Ayres was editor and chief of *The Bulletin of the Columbus Academy of Medicine*, having served as associate editor of the publication from 1951 to 1957.

Annual Meeting in Columbus.—The annual meeting of the Ohio State Medical Association will be held April 21-24 in the Veterans Memorial Building, Columbus. The Ohio State Heart Association and the Ohio Division of the American Cancer Society are presenting the first day's programs. Ohio State University College of Medicine will present the final day's program in celebration of its 125th anniversary. Panel discussions to be held at the general sessions include "Treatment of Uterine Cancer," "Cancer of the Gastrointestinal Tract," and "Hypertension," moderated by Dr. Richard L. Meiling, Columbus, Dr. Robert M. Zollinger, Columbus, and Dr. Maurice A. Schnitker, Toledo, respectively. Specialty sections will be conducted April 22-23, including several combined programs. Over 30 guest participants are scheduled to speak, including Dr. Alejandro Aguirre, professor of pediatrics, National University of Mexico, Mexico,

D. F., who will present a paper the afternoon of April 22. Scientific and technical exhibits are planned. The annual banquet, to be held the evening of April 22, will feature the 42 members of the Montgomery County Medical Society Glee Club. For information write the Ohio State Medical Association, 79 E. State St., Columbus 15, Ohio.

PENNSYLVANIA

Philadelphia

Dr. Elliott Heads Hospital Department.—Dr. Frank A. Elliott, of London, arrived in Philadelphia to assume the post of neurologist to Pennsylvania Hospital and head of its department of neurology. This announcement coincided with Dr. Elliott's appointment as professor of clinical neurology, University of Pennsylvania School of Medicine. At Pennsylvania Hospital, Dr. Elliott will establish a neurological center to investigate the causes, treatment, and prevention of the common stroke and related neurological conditions. Funds for this project, amounting to $357,960, have been received as a grant from the John A. Hartford Foundation, Inc., of New York City, established by John A. Hartford, who, prior to his death in 1951, was president of the Great Atlantic and Pacific Tea Co. A native of South Africa, Dr. Elliott received his medical education at the University of Cape Town Medical School.

Open New Laboratory at Hahnemann.—On March 9 Dr. Charles S. Cameron, dean of Hahnemann Medical College, formally opened the 111-year-old institution's third new research laboratory in a year, the Laboratory for the Study of Lipids and Atherosclerosis. The new laboratory, under the direction of Dr. John J. Spitzer, associate professor of physiology, is another step in the planned expansion of Hahnemann's facilities for medical research, following the inauguration of the Institute for Biochemical Studies in Cancer in March, 1958, and the opening of the Cytology Laboratory in February. The Laboratory for the Study of Lipids and Atherosclerosis will chart the distinguishing characteristics between normal and diseased hearts with regard to lipid metabolism and the utilization of energy by the heart. The new facilities occupy an entire floor in a building adjoining the college. Dr. Spitzer has received more than a quarter-million dollars in research funds from the National Heart Institute, and additional support from the Southeastern Pennsylvania Heart Association, and the Smith, Kline, and French Foundation.

City Operates Tuberculosis Institute.—The City of Philadelphia has assumed responsibility for operation of the dispensaries of the Henry Phipps Institute of the University of Pennsylvania, as of March 2, Dr. Julius L. Wilson, director of the institute and professor of preventive medicine at the University, announced March 4. The institute is located at 7th and Lombard streets. Dr. Wilson said this development stemmed from a long period of increasing financial burden on the part of the institute to care for indigent tuberculosis patients. Dr. Wilson pointed out that the city had provided this service on a contractual basis at the Phipps Institute for the past five years. Two other tuberculosis clinics established by the Phipps Institute were long ago transferred to city control. The Henry Phipps Institute was founded in 1903 by the late Henry Phipps for the study, treatment, and prevention of tuberculosis. Present plans include moving its teaching and research activities from the present location to a new building to be constructed adjacent to the planned new West Philadelphia Health Center, which will be located at 43rd Street and Chester Avenue.

GENERAL

Railway Surgeons Meeting in Chicago.—The 71st annual meeting of the American Association of Railway Surgeons will be held April 16-18 at the Drake Hotel, Chicago. At the annual dinner April 17, 7:30 p. m., Dr. A. A. Nygood, Chicago, president of the association, will serve as toastmaster. On April 16, 2 p. m., Dr. David I. Abramson, Chicago, will moderate a symposium on "Peripheral Vascular Diseases," and the afternoon of April 17 Dr. Clifford J. Barborka, Chicago, will moderate a symposium, "Problems in the Management of Peptic Ulcer," as part of a gastroenterology program which includes as a participant Dr. Richard D. McKenna, Montreal, Canada. Surgical and medical movies are planned for the afternoon of April 18. For information write Dr. Chester C. Guy, Secretary, American Association of Railway Surgeons, 5800 Stony Island Ave., Chicago 37.

Orthopedic Meeting in Omaha.—The sixth annual meeting of the Mid-Central States Orthopedic Society will be held April 9-11 at the Town House, Omaha, under the presidency of Dr. Werner P. Jensen, who will open the meeting. Of the papers scheduled, the following will include invited authors:

Tetracycline Fluorescence in Bone Tumors, Dr. John E. McLeay, Omaha.

Experimental Studies and Practical Applications, Dr. Richard E. Ogborn.

Blood Volume Determination, Drs. Lawrence R. James, and L. Thomas Hood, Omaha.

Discussions will follow the papers. A program of tours, a bowling tournament, and other entertainment are arranged, including women's activities. For information write the Mid-Central States Orthopedic Society, 3244 E. Douglas, Wichita 8, Kan.

Anesthesiology Meeting in Birmingham.—The annual meeting of the Southern Society of Anesthesiologists will be held April 23-25 in the Dinkler-Tutwiler Hotel, Birmingham, Ala. Dr. Ralph Berson, dean and vice-president of medical affairs, University of Alabama, Birmingham, will open the meeting with an address. Over 20 papers are scheduled for presentation, and a movie, "Respiratory Resuscitation Techniques," will be shown the afternoon of April 24. A demonstration, "Pump for Extracorporeal Circulation with Possible Demonstration on Patients," will be presented by Drs. Frank A. Berg, Eugene C. Clark, and Champ Lyons, Birmingham. A round-table luncheon is planned for April 23. A program of ladies' entertainment is arranged. For information, write Dr. Ray T. Parmley, 529 N. Hillside St., Wichita 6, Kan., Secretary-Treasurer.

Meeting on Thoracic Surgery.—The 39th annual meeting of the American Association for Thoracic Surgery will be held April 21-23 in Los Angeles with headquarters at the Statler Hilton Hotel. The presidential address will be given April 22, 3 p. m., by Dr. Michael E. De Bakey, Houston, Texas. Forty-two papers are scheduled, including the following by invited participants:

An Improved Inexpensive Automatically Controlled Pump-Oxygenator, Drs. Adrian Kantrowitz, and Donald Abelson, Brooklyn.

An Externally Valved Hydraulic Cardiac Substitute, Drs. I. A. Breckler, R. L. Ginsberg, C. L. Portnoff, and Jack L. Bitterly, Encino, Calif.

A New Foam Plastic Arterial Prosthesis, Richard W. Hardy, Washington, D. C.

The Cause of Death Following Cardioangiography, Dr. Raymond C. Read, Minneapolis, Minn.

The banquet will be held at 7 p. m., April 22. For information write The American Association for Thoracic Surgery, 7730 Carondelet Ave., St. Louis 5, Dr. Hiram T. Langston, Secretary.

World Health Day.—World Health Day, April 7, marks the 11th anniversary of the World Health Organization. In recognition of mental illness as one of the major problems of world health, WHO chose "Mental Illness and Mental Health in the World of Today" as the theme for World Health Day 1959. Dr. M. G. Candau, director-general, World Health Organization, has stated that "in countries with well-developed health services, about half the total number of hospital beds are occupied by psychiatric cases. . . . This increase in mental ill health, involving whole populations, has fortunately been accompanied by rapid progress in the treatment and prevention of mental disease, and also by a better understanding for the psychological strains and stresses that gravely affect everyday behaviour and are not without influence on the well-being of mankind." According to Dr. Candau, World Health Day 1959 offers a suitable starting point in all countries "for a continuing crusade aimed at disseminating better knowledge of mental health problems, ensuring better care for the mentally unfit, and providing better chances for children to grow up in robust mental health."

Arteriosclerosis Society Merges with Heart Association.—The American Society for the Study of Arteriosclerosis merged with the American Heart Association, Dr. Francis L. Chamberlain, president of the association, has announced. The society became the Council on Arteriosclerosis of the American Heart Association. This brings to eight the number of councils now active in the heart association's program. The other councils cover clinical cardiology, cardiovascular surgery, circulation, high blood pressure, rheumatic fever and congenital heart disease, basic science, and community service and education. Since its establishment in 1947 by a group of investigators concerned with this phase of circulatory disease, the arteriosclerosis society has cooperated with the American Heart Association, which was reorganized as a voluntary health agency in 1948. In October, 1958, the society held its annual meeting to coincide with the heart association's annual scientific sessions in San Francisco and several joint programs were conducted. Following an invitation by the association to merge as a council, a large majority of the society's members voted in favor of the amalgamation. The new Council on Arteriosclerosis will hold a scientific session and a symposium as part of the heart association's 32nd annual scientific sessions in Philadelphia, Oct. 23-25, followed by an independent council meeting in November. Officers elected to the new Council on Arteriosclerosis are Dr. James C. Paterson, London, Ontario, Canada, chairman; Forrest E. Kandall, Ph.D., New York, vice-chairman; Dr. Otakar J. Pollak, Dover, Del., secretary; and Dr. Aaron Kellner, New York, program chairman.

Survey of Needs in Tropical Medicine.—The National Academy of Sciences–National Research Council has announced the undertaking of a major survey of needs in tropical medicine. The survey will be directed by Willard H. Wright, Ph.D., recently retired as chief of the Laboratory of Tropical Diseases, National Institutes of Health. Advocated for several years by the American Society of Tropical Medicine and Hygiene, the survey was proposed to the academy-research council by the Department of Defense on recommendation of the Armed Forces Epidemiological Board. Support has now been assured by the National Institutes of Health, the Department of the Army, and the Rockefeller Foundation. The survey will embrace the fields of infectious and parasitic diseases, veterinary medicine, and environmental hygiene. It will include surveys of disease problems in tropical and subtropical areas of significant importance to public health and to agricultural and industrial development; of funds expended for medical care and disease control; of financial support for research in medical and hygienic problems of the tropics; of fellowship opportunities, teaching programs, and training facilities; of career opportunities and incentives; of the impact of travel and migrations on tropical disease problems; of the importance of tropical medicine to the economy of the United States; and of projected manpower needs in terms of domestic and overseas requirements. On the basis of these data it will assess the need for domestic, foreign, and international measures to deal with the problems defined in the survey. The National Academy of Sciences–National Research Council is a private, nonprofit organization of scientists dedicated to the furtherance of science and its use for the general welfare. Its congressional charter, signed in 1863 by President Abraham Lincoln, calls upon the academy to advise the government, upon request, in all matters of scientific and technical interest.

Symposium on Myasthenia Gravis.—The Myasthenia Gravis Second International Symposium in conjunction with the American Academy of Neurology will meet at the Statler–Hilton Hotel, Los Angeles, April 18-19. Papers which include foreign authors are scheduled as follows:

The Neuromuscular Defect in Myasthenia: Electrophysiological and Histopathological Evidence, J. E. Desmedt, Brussels, Belgium.

Some Pathophysiological Mechanisms of Motor Disturbances in Myasthenia, N. I. Grashchenkov and L. B. Perelman, Moscow, U. S. S. R.

Electromyographic Studies in Myasthenia Gravis Correlated to Mechanical Events, Albrecht Struppler and Elizabeth Struppler, Munich, Germany.

A Study of Neuromuscular Transmission in 100 Cases of Myasthenia Gravis, H. C. Churchill–Davidson and A. T. Richardson, London, England.

The Isolation of Quaternary Nitrogen Compounds from Extracts of Thymus Glands, Peter T. Nowell and Andrew Wilson, Liverpool, England.

Some Pharmacologic Properties of Gamma Butyrobetaine, E. A. Hosein, Emma Ottolenghi, and Sheila Dorfman, Montreal, Quebec, Canada.

Recent Work on the Mechanism of Myasthenia Gravis, with Special Reference to the Metabolism of Progesterone, Raymond Greene and I. Schrire, London, England.

The Incidence of Myasthenia Gravis in a Sample Population, George Pennington and Andrew Wilson, Liverpool, England.

Evaluation of Keynes' Large Series of Thymectomies, R. T. Ross, Winnipeg, Canada.

Physiological Concept of the Central Action of the Carotid Sinus, Pierre Passouant, Montpellier, France.

Carotid Sinus Denervation, Andre Thevenard, Paris, France.

A panel, "What Is and What Is Not Myasthenia Gravis?" (Lee M. Eaton Memorial Panel), will be held the morning of April 19, with Dr. Robert B. Aird, San Francisco, as chairman. For information write the Myasthenia Gravis Foundation, Inc., 155 E. 53rd St., New York 10. The program is co-sponsored by the foundation and the National Institute of Neurological Diseases and Blindness.

FOREIGN

Congress on Plastic Surgery in London.—The International Congress of Plastic Surgery, organized by the British Association of Plastic Surgeons, will be held at the Royal College of Surgeons of England, London, July 12-17, under the patronage of His Royal Highness the Duke of Edinburgh. The scientific program will include papers grouped to form symposiums under the following headings:

Surgery of Congenital Deformities
The Surgery of Skin Cancer
Industrial Injuries to the Hand
Trauma of the Face
Cosmetic Surgery
Anesthesia in Plastic Surgery
Research Projects

A Trade Exhibition is being organized at the Royal College of Surgeons. The social program will include the president's reception, a performance at the Royal Opera House, and a banquet on the last night of the congress. For information write Mr. David Matthews, Organizing Secretary, International Congress on Plastic Surgery, c/o Institute of Child Health, Hospital for Sick Children, Great Ormond St., London, W. C. 1, England.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part II only, April 21-22; Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world, Sept. 22. Final date for filing application is June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Written.* Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

Alaska:* On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Examination.* Phoenix, Apr. 15-17. *Reciprocity and Endorsement.* Phoenix, April 18. Exec. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, June 11-12. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* San Francisco, June 15-18; Los Angeles, Aug. 17-20; Sacramento, October 19-22. *Oral.* San Francisco, June 13; Los Angeles, August 15; San Francisco, November 14. *Oral and Clinical.* San Francisco, June 14; Los Angeles, August 16; San Francisco, Nov. 15. Sec., Dr. Louis E. Jones, Room 536, 1020 N Street, Sacramento.

Delaware: *Examination.* Dover, July 14-16. *Endorsement.* Dover, July 23. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

District of Columbia:* *Written.* Washington, June 8-9. Final date for filing application is May 1. Sec., Dr. Daniel Leo Finucane, 1740 Massachusetts Ave., N. W., Washington.

Florida:* *Examination.* Miami Beach, June 21-23. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, June 10-11. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subiect to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Hawaii: *Written.* Honolulu, July 13-14. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: *Examination and Endorsement.* Boise, July 13. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination.* Chicago, April 6-9. *Reciprocity.* Chicago, April 10. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June 17-19. Exec. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Iowa:* *Examination.* Iowa City, June 15-17. Exec. Sec., Mr. Ronald V. Saf, State Office Bldg., Des Moines 19.

Kansas:* *Examination and Endorsement.* Kansas City, June. Sec., Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, June 8-10. Sec., Dr. Russell E. Teague, 620 South Third St., Louisville 2.

Maryland: *Examination.* Baltimore, June 23-26. Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Ann Arbor and Detroit, June 8-10. Sec., Dr. E. C. Swanson, 118 Stevens T. Mason Bldg., West Michigan Ave., Lansing 8.

Minneapolis:* *Examination.* Minneapolis, April 21-23. *Reciprocity.* Minneapolis, April 23. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Examination and Reciprocity.* Jackson, June 22-24. Sec., Dr. A. L. Gray, Old Capitol, Jackson 13.

Missouri: *Reciprocity.* Kansas City, April 6. *Examination.* St. Louis, May 29-30. Exec. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Montana: *Examination and Reciprocity.* Helena, April 7. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June 15-17. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

New Jersey: *Examination.* Trenton, June 16-19. Sec., Dr. Royal A. Schaaf, 28 West State St., Trenton 8.

New Mexico:* *Examination and Reciprocity.* Sante Fe, May 18-19. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* New York, Rochester, Syracuse, Buffalo and Albany, June 23-26. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Endorsement.* Asheville, May 4. *Written. Examination and Endorsement.* Raleigh, June 15-18. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination and Reciprocity.* Grand Forks, July 8-11. Sec., Dr. C. J. Glaspel, Box 228, Grafton.

Ohio: *Endorsement.* Columbus, April 7. *Examination.* Columbus, June 18-20. Sec., Dr. H. M. Platter, 21 West Broad St., Columbus 15.

Oklahoma:* *Examination.* Oklahoma City, June 2-3. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Written.* Portland, Apr. 17-19. Ex. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination and Endorsement.* Philadelphia and Pittsburgh, July 1-3. Sec., Mrs. Margaret G. Steiner, Box 911 Harrisburg.

Rhode Island:* *Examination.* Providence, April 2-3. Administrator of Professional Education, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Reciprocity.* Columbia, May 12; *Examination.* Columbia, June 23-24. Sec., Dr. H. E. Jervey, Jr., 1829 Blanding St., Columbia.

South Dakota:* *Examination.* Sioux Falls, Aug. 25-26. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Texas:* *Examination and Reciprocity.* Fort Worth, June 22-24. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination and Reciprocity.* Salt Lake City, July 810. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Virginia: *Examination.* Richmond, June 18-20. *Endorsement.* Richmond, June 17. Address: Board of Medical Examiners, 631 First St., S. W., Roanoke.

Washington:* *Examination.* Seattle, July 13-15. Administrator, Mr. Thomas A. Carter, Capitol Bldg., Olympia.

West Virginia: *Reciprocity and Endorsement.* Charleston, April 13. *Examination.* Charleston, June. Sec., Dr. Newman H. Syer, State Office Bldg., No. 3, Charleston 5.

Wisconsin:* *Written.* Milwaukee, July 14-16. *Reciprocity.* Madison, April 17 and Milwaukee, July 15. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.

Wyoming: *Examination and Reciprocity.* Cheyenne, June 1. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arkansas: *Examination.* Little Rock, May 4-5. Sec., Dr. S. C. Dellinger, University of Arkansas, Fayetteville.

Colorado: *Examination.* Denver, May 6-7. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: *Examination.* New Haven, June 6. Exec. Asst. Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, May 18-19. Address: Mr. Paul Foley, Deputy Director, 1740 Massachusetts Ave., N. W., Washington.

Florida: *Examination.* Miami, June 6. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

Iowa: *Examination.* Des Moines, April 14. Sec., Dr. Elmer W. Hertel, Wartburg College, Waverly.

Kansas: *Examination.* Kansas City, June 2-3. Sec., Dr. L. C. Heckert, Pittsburg.

Michigan: *Examination.* Ann Arbor and Detroit, May 8-9. Sec., Mrs. Anne Baker, West Michigan Ave., 116 Stevens T. Mason Bldg., Lansing.

Minnesota: *Examination.* Minneapolis, April 7-8. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, May 5-6. Director, Mr. R. K. Kirkman, Bureau of Examining Boards, 1009 State Capitol Bldg., Lincoln.

New Mexico: *Examination.* Santa Fe, April 19. Sec., Mrs. Marguerite Cantrell, P. O. Box 1522, Santa Fe.

South Dakota: *Examination.* Vermillion, June 5-6. Sec., Dr. Gregg M. Evans, 310 East 15th St., Yankton.

Texas: *Examination.* Austin, Galveston, Houston, Apr. 17-18. Certificates issued by reciprocity and waiver on the first and fifteenth of each month. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Washington: *Examination.* Seattle, July 8-9. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

Wisconsin: *Examination.* Madison, April 4. Final date for filing application was March 27. Milwaukee, June 6. Final date for final application is May 29. Sec., Mr. W. H. Barber, 621 Ransom St., Ripon.

---

*Basic Science Certificate required.

DEATHS

Ansanelli, Francis Cornelius, New York City; Georgetown University School of Medicine, Washington, D. C., 1932; specialist certified by the American Board of Psychiatry and Neurology; member of the American Academy of Neurology; veteran of World War II; associated with the New York Eye and Ear Infirmary, Bronx Eye and Ear Infirmary, and the Lenox Hill Hospital; consulting neurologist for the U. S. Public Health Service; died in the Neurological Institute Dec. 5, aged 53.

Bellamy, Robert Hartlee Ⓜ Wilmington, N. C.; Jefferson Medical College of Philadelphia, 1902; died Dec. 23, aged 77.

Berry, Thomas M. Ⓜ Eldorado, Okla.; Kentucky School of Medicine, Louisville, 1898; served as health officer of Okmulgee County; at one time superintendent of the Western Oklahoma Hospital in Supply; died Dec. 19, aged 84.

Cummins, John Biglow Ⓜ Fort Worth, Texas; University of Nashville (Tenn.) Medical Department, 1897; member of the American Academy of General Practice; in 1950 honored as "Doctor of the Year" in Tarrant County; member of the honorary staff of the Harris Hospital; died Dec. 31, aged 100.

Edwards, Thomas Burton, Cedar Hill, Mo.; St. Louis College of Physicians and Surgeons, 1909; died in St. Joseph Hospital, Kirkwood, Dec. 7, aged 84.

Evans, Albert Lee, Bonne Terre, Mo.; Barnes Medical College, St. Louis, 1900; veteran of World War I; on the staff of the Bonne Terre Hospital; died Dec. 29, aged 87.

Feldman, Joel William, Polk, Pa.; Columbia University College of Physicians and Surgeons, New York City, 1908; staff physician at the Polk State School; died Jan. 20, aged 73.

Ferguson, Allan Harvey Ⓜ Chicago; the Hahnemann Medical College and Hospital, Chicago, 1913; veteran of World War I; associated with the Illinois Masonic Hospital, where he was past-president of the medical staff; died in the Veterans Administration Research Hospital Jan. 19, aged 74.

Freyermuth, Otto George Ⓜ San Francisco; the Hahnemann Medical College and Hospital, Chicago, 1903; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; associated with the Hahnemann and Polyclinic hospitals; psychiatrist for the Criminal Courts in the San Francisco area; died Jan. 19, aged 82.

Gailey, Watson Ⓜ Bloomington, Ill.; born in Ashland, Sept. 7, 1882; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; served on the faculty of the Illinois State Normal University; specialist certified by the American Board of Ophthalmology; past-president of the Central Illinois Society of Ophthalmology and Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; in 1955 vice-chairman, Section on Ophthalmology, American Medical Association; veteran of World War I; medical consultant in India and Guatemala; founder and chief ophthalmologist at the Gailey Eye Clinic; on the staff of the Mennonite Hospital, where he was chief ophthalmologist, and where he died Jan. 19, aged 76.

Lawler, Frank John, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1912; for many years associated with the Veterans Administration Hospital; died Dec. 4, aged 68.

Lawson, Edward Kirby Sr., Harrisburg, Pa.; Temple University School of Medicine, Philadelphia, 1911; fellow of the American College of Surgeons; past president of the Dauphin County Medical Society; formerly associated with the Harrisburg Polyclinic Hospital; served as physician and surgeon for Dauphin County Prison; died Jan. 8, aged 72.

Leader, George Howard Ⓢ Penn Yan, N. Y.; Kentucky University Medical Department, Louisville, 1906; veteran of World War I; on the staff of the Soldiers and Sailors Memorial Hospital; past-president of the Rotary Club; died Jan. 4, aged 76.

Lee, Norman Leon Ⓢ Philadelphia; Howard University College of Medicine, Washington, D. C., 1932; cited by the government for services to the U. S. Selective Service System; died Jan. 11, aged 55.

L'Esperance, Elise Strang Ⓢ Pelham Manor, N. Y.; Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1899; for many years associated with the Cornell University Medical College in New York City, where she joined the faculty in 1910; past-president of the American Medical Women's Association; fellow of the New York Academy of Medicine; member of the American Association of Pathologists and Bacteriologists, New York Pathology Society, Harvey Society, and the American Radium Society; she and her sister founded the Strang Cancer Prevention Clinic in memory of their mother; a founder and head of the Kate Depew Strang Cancer Prevention Clinic and for many years on the staff of the New York Infirmary for Women and Children; head of a similar clinic, on the staff, and on the board of managers of the Memorial Center for Cancer and Allied Diseases; served as pathologist at the New York Hospital and the Harlem Hospital in New York City; formerly an associate commander of the Women's Field Army of the American Society for the Control of Cancer; in 1942 was presented with the Clement Cleveland Medal, awarded annually by the New York City Cancer Committee "for outstanding contributions to cancer control work;" received a medal, the 1946 award of the American Women's Association; won the 1951 Lasker Award of the American Public Health Association; consulting editor of the *Journal of the American Medical Women's Association;* died Jan. 21, aged 83.

Litterer, Ammon Buist Ⓢ Coral Gables, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1923; clinical assistant professor of dermatology at the University of Miami School of Medicine; veteran of World War II; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; associated with St. Francis Hospital in Miami Beach and the Jackson Memorial and Victoria hospitals in Miami; died Jan. 1, aged 61.

Lord, Morris Sheldon, Schenectady, N. Y.; Syracuse University College of Medicine, 1890; veteran of the Spanish-American War; on the honorary staff of the Ellis Hospital, where he died Dec. 30, aged 91.

McConnaughy, James Barth Ⓢ New Kensington, Pa.; University of Pittsburgh School of Medicine, 1918; veteran of World War I; member of the Industrial Medical Association; medical director since 1922 of the New Kensington Works of Aluminum Company of America; on the staff of the Citizens General Hospital, where he died Jan. 7, aged 65.

McKowen, John Ⓢ Baton Rouge, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1912; veteran of World Wars I and II; fellow of the American College of Surgeons; affiliated with Our Lady of the Lake Hospital and Baton Rouge General Hospital, where he died Jan. 4, aged 69.

Martindale, Elihu Arthur Ⓢ Hillsdale, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; died in the Foote Memorial Hospital, Jackson, Jan. 1, aged 88.

Magee, Chester Lea, Carmel, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1899; veteran of World War I; consulting physician for the Southern Pacific Railroad; died Jan. 2, aged 88.

Maglio, Murrill Willis, Lepanto, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1925; veteran of World War I; died in the Veterans Administration Hospital in Kansas City, Mo., Jan. 21, aged 61.

Mason, Robert Macon Ⓢ Murray, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1912; affiliated with the Murray Hospital, formerly the Mason Memorial Hospital, of which he was co-founder; a charter member of the Rotary Club; died in the Murray Hospital Jan. 14, aged 70.

Maxwell, Paul Ⓢ Mount Union, Pa.; Medico-Chirurgical College of Philadelphia, 1916; past-president of the Huntingdon County Medical Society; on the courtesy staff of the J. C. Blair Memorial Hospital at Huntingdon; past-president of the Mount Union Rotary Club; died Jan. 1, aged 65.

Mays, William Clifford Ⓢ Stanaford, W. Va.; University of Louisville (Ky.) Medical Department, 1911; veteran of World War I; physician for the New River Coal Company; died Jan. 11, aged 72.

Mercurio, Pasquale James Ⓢ Brooklyn; Boston University School of Medicine, 1937; veteran of World War II; associated with the Norwegian Hospital and the Shore Road Hospital, where he died Jan. 10, aged 46.

Merrill, William Orville Ⓜ Detroit; University of Michigan Homeopathic Medical School, Ann Arbor, 1909; veteran of World War I; for many years chief of the eye, ear, nose and throat department at Highland Park (Mich.) General Hospital; died in the Harper Hospital Jan. 6, aged 73.

Miller, Irvin, New Rochelle, N. Y.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1939; certified by the National Board of Medical Examiners; specialist certified by the American Board of Obstetrics and Gynecology, fellow of the American College of Surgeons; served on the staffs of the New York Polyclinic Medical School and Hospital and the New York Post-Graduate Medical School, New York City; on the staffs of the Lincoln Hospital in New York City and the New Rochelle Hospital, where he died Jan. 26, aged 44.

Miller, Joseph Samuel, Scarsdale, N. Y.; University of Illinois College of Medicine, Chicago, 1933; interned at the Cook County Hospital in Chicago; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychoanalytic Association, American Psychosomatic Society, and the American Psychiatric Association; veteran of World War II; on the staffs of the White Plains (N. Y.) Hospital and the New York Psychoanalytic Institute; died Jan. 16, aged 49.

Moorer, William M. Ⓜ Lodge, S. C.; Medical College of South Carolina, Charleston, 1904; chairman of the school board; served as mayor; died in the Colleton County Hospital, Walterboro, Jan. 5, aged 78.

Morris, Roger Sylvester Jr. Ⓜ Ludington, Mich.; University of Chicago, The School of Medicine, 1940; interned at the Henry Ford Hospital in Detroit, where he served a residency; formerly a resident at the Presbyterian Hospital in Chicago and the University of Chicago Clinics; served as assistant professor of medicine at his alma mater; veteran of World War II; died Dec. 30, aged 47.

Muller, Robert Anthony, New York City; born in Carlsbad, Austria, May 18, 1895; Deutsche Universität Medizinische Fakultät, Prague, Czechoslovakia, 1921; specialist certified by the American Board of Physical Medicine and Rehabilitation; member of the American Rheumatism Association and the American Society of Physical Medicine and Rehabilitation; on the faculty of Columbia University College of Physicians and Surgeons; served as director of physical medicine at St. Barnabas, Columbus, and St. Giles hospitals, and the Presbyterian Home; associated with the Presbyterian Medical Center, Lenox Hill and Mount Sinai hospitals, and the Hospital for Joint Diseases; director of physical medicine at St. Luke's Hospital, where he died Jan. 12, aged 63.

Myers, Jacob Ⓜ Sherman Oaks, Calif.; Rush Medical College, Chicago, 1905; served on the faculty of his alma mater; fellow of the American College of Surgeons; formerly practiced in Chicago, where he was on the staff of the Woodlawn Hospital and connected with the Spalding School for Crippled Children; died Jan. 19, aged 75.

Noyes, Edmund Francis Ⓜ Dixon, Wyo.; University of Denver Medical Department, 1897; died in the Memorial Hospital, Craig, Colo., Dec. 31, aged 90.

O'Brien, Joseph Michael, Pittsburgh; Loyola University School of Medicine, Chicago, 1930; veteran of World War II; associated with the Pittsburgh Hospital; for many years county school physician; died Jan. 9, aged 58.

O'Connell, William Michael Ⓜ Nutley, N. J.; George Washington University School of Medicine, Washington, D. C., 1938; veteran of World War II; associated with the Hudson County General Hospital in Secaucus, Berthold S. Pollak Hospital for Chest Diseases in Jersey City, and St. Mary's Hospital in Hoboken; died in the New York Hospital in New York City Jan. 12, aged 46.

Osgood, Frederick Luke Ⓜ Saxtons River, Vt.; born in 1872; University of Vermont College of Medicine, Burlington, 1894; a member of the state board of mental health, on which he served for the past 35 years; served on the Rockingham Board of School Directors for many years; a justice of the peace of the town of Rockingham for 24 years; on Nov. 14, 1954, the state of Vermont dedicated the "Osgood Building" at the Vermont State Hospital in Waterbury in his honor; representative of Rockingham to the legislature from 1917 to 1923 and senator of Windham County from 1921 to 1929; an honorary member of the medical staff at Rockingham Memorial Hospital in Bellows Falls; since 1939 a director of the Bellows Falls Trust Company; died Jan. 10, aged 86.

Parks, Arthur Arnold, Crafton, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1901; president of the Crafton Board of Health; served on the staffs of the Southside and Allegheny General hospitals in Pittsburgh; died in Pittsburgh Jan. 3, aged 81.

Peterson, Norman Vern Ⓜ Rye, N. Y.; George Washington University School of Medicine, Washington, D. C., 1922; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society; emeritus director of the eye, ear, nose and throat department at the United Hospital in Port Chester; died in Avon Park, Fla., Jan. 15, aged 67.

Prichard, Horace De Witt Ⓜ Wichita Falls, Texas; University of Texas School of Medicine, Galveston, 1917; fellow of the American College of Surgeons; honorary member of the staff, Wichita General Hospital; veteran of World War I; died Jan. 9, aged 69.

Quinn, Raymond James Ⓜ Waterbury, Conn.; College of Physicians and Surgeons, Baltimore, 1913; veteran of World War I; served as city bacteriologist and welfare department physician; associated with St. Mary's Hospital, where he died Jan. 13, aged 66.

Riecker, Herman Harlan, Ann Arbor, Mich.; Johns Hopkins University School of Medicine, Baltimore, 1923; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Society of Clinical Investigation; veteran of World War I; past-president of the Washtenaw County Medical Society; for many years on the faculty of the University of Michigan Medical School; on the staff of St. Joseph Mercy Hospital, where he died Jan. 4, aged 63.

Robertson, Jarratt Padgett Ⓜ Birmingham, Ala.; Vanderbilt University College of Medicine, Nashville, Tenn., 1923; specialist certified by the American Board of Urology; member of the American Urological Association and past-president of the Southeastern section; associate professor of urology at the Medical College of Alabama; associated with South Highland Infirmary, Crippled Children's Clinic Hospital, University Hospital, and St. Vincent's Hospital; died in the South Highland Infirmary Jan. 17, aged 60.

Ross, Thomas Trigg Ⓜ Gurdon, Ark.; Tulane University School of Medicine, New Orleans, 1928; health officer of Clark County; specialist certified by the American Board of Preventive Medicine; for many years state health officer; died Jan. 1, aged 60.

Scales, John Perkins Ⓜ Livingston, Ala.; Louisville (Ky.) Medical College, 1897; past-president of the Sumter County Medical Society; veteran of the Spanish-American War and World War I; served as physician to Livingston State College from 1930 to 1946; formerly county health officer; for many years surgeon for the Southern Railway; died in the Veterans Administration Hospital, Tuscaloosa, Dec. 30, aged 87.

J.; Hahnemann Medical College and Hospital of Philadelphia, 1895; for many years practiced in Collingswood, where he was first health officer and organized the board of health; for many years attending physician at the Methodist Home for Aged in Collingswood; president of the first Collingswood Bank and member of the board of health; one of the founders and formerly on the staff of the West Jersey Hospital in Camden, where he died Dec. 20, aged 84.

Smith, Lester Alvin Ⓜ Indianapolis; Rush Medical College, Chicago, 1916; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society and Radiological Society of North America; fellow of the American College of Radiology; associate professor of radiology at the Indiana University School of Medicine; veteran of World War I; member of the staffs of Methodist, St. Vincent's, and Indianapolis General hospitals; died Dec. 15, aged 68.

Speicher, George Franklin Ⓜ Somerset, Pa.; Baltimore Medical College, 1910; for many years a member of the school board of Rockwood, where he was a director of the Union National Bank and the Coal Operators Casualty Company; associated with the Somerset Community Hospital and the Somerset State Hospital; died Dec. 25, aged 75.

Stoughton, Arthur Volney Ⓜ Claremont, Calif.; Ohio Medical University, Columbus, 1898; served on the faculty of the Pomona College, where he was college physician; first president of the Pomona College Alumni Association; died Dec. 26, aged 86.

Summers, William Boyd Ⓜ Casper, Wyo.; University of Colorado School of Medicine, Denver, 1951; interned at Mount Sinai Hospital in Miami Beach, Fla.; served a residency at the Veterans Administration Hospital in Denver; on the staff of the Memorial Hospital of Natrona County; died in Denver Dec. 1, aged 32.

Wells, William Albert Jr., Washington, D. C.; Howard University College of Medicine, Washington, 1907; also a graduate in law and pharmacy; served on the faculty of his alma mater; died in Washington Hospital Center Dec. 19, aged 85.

FOREIGN LETTERS

AUSTRIA

Cerebral Lipoidoses.—At the meeting of the Austrian Pediatrics Society in January, Dr. H. F. Seitelberger said that cholesterol thesaurismosis, phosphatide thesaurismosis, amaurotic idiocy, lipochondrodystrophy, and lipid histiocytosis are essentially endogenous cellular enzyme disturbances in the metabolic chains of the sphingolipoids: ganglioside, cerebroside, and sphingomyelin. The blockage of certain enzymatic reactions leads to pathological storage of certain substances within the cells. The storage or accumulation of a certain lipoid in each case is caused by the blockage of a distinct enzymatically regulated reaction within the metabolic chain of the sphingolipoids. In lipochondrodystrophy, the most frequent of this group of diseases, not only is ganglioside stored in the cells of organs, but also the mucopolysaccharide-lipoid complex. The disturbance responsible for this storage is to be found at a connecting point of the lipoid and polysaccharide metabolism. It is characteristic of lipid histiocytosis that cerebroside storage takes place exclusively in the reticulohistiocytic system, that is, in the brain it takes place only in the periadventitia of the vessels. The speaker stated that the anatomic differences between the infantile, late infantile, adolescent, and other forms of amaurotic idiocy are to be found in the degree of penetrance of the existing genetic enzyme disturbance. In the presence of a gene mutation of high penetrance, the disease will begin early and will be severe and short. The postinfantile forms with lesser penetrance are of longer duration, and the lesions in the brain are less severe, have local fluctuations in intensity, and show characteristics pointing to the manifestation of vital cellular reactions to the disease process.

In commenting on this report, Dr. H. H. Gross, of the Neurohistological Laboratory of the Mental Hospital of Vienna, stated that so far studies were made on 546 brains of patients in whom severe imbecility had been diagnosed as either congenital or acquired in early childhood. Contrary to expectation, the percentage of patients with cerebral lipoidoses was small. Only five cases of lipochondrodystrophy and three of amaurotic idiocy were found. He admitted, however, that whereas the clinical diagnosis of lipochondrodystrophy, thanks to its characteristic physical symptoms, causes no difficulties, the recognition of the various forms of amaurotic idiocy is still difficult, particularly if the patient has no history of a familial tendency.

BELGIUM

Lysosomes.—At a meeting of the Medical Academy Dr. De Duve of Louvain stated that lysosomes were first recognized in the liver. They are corpuscles with a diameter slightly smaller than half a micron, and contain an enzyme in a lipoprotein casing. They act only in an acid environment and only after the rupture of the protective casing. They have been detected in the kidney also, where they seem to be indistinguishable from particles recognized by Gerard and Cordier as having the power of phagocytosis. The role of the lysosomes is still unknown but it is believed that they may play a part in autodigestive and degenerative phenomena.

Hiatal Hernia.—At a meeting of the Belgian Society of Gastroenterology a symposium on hiatal hernia was presented. This condition was attributed to such factors as old age, obesity, abdominal hypertension, endocrine disturbances, and pregnancy. Le Cluyse of Brussels reported a series of 36 patients and concluded that the incidence of hiatal hernia could not be accurately determined because many patients are asymptomatic. The associated pain may be due to esophagitis, esophageal reflux, or incarceration of the hernia. Operation is indicated for acute hemorrhage of the upper gastrointestinal tract and constant or recurrent pain. Medical treatment is only palliative. The speaker stressed the diagnostic value of gastroscopy in these patients.

Deloyers and van der Stricht emphasized the necessity of evaluating the surgical treatment of hiatal hernias. Correction of the anatomic defect should relieve symptoms and restore normal functions. The speakers preferred a modification of Allison's technique. Deloyers emphasized the importance of team work by the internist, gastroenterologist, cardiologist, roentgenologist, and surgeon. Recurrences are seen in about 10% of those operated on. This is because of the friability of the tissues of this region.

CHILE

Penicillin and Rheumatic Heart Disease.—An investigation of the effect of penicillin on acute rheumatic fever and valvular heart disease was undertaken in the Jose Joaquin Aguirre and Roberto del Rio hospitals of Santiago, under the sponsorship of the Commission on Streptococcal Diseases, U. S. Armed Forces Epidemiological Board, the Western Reserve University School of Medicine, the University of Chile, and the Chilean National Health Service. The results of the first year of the study were reported by Mortimer and co-workers (*Revista médica de Chile*, vol. 87, 1959). In this series of 97 patients with acute rheumatic fever, 49 received large doses of penicillin for six weeks, and 48 controls received no antibiotic. The penicillin appeared to have no effect on the acute clinical, laboratory; and electrocardiographic manifestations of the disease but did reduce the incidence of valvular heart disease; 52% of the control group exhibited valvular disease one year after the acute attack as compared to only 21% of those who received penicillin. The disparity between the effects on the acute manifestations and those on endocardial lesions suggests two pathogenetically different processes. The observed effects of penicillin indicate that valvular heart disease may depend in part on a continuing stimulus from living streptococci, even after the symptoms of rheumatic fever have disappeared. It is concluded that an intensive course of penicillin is justified as a preventive of valvular heart disease.

Health Progress.—According to the Yearbook of Causes of Deaths of the Department of Vital Statistics, there has been a great progress in the lowering of the death rate in the 10 years, from 1948 to 1957. The crude death rate dropped from 16.9 to 13.7 deaths per 1,000. The infant mortality (deaths under one year of age) decreased from 145.9 to 117.7 deaths per 1,000 live births in the same period. This is still much too high. In the same period the crude birth rate increased from 35.9 to 38.4 births per 1,000 population. A new maternal health law provides payments for mothers from the sixth month of pregnancy on if they accept treatment by the Mother and Child Welfare Department of the National Health Service.

FRANCE

Irradiation and Marrow Transplantation for Leukemia.—Prof. J. Bernard and Dr. G. Mathé, with a team of doctors at the Hospital St. Louis in Paris, treated a 13-year-old girl with acute leukemia by a combination of irradiation and injections of bone marrow from human donors. Although the method had been used experimentally in mice, this was the first human patient to be so treated. The trial was made as a result of the information obtained from the treatment in Paris of six Yugoslav scientists who accidentally received lethal or near-lethal doses of radiation from an experimental atomic reactor. They were saved by human marrow transfusions. These would normally be rejected owing to the formation of antibodies in the host, but irradiation just before the transfusion prevents this process. The girl was irradiated by exposure to 300 r from a cobalt bomb. This served the double function of destroying the leukemia cells and inhibiting the formation of bone marrow antibodies. Four transfusions of bone marrow from healthy donors were then given. The blood count returned to normal within a month. When last seen the girl was continuing to improve.

INDIA

Vitamin Deficiency and Gestoses.—Pai and Pate (*Indian Journal of Medical Research*, vol. 46, September, 1958) studied the relationship between thiamine, riboflavin, and niacin deficiency and the occurrence of toxemia of pregnancy. The excretion of thiamine, riboflavin, and niacin in toxemic patients was studied in 24-hour urine specimens before and after delivery. A test dose of 5 mg. each of thiamine and riboflavin and 50 mg. of niacin was given orally and the excretion of the respective vitamins was estimated. The urine specimens were collected on the 1st, 2nd, 5th, 6th, 10th, and 11th days after delivery and the results compared with those in normal subjects and in normal pregnancy. A deficiency in thiamine was found in the toxemic patients. This decreased after the test dose. The recovery was manifested clinically by the disappearance of edema and albuminuria and a gradual reduction in blood pressure.

The thiamine return after the test dose in patients whose pregnancy was normal was much lower than that in the nonpregnant control group. The dietary intake was 0.7 mg. of thiamine, 0.6 mg. of riboflavin, and 6 mg. of niacin daily, while in those with normal pregnancy these values were 0.85, 0.8, and 7 mg. respectively. There was no correlation between the dietary intake and the urinary excretion of these vitamins in toxemia or normal pregnancy. The percentage return of thiamine after the test dose in toxemias of pregnancy studied on 1st-2nd, 5th-6th, and 10th-11th days was significantly lower than that in the nonpregnant group, thus showing a state of unsaturation with regard to thiamine. Low values for riboflavin were obtained only in the first-second-day period, showing that unsaturation here existed only during this period, while no state of unsaturation was revealed with regard to niacin.

Action of Hormones on Involuntary Muscles.—A. P. Sharma (*Indian Journal of Medical Research*, vol. 46, September, 1958) stated that epinephrine, acetyl choline, and histamine are widely liberated in the body and play a vital role in regulating tissue functions by virtue of their local actions. These actions have been studied mainly on cardiac and involuntary muscles where they produce motor or inhibitory effects which vary in different animals, in different systems, and in the same system at different sites. Dual effects (both stimulation and inhibition of the same tissue) have also been observed. The activity of involuntary muscles is also influenced by the concentration of sodium, potassium, and calcium ions in body fluids. The author therefore studied the mechanism of these local hormones and the role of electrolytes, if any, in this mechanism. Experiments were conducted on the involuntary muscles of the isolated small intestine of rabbits. Epinephrine had an inhibitory effect under aerobic conditions, which was changed to stimulation under anaerobic conditions by previous treatment with acetyl choline, atropine, and potassium chloride. Sodium or calcium chlorides did not affect its action. Acetyl choline produced a stimulation under both aerobic and anaerobic conditions which was changed to inhibition by previous treatment with epinephrine, sodium chloride, and calcium chloride. With potassium chloride, stimulation was produced under both aerobic and anaerobic conditions.

Atropine in all concentrations and under both aerobic and anaerobic conditions inhibited the small intestine after preliminary stimulation. Stimulation was, however, produced after previous treatment with calcium chloride, though the antagonizing action to acetyl choline was retained. The stimulating action of histamine was changed to inhibition by previous treatment with atropine, calcium chloride, or potassium chloride. Sodium and potassium caused stimulation of intestinal activity; after previous treatment with the other electrolyte, stimulation was replaced by inhibition. Acetyl choline changed the inhibitory action of sodium and potassium chloride into stimulation. Epinephrine enhanced the inhibitory action of both. Calcium chloride caused a depressant action which was reversed by previous treatment with atropine. Thus it was seen that the effects of these local hormones and electrolytes varied, depending on the previous state of the intestine, and changed with changes in the electrolyte concentration of the surrounding fluid and also previous treatment with some other hormone. Most of them could produce either stimulation or inhibition. The different actions of these hormones in different sites and different species may be due to the different environmental conditions present at the time. This may possibly explain the different actions of local hormones on the involuntary muscles in different regions.

Urinary Excretory Patterns, Glucose Tolerance, and Shock Therapy.—N. G. Srinivasan and co-workers (*Indian Journal of Medical Research*, vol. 46, September, 1958) studied the urinary excretion of amino acids and the glucose tolerance of catatonic schizophrenic patients before and after electroconvulsive therapy. Urine samples were collected prior to the shock treatments, on days subsequent to the 7th and 10th treatments, and on the 5th and 10th days after termination of shock treatment. A marked fall in the excretion of most of the amino acids after the seventh shock was seen. With subsequent shocks there was a slight tendency for these values to rise but they never came back to the original level. The low values were maintained for some time even after termination of the therapy. Particularly low levels were obtained for glutamic acid, glycine, threonine, and aspartic acid. The glucose tolerance and other biochemical studies were also made prior to the shock treatments, after the 1st, 4th, 7th, and 10th treatments, and on the 4th, 7th, and 10th days after termination of the shock treatment. The total proteins, albumin, and potassium levels showed a significant rise, returning gradually to normal after the last electroconvulsive shock. The two-hour glucose values after shock were higher than the preshock values. The inorganic phosphate levels showed a significant fall corresponding to the levels of glucose, showing their utilization in the metabolism of glucose. Both tended to return to fasting levels after termination of the shock therapy, particularly on the 10th day after this termination.

Vitamin B_{12} and Nitrogen Metabolism.—B. D. Punekar (*Current Medical Practice*, vol. 2, December, 1958) studied the effect of vitamin B_{12} on the digestibility coefficient and nitrogen retention in rats. Male weanling albino rats distributed into two groups according to their body weights were served a corn and soy bean diet adequate in all vitamins except vitamin B_{12}. One group received this vitamin by injection in a daily dose of 0.2 mcg. for four weeks. A higher growth response was noticed in the group receiving vitamin B_{12}, suggesting a specific function for this vitamin in anabolism. These rats gained in weight much more rapidly than those without the vitamin. The digestibility coefficient did not show any significant difference in the two groups but a marked difference was seen in the amount of nitrogen retained in the presence of vitamin B_{12}, a much higher retention of nitrogen being noticed with its administration.

Meeting of Public Health Association.—At the third annual meeting of the Indian Public Health Association in Calcutta in December, Dr. Das Gupta criticized the meager expenditure on health under the First Plan. The problem of nonavailability of trained personnel could be solved if language or customs were not considered insuperable barriers to employment and service. Although scientific investigation for better control of tuberculosis is being made, scant attention has been paid to rehabilitating patients cured of tuberculosis. The control of leprosy, cholera, and smallpox must be undertaken on a national scale. Referring to such virus diseases as poliomyelitis and encephalitis, he said that each State Directorate should have a trained epidemiologist. There should be a central laboratory in each state provided with a virology unit. A midday meal should be provided for children in schools. More attention should be given to mental disorders. Finally, a medical section must be attached to each factory for the care of the workers.

Rupture of the Uterus.—N. S. Devi (*Current Medical Practice*, vol. 2, December, 1958) observed 41 cases of uterine rupture in 17,882 deliveries. This high incidence was due to inadequate facilities for antenatal care, most of these accidents occurring in the patients' homes, the distance between the home and the hospital in some cases being 75 miles. Only one patient in the series had had antenatal attention. Most patients were under 30 years of age, the youngest being 16 and the oldest 35. There was only one primigravida in this series, the parity varying between two and nine. Of the multiparous women in this series six had an otherwise normal labor when the accident occurred. Dystocia accounted for 18 of the cases. The labor was not prolonged in all these cases, its duration varying from 2 to 48 hours. Preexisting scars in the uterus accounted for nine cases. Three were due to excessive penetration by chorionic elements. There were five cases of traumatic deliveries in which internal podalic version was performed; the labor was prolonged and there was excessive retraction of the uterus over the fetus. Six multiparas had a normal vertex presentation and the rupture was at the cervicovaginal junction. Previous labors had been uneventful. The site of rupture was the lower uterine segment in 19 patients, the upper uterine segment in 9, the broad ligament in 7, and there was colporrhexis in 6. There were 18 maternal deaths (44% mortality) and 38 fetal deaths (92.7% mortality). Eight died before treatment could be given, 1 was given conservative treatment because she was unfit for surgery, and 32 were given total or subtotal hysterectomy.

Hypothermia in Cardiovascular Surgery.—Padhi and Nanson (*Journal of the Indian Medical Association*, vol. 31, Dec. 1, 1958) performed cardiovascular operations on 10 patients under hypothermia; 7 of these had atrial septal defect with marked shunts, 8.3 to 13.1 liters per minute passing through the defect, mainly left to right; 1 had a pulmonic stenosis and was operated on under direct vision; and 2 had aortic insufficiency of rheumatic origin. Here hypothermia was used as an adjunct, and was thought to give an added margin of safety. These two patients were cooled to 32 C and the aorta was clamped for 12 and 7 minutes respectively. For the patients with auricular septal defects, the time of circulatory interruption varied from 2.5 to 10 minutes and for the patient with pulmonary stenosis, the circulation was interrupted for 2.5 minutes. The rectal temperature during circulatory interruption varied from 28 to 32 C (82.4 to 89.6 F). All patients recovered.

NEW ZEALAND

Fee-for-Service Scheme for Medical Care.—The supplement to the *British Medical Journal* of Feb. 14 contains an article by A. W. S. Thompson, director of the division of clinical services, Department of Health, New Zealand. He discussed the existing (since 1941) fee-for-service scheme, and proposed modifications which should do away with the existing scheme's disadvantages. In New Zealand the government pays a benefit of up to $1.05 for each service by a general practitioner, increased to $1.75 for night, Sunday, or holiday services. Specialist services qualify for the same benefit, but, whereas the general practitioner can claim an extra fee from the fund for prolonged attendance (over 30 minutes), the specialist cannot. The benefit is intended to help the patient to pay the physician's bill. The physician is free to charge what he likes, within reason, the standard charge in general practice, over and above the benefit, being 70 cents for an office visit and $1.05 for a house call. Some doctors still accept the benefit as full payment. The benefit has remained unchanged since 1941.

The fee-for-service scheme works in two ways. Under the refund system the doctor sends out bills in the ordinary way, and patients obtain refunds on the basis of their receipted accounts. This method involves practically no government intervention in ordinary practice. About 25% of doctors, most of them specialists, work on this system. The alternative is the schedule system. The doctor takes only his extra charges (if any) from the patient direct, and claims the benefit by submitting to the Health Department daily schedules listing all patients attended. Most doctors send in their schedules fortnightly or monthly. No patients' signatures are required, but 1% of claims are checked by postal inquiry. The advantages of fee-for-service on these lines over any type of capitation scheme are that there is no contract of service between the private practitioner and any member of the public (the physician is not "bound to his patient by the iron fetters of a legal contract enforceable day and night at the whim of the patient") and that there is free choice on both sides. The result is that complaints about failure to attend patients, or of rudeness or arrogance on either side over calls at inconvenient times, while not unknown in New Zealand, are much rarer than they appear to be in Great Britain, and have no legal significance.

The refund method is excellent but has two defects from the medical point of view. One is that no benefit is payable unless the patient first settles the doctor's bill, and in consequence all refund practitioners have a proportion of bad debts. Even if the doctor charges no more than the bare amount of the benefit, some patients fail to pay their bills. For this reason there has been a tendency in recent years for doctors to change from refund to schedule. A similar but more serious defect is that it would be a hardship for many patients to have to find the cash to pay their accounts in full, even though they could afterward obtain refunds for all or most of the amounts due. Some practices could hardly be run on a refund system, despite full employment and a high living standard. Both public and doctor would suffer if such a system were universal.

A simple modification of the fee-for-service scheme that would correct most of its faults is the patient schedule system. Doctors would be paid so much by the state for every patient seen in any calendar month, irrespective of the number of times the patient had been seen in that month. In all other respects the scheme would be worked exactly as the fee-for-service schedule system works now. There would be no interference with the refund system, which has no serious defects so long as it is not compulsory. A global sum is agreed on to represent 67% of the agreed aggregate gross income of all general practitioners. For the first few years of the new scheme 8.3% of this pool would represent the sum to be distributed monthly. Doctors would submit a certified return of patients seen, giving date of first attendance in that month only. After about five years it should be possible to arrive at an agreed amount to be paid per patient per month, and the pool system could then be abandoned.

UNITED KINGDOM

Goiters in School Children.—A survey of school children in North Oxfordshire showed a relatively high incidence of thyroid enlargement. The mean incidence of enlargement was 40%, compared with 6% in Oxford city. The normal limit for adolescents is about 3%. A survey made 15 years ago showed that an increase in thyroid enlargement of 27% has occurred since then. The district in question lies on a belt of limestone and marl (clay mixed with calcium carbonate) soil that is deficient in iodine. Water drawn from local wells contained from 0.6 to 3.9 mcg. of iodine per liter. Levels below 3 mcg. are considered to be goitrogenic. Owing to its high calcium content the water is hard, and such water is thought to interfere with the utilization of iodine. Most of the milk and farm produce in this goitrogenic area is grown locally, in iodine-deficient soil, whereas the food eaten in Oxford city is obtained from national markets.

Smoking in Schools.—A survey of the smoking habits of 8,314 children in Oxfordshire schools by a health officer revealed that 193 boys were aged 7 or less when they smoked their first cigarette. Of 4,270 boys interviewed, 2,853 or 67% had tried smoking, and 1,245 or nearly 30% had continued to do so. Of 4,044 girls interrogated, 1,276 or 31.5% had tried smoking, but only 328 or 8% had continued the habit. Family influence played a part in determining whether the children smoked or not. Less than 20% of those who smoked came from families where the parents did not smoke. When both parents smoked the chances that their children would smoke were three times as great as in nonsmoking households. The places where the children smoked were mainly in the home and at the cinema. One of the girls smoked 75 cigarettes a week.

Cutaneous Leishmaniasis.—At a meeting of the Royal Society of Tropical Medicine and Hygiene Prof. P. Garnham and Dr. D. Lewis referred to the rising incidence of cutaneous leishmaniasis in collectors of chicle in British Honduras. These workers enter the forests at the beginning of the rainy season, live a nomadic life moving from one camp to another, and go back to their families when the rainy season is over. Their lesions are found mainly on the ears. The ulcers are chronic and ultimately lead to destruction of the organ involved. An animal reservoir for the causative parasite appears probable, as the chicle gatherers are so sparsely distributed and stop such a short time in one spot that the usual vector, the Phlebotomus, would have little opportunity or time to acquire the infection from one person and pass it on to another. Fourteen species of Phlebotomus were found on local animals. The most satisfactory control measure would probably be an attenuated vaccine.

Emotional State and Energy Expenditure.—It has been generally supposed that euthyroid nervous subjects show a tendency toward a high basal metabolic rate and that diagnostic errors due to emotional upsets may easily be made. This view is challenged by Melville and Mezey (*Lancet* 1:273, 1959), who investigated the strength of the association between the emotional state and oxygen requirements in the lying, sitting, and standing positions in 32 psychiatric patients and 10 healthy subjects. The serum protein-bound iodine levels of all subjects were within the normal range. The psychological state, which varied from almost normal to severe delusional fear, was estimated on a four-point system referring to symptoms indicating emotional disturbance. Two independent ratings were made, one before testing and the other during the test procedure. It was expected that the more disturbed patients would show higher energy expenditures than the controls, but the results did not confirm this. The mean oxygen consumption of the mentally disturbed patients was not significantly different from that of normal subjects in the lying and sitting positions, and was actually less in the standing position. The most striking finding was the absence of any relationship between emotional state and rate of oxygen consumption.

Sterilizable Blankets.—Woolen blankets are a potent source of cross-infections in hospitals because they attract bacteria and disseminate them in lint. Attempts to sterilize blankets reduce their life to a matter of months. Calnan (*Lancet* 1:300, 1959) solved the problem of the hospital blanket after studying the method used by the Everest expedition for keeping warm. The mountaineers wore string vests under a wind-proof garment. The blanket substitute, which resembles a string vest in structure, consists of a warp-knit mesh fabric of viscose and cotton between two cotton sheets. The three layers are quilted together on a sewing machine. Cotton sheeting is attached to each side of the blanket substitute to allow for a tuck-in. Such blankets have been in use for over a year. After their introduction there was a noticeable reduction in the amount of dust and lint in the wards. The blankets, unlike woolen ones, can be sterilized by boiling or autoclaving without loss of texture.

Health and Social Class.—At a meeting of the British Sociological Association in January Dr. J. N. Morris said that preventable disease is more likely to occur in those of lower social class, because it takes longer for the less educated sections of the population to benefit from the newer knowledge on child rearing, advances in medical science, and medical services offered by the state. On the other hand, social class is not as rigid as it was formerly. There is now greater mobility up and down the social scale, which is largely based on income, status, and residence. It appears that the mentally and physically healthy move up and the unfit move down the social ladder. There has always been, and still is, a substantially higher death rate among the economically underprivileged. There is a closing of the social classes with respect to illness in children. Mortality and morbidity are decreasing more rapidly in children of the lower social classes. A study of the death rate from rheumatic heart disease or the incidence of chronic otitis media shows this.

Dr. Morris drew attention to the preponderance of schizophrenia among the unskilled young men of the lowest social class, which is a result of the mentally unbalanced dropping into a lower income group on account of their illness and lack of earning capacity. Poliomyelitis, on the other hand, is a relatively new disease affecting chiefly those of higher social classes. There is an inverse relationship of paralytic poliomyelitis to the level of sanitation and to infant mortality. Lung cancer and duodenal ulcer, which showed no relation to social class 20 years ago, now show a rising mortality with a fall in the social scale from higher to lower class. Coronary artery disease, which has an increased incidence in higher social classes, appears to be associated with limitation of physical activity. This is understandable, as a rise in social class is associated with a more sedentary job and diminished physical activity. Light workers 45 to 54 years of age show the same rates of ischemic myocardial fibrosis in all the social grades. A rise in the standard of living, with its decrease in physical work, is likely to increase the incidence of coronary artery disease.

Smog.—In the last week of January smog in Britain, particularly in the northwest, was stated to be the worst in living memory. The demand for hospital beds increased sharply owing to the smog aggravating chronic respiratory ailments, especially among the elderly. In Salford the smog appeared as a widespread smoky haze limiting visibility to 200 yd. or less. In this town the smoke averaged 120 mg. per 100 cu. m. and the sulfur dioxide 0.35 ppm. At one period the smoke figure rose to 478 mg. per cubic meter and the sulfur dioxide to 1.64 ppm, about eight times the January average. The demand for hospital beds was so great that hospitals rejected applicants unless their need was urgent. In 1956 the Clean Air Act was passed. Attempts are being made to implement this by creating smokeless zones and by discouraging the use of open coal fires in homes. In the last two years more than 125 local authorities in England and Wales decided to use their powers under the act to enact smoke-control orders. Unfortunately, the "black areas," where smog is most frequent and morbidity from respiratory disease is highest, are among the slowest to comply with the orders.

Influenza.—Influenza has reached a peak in London, whose inhabitants are also suffering from colds, bronchitis, and other respiratory diseases. These are undoubtedly associated with winter fogs and atmospheric pollution. There is a great demand for hospital beds and the services of general practitioners. The London Local Medical Committee, which represents 2,000 doctors in the London area, sent out a request to 3,250,000 patients to defer calling in the physician unless it is absolutely necessary. Patients have also been asked to make their telephone calls early in the day so that the physician can arrange his visits accordingly. In many districts physicians are finding it difficult to cope with the additional sickness. Patients are asked to defer visits for a week or two if their condition does not need immediate treatment. Hospitals have been told to restrict admissions to emergency cases only. The influenza epidemic is mild. Very few deaths have been reported. Although some of the attacks are attributed to the Asian virus, most of them are probably due to virus B. School children are suffering most. Many schools are only half-filled because of influenza, measles, chickenpox, and bad colds. In one area scholarship examinations of 11-year-old children have been deferred because of absence. In Blackpool there is much absenteeism due to "four day influenza." At Ripley Hospital in Derbyshire no more operations are being performed for the time being because of influenza among the patients and staff.

Militarized Medicine.—Sir George Schuster, chairman of the Oxford Regional Hospital Board, in a survey made for the Acton Society Trust suggested that the Ministry of Health be reorganized and remodeled along army lines (Creative Leadership in a State Service, London, 1959). He considered that the hospitals should be regarded as part of a fighting service and that heads of hospital boards should look to the Ministry of Health for leadership and direction in the same way that army commanders do to their commander-in-chief. Medicine would then have two top posts corresponding to the chief of the imperial general staff and to a combination of the posts of adjutant general and quartermaster general. These positions would be occupied by persons with hospital experience at an operational level. A new type of skilled administrator is needed in the health service, according to Sir George. At present there are not enough top management posts in the hospital service and the pay for those that do exist is inadequate.

Sir George criticizes the present scheme of hospital management. At present this is largely autonomous and in the hands of boards and committees whose members are mainly unpaid volunteers from the hospital staff. They are entrusted with the spending of large sums of money. While he admits the value of such voluntary effort, he believes that economy and efficiency would be improved by intensive, expert study of hospital costs and by the use of work-study programs and other efficiency techniques. While it would be inadvisable to replace this volunteer system entirely by paid officials, it is thought that efficiency would be improved by the introduction of professional administrators, and the formation of central intelligence and statistical departments.

Unlawful Attendance at Wife's Confinement.—A man pleaded guilty to attending his wife's confinement without medical supervision and not in an emergency. This is an offense under the Midwives Act, which requires that only a midwife or doctor may attend a confinement except in emergencies when they are not available. A woman consulted her physician early in her pregnancy and informed him that she would like her husband present when the baby was born. As the physician disapproved she decided to do without him. The pregnancy and puerperium were normal and uneventful. The prosecution was brought by the local county council, which sent a health visitor to see the baby after the husband had sought advice about obtaining a maternity allowance under the National Health Service. The judges gave her husband, who pleaded that he did not know that he was committing an offense, a conditional discharge.

Reduction of Carcinogens in Tobacco.—Dr. E. Wynder (*British Medical Journal,* Feb. 7, 1959) stated that man will continue to smoke, whatever evidence is presented regarding an association between tobacco and cancer. The most practical solution is to render tobacco smoke noncarcinogenic, or at least to reduce its carcinogenicity. This can be done by lowering the tar content of tobacco, reducing the temperature of combustion, and modifying its pyrolysis. It is unlikely that the tar content of tobacco can be reduced by any great extent by effective selection, as the various kinds of tobacco have much the same carcinogenic activity; but an effective filter would help. This practical step should be undertaken by the tobacco industry without delay. A marked reduction in the carcinogenicity of some of the major cigarette brands has already taken place. While such a move will not prevent smokers' developing lung cancer present evidence indicates that it will reduce the chances.

Wynder and his group are currently engaged in a study of the action of a number of substances, including aluminum compounds, to determine whether the temperature of tobacco during smoking can be lowered sufficiently to influence the formation of polynuclear substances. Several suggestions have been made for cooling the main stream of the smoke. The formation of carcinogens is related to the burning temperature rather than to the presence or absence of oxygen. Thus the activity of an 880 C tobacco pyrolysate in nitrogen is similar to that obtained with access of oxygen, but if the temperature is reduced below 700 C the carcinogenicity is reduced. Wynder is investigating the effect of catalysts on the reduction of the polynuclear content of tobacco smoke condensate. These studies are in the preliminary stage and it remains to be determined through combined biological and chemical investigations whether there is a particular catalyst or group of catalysts which could reduce the carcinogenicity of tobacco smoke and still be practical.

Hospital Leadership.—The main conclusion of a survey of hospital organization and administration in the past 10 years, made by the Acton Society Trust, entitled "Creative Leadership in a State Service—a General Survey," is that the Ministry of Health, while handling its administrative tasks fairly and sensibly, does not yet offer inspiring leadership to the decentralized authorities. Considering how such leadership might be provided Sir George Schuster, chairman of the trustees and himself chairman of a regional hospital board, discussed staffing of the Ministry, liaison between Ministry and regional boards, and provision of a central intelligence organization.

The creation of the National Hospital Service has resulted in the need for a new type of skilled medical administrator. Sir George believes that the Hospital Service could learn from both military organization and industry. The heads of hospital boards, for instance, should be able to expect from the Ministry of Health the leadership and direction which Army commanders would get from their commander-in-chief. From his own experience, Sir George repudiates the suggestion that the voluntary boards and committees, which are a unique feature of the British Hospital Service, are less concerned to insure the wise handling of funds than paid professional administrators would be. He would like to see economies effected not through progressive squeezing by the Ministry, but rather through expert study of the hospital cost structure, the use of efficiency techniques and industrial consultants, and the introduction of work-study methods. The survey is the subject of an editorial in the *British Medical Journal* of Feb. 14.

Children in Hospital.—Children should not be admitted to hospital if it can be avoided, according to an expert committee which made a two-year study of the arrangements for children in hospital. The committee, under Sir Harry Platt, found that at any given time in England and Wales there were nearly 40,000 children in hospital. Medical advance, said the committee, is making it possible to treat more children at home and so avoid the emotional disturbance caused by removing them from familiar environments. Greater attention should be paid to the emotional and mental needs of the child in hospital. The authority and responsibility of parents and the importance of mitigating the effects of the break with home should be more fully recognized. There is much to be said for admitting mothers with their children, especially if the child is under 5 years of age. Parents should be allowed to visit whenever they can and to help with the care of children.

The child should be allowed to take his favorite toys with him. Neither parent nor hospital should prevent his bringing something he loves on the grounds that it is not clean or respectable enough. The committee recognized the difficulty parents have in getting authoritative information about their children's progress. There should be fixed times at which parents could get such information first hand. Children and adolescents should not be treated in adult wards. There should be a plentiful supply of toys and games. All children's wards need a playroom, preferably one visible to those in bed. Hobbies, such as gardening, painting, and handicrafts, should be encouraged. The child, particularly at first, should be handled by as few people as possible. He should be able to get to know his own nurse. The *British Medical Journal* for Feb. 14 commented favorably on the report.

Carcinogens from Bonfires.—The garden bonfire is a major source of the carcinogen benzpyrene, according to Prof. F. C. Pybus of Durham University. Smoke from one of these smoldering heaps examined recently contained 70 parts of benzpyrene per 1 million of free carbon. The concentration of benzpyrene in tobacco smoke is 0.2 ppm. In coal smoke it is 300 ppm. The 180 million tons of coal burnt in a year produced 2,500,000 tons of smoke, against 18,000 tons from the 111,607 tons of tobacco burnt, but the coal yielded 750 tons of benzpyrene, compared with 8 lb. from the tobacco smoked. The author concluded that 90% of cancer is caused by the benzpyrene and other carcinogens in Britain's atmosphere. Great Britain has the smokiest air on earth.

The Insane Criminal.—Treatment with new drugs has transformed some patients who have been dangerously insane for years. Selected patients, many of them murderers, have for several months been given chlorpromazine, perphenazine, or prochlorperazine. Of 180 women patients so treated 30 were formerly so violent that they were locked in their cells permanently except for spells of exercise alone. Today only two are in isolation. The others are well enough to mix with other patients, work, and even attend dances in the concert hall. In one of the cell blocks for the most dangerous male patients is a man who murdered a prostitute 16 years ago. Before drug therapy he was incoherent and made only animal-like noises and was so dangerous that he could not be left alone with anyone except experienced male nurses. Four men had to hold him down for his first series of injections. Within seven days he was asking for the drug in tablet form. In two weeks he was holding normal conversations and working with other patients.

Another murderer had been in isolation for 10 years. In 1956 he was allowed out of his cell as an experiment, and his first response was to kick a nurse in the face. Now, after treatment, he is well behaved. This does not mean that cured patients will be released wholesale. These patients may have to take these drugs for the rest of their lives to remain normal. At this stage they could not be trusted to continue the treatment voluntarily if they were released, but these results are a great relief to the overworked staff. Not only do these people behave rationally but they are ambitious to get well and for the first time they are cooperating in their treatment.

CORRESPONDENCE

THE BASIC MEDICAL SCIENCES AND THE RESIDENCY PROGRAM

At the recent 55th Annual Congress on Medical Education and Licensure the residency program was the subject of a panel discussion, led by Dr. Wright Adams. One of the few points on which there was unanimous agreement was the difficulty in providing instruction at the graduate level in the basic sciences as they apply to the practice of the individual specialties. The important contributions of the basic medical sciences to advances in medicine through research have long been recognized. It is now becoming increasingly apparent that daily practice in the various specialties requires the application of specific physiological and other basic principles. This is recognized by the American specialty boards in their individual brochures, where the inclusion of instruction in the basic sciences as a part of residency training is stressed. The practical difficulty lies in finding available time and personnel to conduct this part of the total training program.

There is no question that the integration of basic and clinical instruction during daily ward rounds and seminars is one of the most effective ways of presenting both types of information. When the resident can relate certain principles of electrolyte balance to the treatment of an individual patient, the principles remain fixed and their application is readily recalled in future similar situations. Yet this alone is now insufficient. In the undergraduate medical curriculum, approximately one-half the total instructional time is devoted to the basic sciences as they relate to all branches of medicine. After completion of an internship, the future specialist usually spends the remainder of his formal training period in a residency program in which attention is focused on the area where he will practice throughout his career. Nowhere in this total program is there an opportunity for the systematic presentation of the important facets of the huge, steadily growing literature in the basic sciences as they apply to his field of specialization. Only in the university hospitals, which include a relatively small proportion of the total approved residencies, is it generally possible to obtain more than occasional visits from an anatomist, biochemist, microbiologist, pharmacologist, or physiologist. In such institutions, the faculty members usually carry such heavy undergraduate teaching schedules and research programs that they have little time left for regular courses for the hospital residents. Further difficulty lies in attempting to find class hours which the residents themselves can attend, uninterruptedly, with reasonable regularity. These problems are compounded in the nonuniversity community hospital, where the pathologist is generally the only basic science specialist on the staff. Even if funds were available to add others, the shortage of trained physiologists and biochemists would limit the use of this solution to the problem.

Recognition of this situation led the Graduate School of Medicine of the University of Pennsylvania to modify its curriculum this year. In the past, the school has offered courses in 14 medical specialties, in which correlated teaching in the basic sciences and their clinical application was conducted throughout the full academic year. This year, each course has been divided into a four-month basic semester and a four-month clinical semester. During the basic semester (September to January), students in all the specialties take the 192-hour correlated basic sciences course, in which is presented a review by body systems of the current literature in the basic sciences. The remainder of the basic semester of each course is devoted chiefly to instruction in the basic sciences as they apply to the individual specialty, and to seminars, conferences, and assigned reading in which the application of the basic sciences to clinical problems is stressed. The basic semesters in the various specialties were designed particularly for incorporation into the residency programs of approved hospitals.

During the current year, the first since the inception of the new program, approximately 50 physicians were sent to the school by their hospitals for the basic semester, in addition to the 200 enrolled for the full academic year. Opinions vary as to whether incorporation of the basic semester is most valuable during the early or latter part of the residency period. In general, we have found that the majority of physicians prefer taking the course after completion of approximately one year of residency. At that time, they have acquired sufficient clinical experience to serve as a background to the instruction offered and they have developed a strong appreciation of the need for further knowledge of the basic sciences in their areas of specialization. On returning to their hospitals after completion of the semester, they should be qualified to add materially to the local teaching programs.

The second, or clinical, semester (January to May) in each specialty is devoted primarily to clinical application and practice. The content of each full academic year's course at the school is thus essentially the same as in former years. This is of particular advantage to physicians who wish to enter the specialties after several years of general practice, to medical officers of the armed forces, who qualify for assignment to full year's courses, or who have just completed a tour of active duty, and to qualified physicians from abroad who desire a full year's training in the United States. Courses in the dental specialties and in veterinary medical sciences are given only as programs of a full academic year or longer.

Since its founding 40 years ago, the graduate school of medicine has striven constantly to develop more effective means of improving training in the specialties through application of the basic sciences. The present two-semester plan provides a means by which all approved hospitals can participate actively in its program.

THE NEPHROTIC SYNDROME

To the Editor.—The editorial on the nephrotic syndrome in The Journal (169:846 [Feb. 21] 1959) disturbs us since we are sure it will confuse many readers. It quotes two references by ourselves and our co-workers which deal with the nephrotic syndrome. The other reference is a paper by Hodges (*J. M. Soc. New Jersey* 54:11 [Jan.] 1957) which deals with the lower nephron syndrome—so-called lower nephron nephrosis or acute tubular necrosis. Since there is no clinical and pathological similarity between these two conditions, and treatment is completely different, the editorial is confusing and misleading. In discussing the nephrotic syndrome, the editorial states that "pathologically the characteristic lesion is necrosis of the tubules." This lesion is seen in lower nephron nephrosis but not in the nephrotic syndrome. There are no characteristic histological lesions in the kidneys of patients with nephrotic syndrome. This condition has many causes and many renal histopathological changes but certainly not tubular necrosis. Other points discussed in the editorial confuse lower nephron syndrome with the nephrotic syndrome. For example, we have never heard of the artificial kidney being used in the treatment of patients with the nephrotic syndrome, but this form of treatment is valuable in the management of patients with acute renal failure due to the lower nephron syndrome.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Charitable Hospitals: Immunity from Tort Liability.—This was an action for damages sustained by a patient as a result of the alleged negligence of the defendant hospital. From an adverse judgment, the plaintiff appealed to the Supreme Court of New Jersey.

The plaintiff alleged that he entered the defendant hospital for the purpose of having an operation performed on his eyes. After the surgery he remained at the hospital as a postoperative patient and wore protective bandages over his eyes. During this postoperative period, and through the negligence of the defendant's employees in failing to provide suitable guard-railings on his bed, he was permitted to fall out of bed with great force and with resulting serious injuries. The defendant moved to dismiss the plaintiff's complaint, asserting that since it is a nonprofit eleemosynary corporation it possesses an absolute immunity from any responsibility to the plaintiff for injuries resulting from its alleged negligent conduct. The motion was granted and summary judgment entered in favor of the defendant.

The immunity on which the defendant relies, said the Supreme Court, was first declared in our courts in 1925 as a judicial expression of the state's public policy; however, the reasonable demands and expectations of innocent persons injured through the fault of others has caused many of our judges to suggest pointedly that sound concepts of right, justice, and morality require outright rejection of the immunity. In the case before us, the single issue presented by the parties is whether or not the last vestiges of the judicially declared immunity should at this time be erased.

The common-law duty of due care, with tort liability for its breach, prevails generally through the law although it occasionally comes into conflict with immunities which must find independent support for continued recognition in their own historical and social justification. Professorial and student writings overwhelmingly oppose the immunity of charitable hospitals. Although these writings are free from the restraints of judicial responsibilities, they are worthy of careful consideration for they embody thoughtful and high-minded endeavors to stimulate the movement of our law toward the ever-present goal of obtaining a higher measure of justice for all people.

Professor Scott has extensively discussed three possible grounds which have been suggested for the exemption of charitable institutions from tort liability. The first is that where trust funds are devoted to charitable objects they should not be diverted from those objects and that payment of tort claims would amount to such diversion, but this legalistic view would deny liability in all tort cases. The second rests on an alleged waiver by the injured party, but such a waiver would be wholly fictitious and a figment of the imagination. The third rests on the inapplicability of the doctrine of *respondeat superior*, but the adoption of this approach would deny liability in all tort cases and would seem to disregard the true ground for vicarious liability in our law. The New Jersey decisions did not really subscribe to any of the foregoing bases but spoke almost exclusively in terms of the public policy as the judges then saw it. Thus one Supreme Court decision recognized that the diversion of the charity's trust funds, if any, was the same whether the tort claimant was a beneficiary or stranger; and another, after finding the plaintiff to be a beneficiary, declared immunity as the state's declaration of public policy.

Times and circumstances have changed, however, the court continued, and we do not believe that some of these early decisions represent current notions of rightness and fairness. Due care is to be expected of all, and when an organization's negligent conduct injures another there should, in all justice and equity, be a basis for recovery without regard to whether the defendant is a private charity. We are satisfied that the views recently expressed in the concurring and dissenting opinions in two New Jersey cases are much closer to the mores and ethical ideals of our times than the earlier cases decided several decades ago. In one of these the court noted that experiences in other jurisdictions had demonstrated that no calamitous social effects would result from dissolution of the charitable immunity; that the availability of insurance had obviated any threat that recoveries against charities would seriously deplete their funds and deprive communities of their benefits; and that individuals "should not be forced to suffer the unmitigated and oftentimes crushing burden of injuries wrongfully inflicted merely to continue a judicially inspired immunity long since outdated by the impact of modern times." The other decision pointed to the harshness and injustice of the immunity rule and questioned any present need for it in view of the widespread availability of insurance. It may be noted that charitable institutions in New Jersey have long been under some tort responsibilities for negligent injuries to others and presumably have protected themselves by adequate insurance coverage; if the enlargement of their tort responsibilities actually results in additional premiums, that should be considered as merely incidental to the rendering of equal justice to all innocent parties who are injured through the negligence of others.

The contention has been advanced that, even though the former public policy notions have been strongly altered, the elimination of the immunity should be left exclusively to the legislature. Judges of an earlier generation declared the immunity simply because they believed it to be a sound instrument of judicial policy which would further the moral, social, and economic welfare of the people of the state. When judges of a later generation firmly reach a contrary conclusion they must be ready to discharge their own judicial responsibilities in conformity with modern concepts and needs. It should be borne in mind, the court pointed out, that we are not dealing with a field of the law in which stability and predictability may be of the utmost concern. We are dealing with the law of torts, in which there can be little, if any, justifiable reliance and where the rule of *stare decisis* is admittedly limited. We find no merit in the defendant's contention that "this court may not constitutionally overturn the immunity doctrine." It seems to us beyond question that, in the absence of any definitive legislative public policy, this court has full power to overrule the earlier declaration of court of error and appeals either because it was originally erroneous or because it has become unsound in the light of modern conditions. Since earliest days our courts have recognized and discharged the vital responsibility of reexamining questioned decisions whether they be their own or those of their predecessors.

The primary function of the law is justice, and when a principle of the law no longer serves justice it should be discarded. In this case the law was embodied not in any controlling statute but in a judicial principle of the law of torts; it had no sound English common-law antecedents and found its way into American law through a misconception; it runs counter to widespread principles which fairly impose liability on those who wrongfully and negligently injure others; it operates harshly and disregards modern concepts of justice and fair dealing; it has been roundly and soundly condemned here and elsewhere; and the time has come for its elimination by the very branch of government which brought it into our system.

Since the dismissal of the plaintiff's complaint was grounded entirely on the defendant's alleged immunity which we now repudiate, concluded the Supreme Court, the judgement in favor of the defendant is reversed and a new trial ordered. *Collopy v. Newark Eye and Ear Infirmary,* 141 A(2) 276 (N. J., 1958).

Malpractice: Res Ipsa Loquitur; Failure to Pretest for Possible Drug Reaction.—This was an action for damages for injuries caused by the alleged negligence of the defendant physician. From a judgment in favor of the defendant, the plaintiff appealed to the district court of appeals, first district, division 1, California.

The plaintiff was referred by her regular physician to the defendant for a pyelogram, an x-ray study of the urinary tract. It is accomplished by the injection of an opaque iodine dye so that the inside of kidneys, ureters, and bladder can be photographed. The plaintiff testified that the defendant did not make any reaction tests and did not ask her whether she usually had reactions to injections or was sensitive to any particular substance. The defendant insisted that she did ask the necessary questions and that she did make an intradermal sensitivity test. On attempting to make the injection in the right arm, then the left arm, and finally in the veins of one of the wrists and hands, it was found that the plaintiff's veins were friable and had started to bleed. (During these unsuccessful attempts the defendant used about 10 cc. of the dye. Not all of it got into the plaintiff's veins but the defendant observed no adverse reactions to the amount that did.) Defendant therefore told the patient that the injection could be made in either the shoulders or the buttocks and the plaintiff chose the buttocks. After administering Novocain to deaden the pain the defendant proceeded to inject about 30 cc. of Neo-iopax. She admitted that Neo-iopax is an irritant, but she did not warn the patient that there might be a reaction because she did not expect one, never having observed one before. It appeared from the evidence that the manufacturer's comments about Neo-iopax indicated that it was to be used "for intravenous and retrograde urography" but made no mention of intramuscular injections. The defendant stated, however, that it was common practice in the community to inject it intramuscularly if it could not be injected intravenously.

Immediately after injection of the dye, the plaintiff experienced severe pain. An ulcer developed at the site of the injection which subsequently required surgery before it cleared up.

The plaintiff's main contention was that the doctrine of *res ipsa loquitur* applied. It is very doubtful, said the court of appeals, that the doctrine is applicable to the facts of this case. Whether the doctrine is applicable depends upon whether a layman can say, as a matter of common knowledge or observation, or from the evidence could draw a reasonable inference, that the consequences of the injection here involved were not such as ordinarily would have followed if due care had been exercised. In this case the injury arose at the site of the injection. The testimony of the various doctors was all to the effect that it is good and standard practice in this community to give such an injection subcutaneously if it cannot be given in the veins. The defendant testified as to why it was not possible or feasible to give this injection to the plaintiff intravenously. Thus, there is no basis at all for the plaintiff's assertion that there was an inference of negligence because the injection was here given subcutaneously. All the testimony is to the effect that the reaction here involved is one of the risks of such an injection. Such toxic effects are caused by the sensitivity of the individual patient to the dye solution. There would seem to be no basis for the doctrine of *res ipsa loquitur.*

We think, however, continued the court of appeals, that there was substantial evidence, independent of the doctrine of *res ipsa loquitur,* to support a verdict for the plaintiff. The defendant testified that she asked the plaintiff about her reactions to injections and made tests for sensitivity. Although she was skeptical about the value of such tests, the fact remains that the defendant claimed that she made such tests and asked the relevant questions. It is certainly a possible and reasonable inference from the defendant's testimony that the giving of such tests and the asking of such questions were common and standard procedure in this area. But the plaintiff testified that no such tests were given and no such questions asked. Thus, there is a direct conflict in the evidence on the vital issue of negligence. It is a reasonable inference from the evidence, and the jury could have found, that ordinary care required the giving of such tests and the asking of such questions. The jury could then find that it is negligence to fail to give such tests or to fail to ask such questions. Finally, the jury could have found that no such tests were given and no such questions asked by the defendant. Thus, there was a factual issue that should have been submitted to the jury.

The judgment of the trial court in favor of the defendant physician was accordingly reversed. *Horace v. Weyrauch,* 324 P(2) 666 (Calif., 1958).

Malpractice: Careless Remarks by Operating Surgeon.—This was an action for damages for injuries caused by the alleged negligence of the defendant surgeon. From a judgment of nonsuit, the plaintiffs appealed to the district court of appeals, third district, California.

The patient entered the St. Helena Sanitarium and Hospital for the purpose of having a rectosigmoid polyp removed from the lower portion of the large intestine adjacent to and immediately above the rectum by the defendant surgeon. After such an operation it is customary to examine the site of the polyp in order to ascertain whether or not the entire polyp has been removed. There was an attempt to make this examination just before the plaintiff left the hospital, but because of the pain caused to the plaintiff it was decided that the examination would be made at a later date and with the plaintiff under an anesthetic. Subsequently, therefore, the plaintiff returned to the hospital. She was given a general anesthetic, and a sigmoidoscope was inserted up her rectum without difficulty to the 15-cm. level. At this point the obdurator was removed because the defendant desired to pass the scope under direct vision. In attempting to advance the sigmoidoscope under direct vision slight difficulty was encountered, and on visual examination it was noted through the scope that a loop of the small intestine was visible. A diagnosis of accidental perforation of the sigmoid wall was made, and the plaintiff was immediately taken to the operating room where abdominal repair was performed.

The plaintiff husband testified that when the defendant came out of the operating room he approached him and said, "Boy, I sure made a mess out of things today, didn't I, Warren?" Asked what happened, he replied, "Well, by inserting my scope in your wife's rectum, I busted the intestine."

The defendant testified that a tear of the intestine is not an expected or anticipated thing and that he was totally unaware that the intestine had been torn until "it was noted that loop of the small bowel was visible."

The plaintiffs first contended that a judgment of nonsuit was not proper because of the application of the doctrine of *res ipsa loquitur*. The court held that the doctrine would not apply in the instant case unless it was shown that the accident was one that does not ordinarily occur in the absence of negligence. We cannot say, the court continued, that it is a matter of common experience that a rent in the intestine does not occur during a sigmoidoscopy in the absence of negligence. Expert testimony would be required. The only evidence introduced in this regard was a statement of the defendant that a tear is not anticipated or expected. The mere fact that the result is unexpected or not anticipated is not sufficient to invoke the doctrine of *res ipsa loquitur*.

The plaintiffs also contended that the extrajudicial admission of the defendant was sufficient to establish a prima facie case. The court said that on the issue of nonsuit the plaintiff was entitled to all favorable inferences that could reasonably be drawn from the evidence. What inferences were to be drawn from the defendant's statements, in the light of the facts and circumstances shown by the evidence, was a question of fact to be determined by the jury. We believe that the court erred in determining as a matter of law that no inference of negligence could be drawn from the evidence. We think that the jury could infer from the statement that in inserting the sigmoidoscope he did not use the degree of care ordinarily exercised by other doctors of good standing in the community, and, as a result of the lack of care, the patient's intestine was torn.

Accordingly the judgment of nonsuit in favor of the defendant surgeon was reversed. *Wickoff v. James,* 324 P(2) 661 (Calif. 1958).

Malpractice: Abandonment of Patient.—This was an action for damages resulting from the alleged abandonment of the plaintiff by the defendant physician after having accepted him as a patient. From a judgment in favor of the defendant, the plaintiff appealed to the court of appeals of Georgia.

After a traffic accident the plaintiff was taken to a hospital in Carrolltown, Ga., and from there to the Georgia Baptist Hospital, Atlanta, where the defendant was shown by the hospital charts to be the admitting physician. The plaintiff suffered a fractured left mandible, a fractured zygomatic bone, at least two fractured ribs, fractures of the vertebral column, and a fractured skull. After five days the plaintiff was removed to his home where the defendant saw him weekly for about four weeks, until he advised the plaintiff that he would have nothing further to do with the case. The plaintiff then consulted an attorney to force the defendant to furnish him proper treatment. At the time of the trial the plaintiff still suffered from some of the injuries, and he contended that he had been unable to procure medical treatment since the defendant "abandoned" him.

The plaintiff testified that the defendant told him on March 21 that he would not get well until he obtained surgical treatment but that he, the defendant, would not take care of him. The plaintiff also testified that another physician treated him several times up to March 18, when he said he was going to place him in a hospital.

There was no evidence, said the court, that the defendant abandoned the plaintiff at a critical time when there was a need for immediate treatment, for, although the record does disclose that the plaintiff needed surgical treatment, it does not disclose that such surgical treatment was needed then and there or that if the plaintiff had sought, within a reasonable time thereafter, other medical care he would have suffered any injury from the alleged abandonment. It is undisputed that the day after the alleged abandonment the plaintiff traveled from his home to Atlanta where, at the request of his attorney, he was examined by a physician who recommended that he see a plastic surgeon. It appears that any injury which the plaintiff suffered resulted from his own failure to obtain the treatment recommended for him.

The judgment for the defendant physician was therefore affirmed. *Carroll v. Griffin,* 101 S. E. (2) 764 (Ga., 1958).

MEDICAL FILM REVIEWS

No Man Walks Alone: 16 mm., black and white, sound, showing time 27 minutes. Presented as a public service by the National Paraplegia Foundation Inc., New York. Produced in 1958 by and procurable on rental ($12.50) or purchase ($150.00) from Film Features Inc., 1600 Broadway, New York 19.

This film deals with new developments in the physical rehabilitation of a paraplegic patient. It shows the experiences of a patient from the time he begins treatment for a broken back through his training and adjustment and finally his preparations for work. The teamwork of the hospital staff of physicians and therapists who help the paraplegic patient back to useful living is also shown. It is suitable for showing to lay groups and could also be used for fund raising purposes

Positioning the Patient for Surgery: 16 mm. color, sound showing time 27 minutes. Presented by the American Nurses Association and National League for Nursing Film Service in cooperation with the American College of Surgeons. Produced in 1958 by and procurable on loan from American Cyanamid Company, Surgical Products Division, 1 Casper St., Danbury, Conn.

This film demonstrates how the operating room nurse fulfills her responsibility for proper positioning of the patient on the operating table and performs those activities which help to maintain physiological functioning, conserve time and energy, prevent bodily injury, and provide for the comfort and dignity of the patient. The positions shown are dorsal recumbent with one arm abducted, Trendelenburg, lithotomy, lateral, and prone. The safety and physical comfort of the patient are emphasized, and the film shows evidence of good planning. The film might also have demonstrated the importance of talking with the patient and reassuring him, in those cases where he is positioned prior to the induction of anesthesia, but this is a minor criticism. The photography is good, and the film could be shown to nursing students who are having their first experience in the operating rooms. It could also be shown to graduate nurses, either in an orientation program planned for the operating room or in a postgraduate course of study.

Transporting the Patient for Surgery: 16 mm., color, sound, showing time 15 minutes. Presented by the American Nurses Association and the National League for Nursing Film Service in cooperation with the American College of Surgeons. Produced in 1958 by and procurable on loan from American Cyanamid Company, Surgical Products Division, 1 Casper St., Danbury, Conn.

This film demonstrates the coordinated responsibilities, interdepartmental and intradepartmental, of the hospital in providing safe transportation for the patient. Those concerned are the operating room nursing staff, the anesthesiology staff, and the nursing staff assigned to the patient unit. The method of procedure may vary with the facilities available in a hospital; however, the basic principles of safe transportation are applicable. An especially good feature of this film is its emphasis on the nurse identifying the patient and assisting him to the stretcher bed. The actress playing the nurse in the recovery room has an especially pleasant expression and conveys a feeling of genuine interest in the patient. The safety and comfort of the patient are correctly emphasized, and the photography is good. The narration is rather monotonous, but the content of the description is good and the narrator does not appear to be reading. The film is recommended for showing to student and graduate nurses and also to aides and orderlies.

Al in the Hospital: 16 mm., black and white, sound, showing time 22 minutes. Produced in 1950 by and procurable on purchase ($120) from Robert Disraeli Films, 206 E. 17th St., P. O. Box 343, Cooper Station, New York 3.

The story begins in the classroom where Al's chair is empty because he is in the hospital. His classmates write him a letter which the teacher delivers. At the request of his classmates Al makes drawings of his experiences. He tells about the bicycle accident which resulted in a broken leg and explains about x-rays, his cast, and the daily hospital routine. Hospital procedures such as a blood test and an injection are shown. Most of the film is narrated by a boy about 8 years of age and would appeal to children of this age group. Its purpose is to allay the fears of children who might be hospitalized; however, only the pleasant things are shown such as the competent nurse's care and the play room. The film is rather long, but it should be useful for showing to children and their parents.

Stapes Mobilization and Fenestration of the Oval Window for Otosclerotic Deafness: 16 mm., color, sound, showing time 21 minutes. Prepared by Samuel Rosen, M.D., New York. Produced in 1958 by Sturgis Grant Productions, New York, and procurable on loan from Samuel Rosen, M.D., 101 E. 73rd St., New York 21.

The surgical procedures of mobilization and fenestration are adequately explained in this film by drawings and diagrams and beautifully demonstrated by pictures of the actual surgery. The presentation of the anatomy, physiology of the conducting mechanism, and pathology of stapes ankylosis in the film is too brief for teaching purposes, and its value would be enhanced if more time were given to presentation of the problem. Some reference to the history of "mobilization of the stapes" and results obtained by this procedure before the turn of the century would also heighten the teaching value.

The three stages or types of operation used by the author are clearly demonstrated. The advisability of the first and third types of operation, however, is open to question in the light of the experiences of others. The first type has been discarded by many surgeons because of the danger of fracturing the crura. Also, there have been occasional injuries to the facial nerve in the hands of unskilled operators. The third procedure, fenestration of the foot plate, has been objected to by some surgeons because of failure to obtain useful hearing improvement, rapid loss of any hearing gain obtained, and possible increase in danger of injury to the inner ear. The explanation offered in the film for the gain in hearing from the third procedure is obviously deficient and does not agree with known facts concerning the effect of interruption of the ossicular chain on the hearing of air-conducted sound. Although the conditions which occur here have never been exactly duplicated, it appears that there is some clinical evidence to support the claim that improvement in hearing can be obtained by fenestration of a fixed stapes with the drum membrane intact. Further evidence is needed, however, in order to assess definitely the value of this procedure and either corroborate or disprove the claims made by the author.

The presentation of the problem for which this type of surgery is carried out is inadequate and should be improved, if the film is to be of optimum value in general medical teaching. The photography and recording of the actual surgical procedures are excellent, even though the scientific validity of the interpretations leaves something to be desired. It would have been preferable to indicate clearly that the hearing improvement from fenestration of the foot plate is not yet completely understood.

A Complete Office Gynecological Examination: 16 mm., color, sound, showing time 16 minutes. Prepared by Frederick J. Hofmeister, M.D., Milwaukee. Produced in 1958 by and procurable on loan from Frederick J. Hofmeister, M.D., 2212 W. State St., Milwaukee.

This film demonstrates the author's concept of what constitutes a complete gynecologic examination, and it emphasizes the fact that this must be a complete physical examination and demonstrates the examination of the breasts as an essential phase. Examination of the genitalia includes the Papanicolaou smear, endometrial biopsy, rectovaginal-abdominal examination and, where necessary, a cervical biopsy (which is demonstrated). Breast examination and the various methods of smear and biopsy for both cervix and endometrium are correctly shown. The photography is excellent and the film is recommended for postgraduate teaching of physicians, medical students, and nurses.

A Technique for Measuring Minimal Social Behavior: 16 mm., color, sound, showing time 12 minutes. Produced in 1957 by and procurable on loan from Veterans Administration, Central Office Film Library, Washington 25, D. C.

This is a filmed record of a schizophrenic patient being subjected to a newly devised psychological test. The procedure consists of observing the manner in which he enters the psychologist's office, picks up an ostentatiously dropped pencil, accepts a cigarette or a diagram of a crossed square, answers questions as to his orientations for time and place, and finally responds to a rather abrupt dismissal. The technique of scoring all this is not explained, but we are assured that the results differentiate specific degrees of "minimal social behavior." To an experienced viewer it might seem that the aloof, stereotyped, coldly inquisitorial method employed could well contribute to keeping the subject defensively withdrawn and autistic; perhaps deliberately, no attempt is made to explore his capacity to respond to human warmth or individualized communication. Possibly for the latter reason, some whimsical producer chose a musical background which uses themes derived mainly from Dukas' "The Sorcerer's Apprentice." The film is recommended only to those interested in a comparative study of psychological test procedures rather than in more searching samplings of normal and aberrant conduct.

NEW FILMS ADDED TO A. M. A. MOTION PICTURE LIBRARY

The following films were produced in 1958 as a public service by the Sears Roebuck Foundation in cooperation with the American Hospital Association and the University of Illinois Research and Educational Hospitals. All are in 16 mm., color, and sound. Procurable on loan (service charge $2.00 each) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., *Chicago 10.*

RX–A Prescription for Better Hospital Procedures
Showing time 25 minutes
The Flow Process Chart as Applied to Hospital Activities
Showing time 20 minutes
The Questioning Attitude as Applied to the Flow Process Chart
Showing time 19 minutes
The Right and Left Hand Chart as Applied to Hospital Activities
Showing time 23 minutes
Motion Economy as Applied to Hospital Activities
Showing time 22 minutes

This series of films is a clear demonstration of the method of planning and inaugurating a work simplification program. It illustrates some of the myriad hospital routines susceptible to such a program and should find application to other related medical centers such as clinics or other types of offices with multiple health programs and procedures. The most impressive thing about this series of related films is that they were made with actual participants in the programs instead of professional actors. An important feature of the series is that it highlights the method of attack and illustrates the results with several lucid examples. Since work simplification is a continuing responsibility of overworked medical personnel, these films should afford a provocative stimulus on a "do it yourself" basis.

(Note: The first film in the series—RX–A Precription for Better Hospital Procedures—was reviewed in THE JOURNAL of April 26, 1958, p. 2216.)

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

The Etiology of Hyperostosis Cranii (Metabolic Craniopathy): A Clinical Study. J. E. Caughey. J. Bone & Joint Surg. 40B:701-721 (Nov.) 1958 [London].

Hyperostosis cranii or metabolic craniopathy is a syndrome characterized by thickening of the inner table of the skull, which is more usual in the frontal region but may also occur over other parts of the skull, including the basal bones and the orbital plate. There may be generalized thickening of the whole cranium. In the frontal region especially the inner surface of the skull may become nodular, and it may attain a depth of ½ in. (1.27 cm.). This thickening consists of spongy bone containing large numbers of osteoblasts, and the underlying dura is usually thickened and adherent. A review of the literature has revealed that hyperostosis cranii is associated with several clinical states, such as the Stewart-Morel syndrome, acromegaly, and dystrophia myotonica, and it may also occur as "senile hyperostosis." Most workers who have studied the syndrome of hyperostosis cranii have noted the overwhelming occurrence among women. Dystrophia myotonica, a heredofamilial disorder of which hyperostosis cranii is one of the variable and common features, however, occurs equally among men and women. In a small but convincing series of cases of dystrophia myotonica, hyperostosis cranii was also found distributed equally among men and women.

The causation of hyperostosis is still a matter for speculation. More recent studies have focused attention on the endocrine system, and it seems probable, in view of the sex distribution in dystrophia myotonica, that the key to the problem may be found in this disorder. The author studied 50 patients with fully developed dystrophia myotonica, and the cases of 9 of these patients belonging to 6 families are reported in detail. The characteristic skull changes in these patients were hyperostosis cranii, a small pituitary fossa, excessive sinus formation, and prognathism. These changes in the skull may be described as acromegaloid. Gonadal atrophy was a common feature, and endocrine studies suggested that the endocrine defect is primarily a failure of the androgenic function of the adrenals and the testes. In rodents and in man ablation of the gonads leads to overactivity of gonadotrophic cells and, at times, of somatotropic cells. Sometimes pituitary tumors develop. Acromegaloid features may occur in eunuchs, and it is likely that the acromegaloid changes in patients with dystrophia myotonica are of the same order from overactivity of growth hormone. In animals excess of growth hormone produces thickening of the skull. In dystrophia myotonica, acromegaly, and the Stewart-Morel syndrome it is suggested that hyperostosis cranii is an expression of unrestrained activity of growth hormone.

Reduction of Serum Cholesterol in Hypercholesteremic Patients: Effect of a Polysorbate 80-Choline-Inositol Complex. H. L. Fuller. Maryland M. J. 8:6-13 (Jan.) 1959 [Baltimore].

The difficulty in controlling hypercholesteremia by diet alone indicates that some adjunct to diet would be of value. A number of agents have been studied and proposed for the control of hypercholesteremia. Among these are lecithin, lipotropic agents, estrogenic substances, vitamin B factors, pyridoxine, nicotinic acid, plant sterols, beta-sitosterol, vitamin E and wheat germ oil, polysorbate 80 complex, and unsaturated fatty acids. The author undertook the study of a polysorbate 80 complex in the management of hypercholesteremic patients. Patients were chosen from private clinical practices, general hospital outpatient departments, and chronic geriatric institutions. The subjects were known either to be obese or to have cardiovascular and peripheral vascular disease, diabetes, and hypothyroidism (idiopathic or postoperative myxedema). The serum cholesterol levels were determined. Of the 200 patients screened, 41 were selected who had serum cholesterol levels over 300 mg. per 100 cc. Their cholesterol values ranged from 300 to 1,460 mg. per 100 cc. Seventeen were women, and 24 were men. Their ages ranged from 33 to 66 years. The diabetics included in the study were well controlled, and their diet was deliberately unchanged while they were under observation. The hypothyroid patients maintained an euthyroid state with adequate doses of thyroid hormone. The patients with cardiovascular disease were all in

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

fairly good state of health, without evidences of congestive failure or histories of previous thromboembolic phenomena or vascular accidents. Rigid dietary restrictions had failed to induce significant reduction of serum cholesterol levels.

After determining the fasting serum cholesterol levels on 2 separate occasions, a week apart, treatment with polysorbate 80-choline-inositol complex (Monichol) was begun. The mixture was administered in doses of 10 cc. twice daily, and in some patients it became necessary to increase the intake to 40 cc., or even 60 cc. in 24 hours. All patients experienced a significant fall in serum cholesterol; in general, the higher the initial level, the greater the reduction achieved. Normal cholesterol levels could be maintained only by uninterrupted continuance of therapy. A sense of well-being was described by many of the patients. No significant side-effects were encountered. The long-range effect of reducing hypercholesteremia, particularly with respect to the possibility of reducing arterial disease, remains to be established. In a patient with cholelithiasis of the cholesterin variety, the stones were observed to dissolve during the period of treatment with Monichol. The author feels that possibly the medication in conjunction with a rigid low-fat, low-cholesterol diet, administered for the purpose of weight reduction, was the answer, since 2 other women, with shadows in their cholecystograms, who were not placed on restricted diets, did not experience stone resolution. Further studies on this problem are now in progress.

Hemodynamic Effects of Atrial Fibrillation in Patients with Mitral Valvular Disease. B. Caini and M. M. Brunori. Sett. med. 46:395-401 (Sept. 30) 1958 (In Italian) [Florence, Italy].

Hemodynamics were studied in 80 patients with mitral valvular disease, 30 of whom had atrial fibrillation and the remainder sinus rhythm. Pulmonary arterial pressure was, on the average, lower in patients with atrial fibrillation than it was in those with sinus rhythm; it rose gradually and in proportion to the increasing degree of physical disability in patients with sinus rhythm. There was no significant difference in increased pulmonary arterial pressure among patients with atrial fibrillation and a high rate of physical disability, such as those in groups 3 and 4 according to the American Heart Association classification. The discrepancy in pulmonary arterial pressure among patients with atrial fibrillation of groups 1 to 4 (American Heart Association classification) was also less pronounced than it was among patients with sinus rhythm. Pulmonary capillary pressure was lower in patients with atrial fibrillation than it was in those with sinus rhythm. No patient with atrial fibrillation had a capillary pressure above 25 mm. Hg. Blood pressure within the right atrium in patients with atrial fibrillation was higher than it was in patients with sinus rhythm. The degree of dilatation of the left atrium in patients with atrial fibrillation was distinctly greater than it was in those with sinus rhythm. Thus, atrial fibrillation, which developed in the course of mitral valvular disease, has appreciably changed the hemodynamic state in this series of patients; it relieved the pulmonary hypertension but increased the hypertension in the right atrium and in the venous branch of the systemic circulation.

Thymoma and Hemopoietic Insufficiency. E. R. Fisher and F. D. Beyer Jr. A. M. A. Arch. Int. Med. 103:95-104 (Jan.) 1959 [Chicago].

The authors point out that the association of thymic neoplasms with myasthenia gravis is well recognized, but that the exact nature of this association is not clear. In recent years attention has been directed to the occurrence of thymic tumors in several other clinical disorders, notably hypoplastic anemia, agammaglobulinemia, and pituitary basophilism (Cushing's disease). This report describes the clinical and pathological features of a 68-year-old man, in whom a thymic neoplasm was associated with severe hypoplasia of the bone marrow and pancytopenia. Sixteen previously recorded cases of the association of a thymic neoplasm or hyperplasia and hemopoietic insufficiency are reviewed. Although absolute proof that the latter is directly caused by the thymic neoplasm is lacking, certain considerations suggest such a relationship.

In at least 2 previously reported instances, the thymic neoplasm clearly antedated the blood dyscrasia. Improvement in hemopoietic function was observed in 5 of the 8 patients in whom a thymoma was successfully resected. The failures after thymectomy do not necessarily refute the significance of this observation. It is conceivable that irreparable marrow changes may occur, preventing a satisfactory response. The delayed response observed in several instances suggests that death may result from intercurrent causes before sufficient time has elapsed for marrow regeneration. It is worthy of consideration that in some instances thymic remnants were overlooked at the time of operation. This possibility suggests that the thymus per se may be influenced by its neoplastic component to produce such an effect. Lastly, rarity of both thymoma and idiopathic hypoplasia of the bone marrow would suggest that their association is more than one of chance. The failure to obtain in the patient presented a history of exposure to chemical poisons or to find clinical or pathological evidence of hypersplenism, endocrine disorder, or hemolytic anemia substantiates the primary nature of the hemopoietic disorder encountered. The relatively small amount of irradiation received by this patient appears insufficient to have produced such an effect.

Pathological classification of thymic neoplasms is unsatisfactory, and the relatively noncommittal term "thymoma" has gained popularity. However, the association of these neoplasms with various disease states suggests that attention should be directed to morphologic variants in thymomas. Review of the previously recorded examples of thymoma associated with refractory anemia or pancytopenia, in which sufficient morphologic information was available, revealed the spindle-cell type of thymoma to be most frequent in this syndrome. The lesion in the patient of this report was also of this type. Attention is directed to the histological similarities of the spindle-cell thymoma and hemangiopericytoma.

Some Less Familiar Roentgen Manifestations of Intrathoracic Histoplasmosis. B. Felson. A. M. A. Arch. Int. Med. 103:54-62 (Jan.) 1959 [Chicago].

After the demonstration of close correlation between histoplasmin skin sensitivity and intrathoracic calcification in the population of the Ohio and Mississippi river basins, it was predicted that active histoplasmosis would be recognized with increased frequency. This prediction appears to have materialized. For the most part the roentgenologic manifestations of intrathoracic histoplasmosis fall into the following 3 main categories: (1) an acute disseminated form with miliary or small patchy densities diffusely distributed throughout the lungs, sometimes encountered in epidemics, (2) a localized pneumonic form, and (3) the solitary nodule ("coin" lesion, histoplasmoma) of chronic and asymptomatic nature. Each of these types may be associated with hilar and/or mediastinal lymph node enlargement, the so-called primary complex. The healing phase is commonly accompanied by the deposition of calcium in the pulmonary lesions and lymph nodes, though complete clearing of the lungs without calcification is not unusual. The persistent spherical focus, or histoplasmoma, may represent either the end-result of an earlier pneumonic infiltrate or a filled-in cavity and is generally considered inactive. It often contains a solid or laminated central core of calcification, best demonstrated by tomography.

In discussing some less familiar manifestations of histoplasmosis, the author first takes up fibrocavitary histoplasmosis, which was observed in his department at the University of Cincinnati College of Medicine and the Cincinnati General Hospital in 5 patients, who ranged in age from 38 to 76 years. Each had been hospitalized in a tuberculosis sanatorium, where the correct diagnosis was established. A positive histoplasmin skin test was found in 4 cases, and a positive tuberculin test in 3. The histoplasmin skin test is important if Histoplasma capsulatum is not found in the sputum. That the process was essentially fibrotic in nature was evident from the duration of the disease, the irregular, dense, and sometimes linear appearance of the infiltrate, and the contraction of the thorax with retraction of the hilar and mediastinal structures. Extensive cavitation was present in all cases. The cavities were generally large and multiple. In 3 patients the lesions progressed, in 1 they remained stationary, while in 1 marked regression occurred.

Another less familiar roentgenologic manifestation of histoplasmosis is enlarging histoplasmoma. This form is rare, since the vast majority of histoplasmomas remain unchanged over prolonged periods of observation, probably representing a spent form of histoplasmosis. Broncholithiasis, a sequel of long-standing histoplasmic lymphadenitis, is not so rare in the Cincinnati area, at least 12 cases having been observed in the past 5 years. Other sequelae of prolonged histoplasmic lymphadenitis are traction diverticulum of the esophagus, multiple histoplasmomas, the middle-lobe syndrome, and superior vena caval obstruction, the latter resulting from fibrous or calcific mediastinitis. In the endemic area histoplasmosis must be given serious consideration in all instances in which a diagnosis of pulmonary tuberculosis was formerly entertained.

The Varied Clinical Manifestations of Coxsackie Virus Infections: Observations and Comments on an Outbreak in California. R. B. Gordon, E. H. Lennette and R. S. Sandrock. A. M. A. Arch. Int. Med. 103:63-75 (Jan.) 1959 [Chicago].

The known Coxsackie viruses have been placed in 2 different groups on the basis of histopathological changes produced in the mouse. At the present time, there are at least 19 immunologically different viruses within group A and 5 immunologically different types within group B. The authors discuss epidemiologic and clinical observations incident to a large outbreak of Coxsackie virus infection in California, which was first recognized in and around Shasta County in the summer and fall of 1956. The outbreak was primarily one of pleurodynia, but cases of aseptic meningitis and of pericarditis and pleural effusion were also encountered. As far as the authors are aware, this is the first time that Coxsackie virus, group B, type 5 has been reported as a cause of epidemic pleurodynia. The Coxsackie group B viruses have previously been incriminated as a cause of myocarditis in infants. These viruses are now also incriminated as etiologically responsible for some cases of acute benign pericarditis. The data presented in this report show that infection with a single immunological type of Coxsackie virus, namely, group B, type 5, can give rise to a variety of clinical manifestations, such as epidemic pleurodynia, aseptic meningitis, pleurodynia with meningeal involvement, pericarditis, and, very probably, myocarditis.

Effect of Prednisone on the Capillary Permeability in Patients with Heart Disease Associated with Edema. F. Fontanini, P. L. Prati and A. Rivi. Sett. med. 46:401-405 (Sept. 30) 1958 (In Italian) [Florence, Italy].

The authors investigated the existence and the intensity of a possible property of prednisone to control capillary permeability, besides the known diuretic effect, in the course of its administration to patients with heart disease accompanied by decompensation. Fifteen patients with chronic insufficiency of circulation associated with edema received prednisone in daily doses of 0.5 mg. per kilogram of body weight for 5 days. Before the treatment began, an excessive transudation of fluid through the capillary walls was present in 10 patients and an increased loss of protein substances at stasis in 13. Permeability of fluid and of proteins was restored to almost normal values in most patients and was improved in the others. A better effect was observed on the capillary permeability of proteins than of fluid, because the loss of proteins was, on the average, slightly below the upper physiological limit, and the transudation of fluid was, on the average, slightly above that limit. Prednisone therapy in this series of patients corrected the anatomic functional disorder of the capillary permeability, regardless of the action of any hemodynamic mechanism. It is, therefore, an efficacious drug, used either alone or in combination with other cardiotonic drugs, in the treatment of patients with decompensated heart disease associated with edema, who become refractory to common therapeutic measures.

Time of Occurrence and Duration of Pain Periods in Patients with Duodenal Ulcers After Small Meals. H. J. N. Dekkers and J. W. Tjeenk Willink. Nederl. Tijdschr. Geneesk. 102:2368-2371 (Nov. 29) 1958 (In Dutch) [Amsterdam].

It is generally accepted that the pain of duodenal ulcer is the result of chemical irritation of the ulcer crater by peptic gastric juice or by hydrochloric acid. In earlier studies the authors had demonstrated that this pain occurs during evacuation of the stomach and not, as is widely assumed, when the stomach is empty, and that, therefore, the term "hunger pain" is not justified. They now describe studies they carried out on 139 patients with duodenal ulcers to ascertain the time and the duration of evacuation of the stomach after a small meal. Gastric evacuation was studied clinically in 98 patients and roentgenologically in 84. The test meal consisted of 70 Gm. of bread, 10 Gm. of butter, 30 Gm. of cheese, and 0.4 liter (about ¾ pint) of milk. Fractional titration of the stomach contents ascertained not only the emptying time but also the onset and duration of the pain periods. In 51 of the 84 patients who were subjected to roentgenologic examination, the emptying time of the stomach was measured first after only barium sulfate was given. Later all 84 patients were tested with a mixture of barium sulfate and the same type of food given for the clinical examinations.

The majority of the patients who were examined clinically required more than 5 hours to empty their stomachs; the majority of those studied roentgenologically required more than 6 hours, although barium sulfate alone had left the stomach in 3 hours. Periods of pain, when they did occur, commenced from 1 to 4 hours and ended from 3 to 5 hours after the meal in the clinically examined patients; they generally lasted from 1 to 2 hours. During the somewhat slower evacuation during the roentgenologic tests the duration of pain was more variable than during the clinical tests. In some of the roentgenologic tests the pain terminated more than 6 hours after the meal, but it still coincided with the evacuation. Pain never occurred after evacuation of the stomach was complete.

The Prognostic Value of Leukocyte Studies in Polycythemia Vera Treated with Radiophosphorus. C. F. Stroebel and D. G. Hanlon. Minnesota Med. 42:10-12 (Jan.) 1959 [St. Paul].

The authors studied the leukocytic activity, based on quantitative and differential leukocyte counts in the peripheral blood, in 212 patients with polycythemia vera who were treated with radiophosphorus (P^{32}) at the Mayo Clinic. The results of these studies allowed classification of polycythemia vera into 4 subdivisions, namely, simple polycythemia vera (in 68 patients), occult leukocytic polycythemia vera (in 69), gross leukocytic polycythemia vera (in 50), and leukemoid polycythemia vera (in 25). In the patients with simple polycythemia vera, the absolute leukocyte count (determined by multiplying the white blood cell count per cubic centimeter by the total blood volume per kilogram of body weight) was 10 or less circulating leukocytes per kilogram. Myeloid immaturity in the peripheral blood did not exceed 1%. In the patients with occult leukocytic polycythemia vera, the absolute leukocyte count exceeded 10 circulating leukocytes per kilogram, but the relative leukocyte count did not exceed 15,000 leukocytes per cubic millimeter. Myeloid immaturity in the peripheral blood did not exceed 1%. In the patients with gross leukocytic polycythemia vera, the relative leukocyte count was 15,000 leukocytes per cubic millimeter or more, but myeloid immaturity in the peripheral blood did not exceed 1%. In the patients with leukemoid polycythemia vera, myeloid immaturity was noted in the peripheral blood in excess of 1% of the differential leukocyte count. Leukocytosis was or was not present.

This fourfold classification was applied to the study of the remissions occurring in these patients as a result of treatment with P^{32}. The rate of failure of treatment was the same for both groups of patients with simple and occult leukocytic polycythemia vera, but the incidence of long remissions was much higher in the patients with simple polycythemia vera. The over-all picture of resulting status also showed a definite relation to the leukocytic types: the condition of 58 (85%) of the 68 patients with simple polycythemia vera remained relatively simple; that of 43 (62%) of the 69 patients who had initially the occult leukocytic type of the disease became and remained relatively simple, while the conditions of only 22 (42%) of the 50 patients with gross leukocytic polycythemia vera and of 7 (28%) of the 25 patients with the leukemoid type of the disease became and remained relatively simple in type. These findings showed that the fourfold classification of polycythemia vera is of some prognostic importance. When granulocytic hyperplasia is present, the incidence of therapeutic failure is higher, more P^{32} is needed for control, and the greater is the chance for the development of either a leukemoid state or an acute leukemia.

Massive Intraperitoneal Hemorrhage Due to Paracentesis. N. Hakim, W. Hasbrouck and R. K. Spiro. J. M. Soc. New Jersey 56:19-21 (Jan.) 1959 [Trenton].

The authors present the history of a 65-year-old woman who on admission gave the impression of (1) having rheumatic heart disease with auricular fibrillation, mitral stenosis, and insufficiency, (2) congestive heart failure, and (3) likelihood of digitalis intoxication and pelvic pathology. A diagnostic abdominal tap was made to determine the nature of the ascitic fluid. A no. 18 gauge needle was introduced into the left lower quadrant at a point 5 cm. below the umbilicus in the anterior axillary line. This was the only area free of operative scars and palpable organs. No fluid was obtained on penetration of the peritoneal space. Bleeding at the site of the skin puncture was greater than normally encountered, but it was easily stopped. One hour after this procedure the patient appeared to be apprehensive. Her skin was pale, cold, and clammy. The degree of abdominal distention was unchanged. The only new finding was tenderness at the site of paracentesis. Possible perforation of an aberrant blood vessel or spleen was suspected.

Forty-eight hours after paracentesis the abdomen was very tense, and an exploratory laparotomy was decided upon. Approximately 6 liters of hemoascitic fluid was aspirated from the peritoneal cavity. A large accumulation of blood clots (limited chiefly to the pouch of Douglas and the area of the previous uterine suspension) was also removed. Beneath the site of paracentesis was the area of a firm fibrinous clot, measuring 3 by 6 by 10 cm., which surrounded a dilated omental varix. There was no active bleeding. The postoperative course was uncomplicated. It is believed that the bleeding had stopped 6 to 8 hours after the diagnostic peritoneal tap, as substantiated by the stability of the hematocrit and the level of the hemoglobin after the initial drop. Possible hepatic dysfunction secondary to congestive failure may also have played a role in the hemorrhage. The antihemorrhagic drugs may have helped establish hemostasis. The subsequent symptoms of an acute "surgical abdomen" were probably the result of the intraperitoneal hemorrhage causing peritoneal irritation, increasing abdominal distention, traction on surgical adhesions, and localization of clots in the pelvic floor. It is suggested that the possibility of an intra-abdominal bleeding be considered one of the causes of shock after paracentesis in cases of portal hypertension and ascites.

Toxoplasmosis: Review of Toxoplasmosis in Connection with Report of an Apparently Congenital Case Diagnosed in an Adult. R. K. Westby. Tidsskr. norske lægefor. 78:1238-1240 (Dec. 15) 1958 (In Norwegian) [Oslo].

Toxoplasmosis occurs in both congenital and acquired form. In congenital toxoplasmosis, hydrocephalus is seen in about 80% of the cases and is due to obstruction of the cerebral aqueduct or the interventricular foramen on both sides. There are intracranial calcifications in about half of the cases. Chorioretinitis, found in 60 to 70% of cases, is usually central and bilateral; in an early stage it is exudative and proliferative, but it later passes into an atrophic stage. Depending on the extent of the pathanatomic changes in the cerebrum, a number of neurological changes occur. Generalized or local convulsions occur in 60 to 70% of the cases. There is almost always mental reduction, varying from the lightest to the severest degrees. Sometimes Toxoplasma organisms are demonstrable in the spinal fluid. Some patients die soon after birth, many have grave defects due to brain and eye injury, others have relatively few symptoms. Acquired toxoplasmosis may present an acute generalized form, acute or subacute meningo-encephalitis, febrile or afebrile lymphadenitis, and monosymptomatic and asymptomatic forms. In a man, aged 60 years, with diagnosis of congenital toxoplasmosis based on the clinical findings, there were hydrocephalus, intracranial calcifications, chorioretinitis, history of generalized convulsions soon after birth, and positive dye test. The dye test was positive in a low titer, which was to be expected so many years after active infection.

SURGERY

Recurrent Mitral Stenosis: An Increasingly Common Occurrence Due to Inadequate Mobilization of the Valve. C. P. Bailey and D. P. Morse. J. Internat. Coll. Surgeons 31:8-23 (Jan.) 1959 [Chicago].

Of 1,607 patients with mitral stenosis who underwent mitral commissurotomy by the older left-sided approach, there was recurrence of the disease in 44, as was proved either at reoperation or at autopsy. It appeared that the early operations performed on these patients enlarged the mitral orifice enough to give relief of symptoms, but this was not usually enough for objective evidence of relief of the obstruction as evidenced by a change in the size of the heart or disappearance of the diastolic murmur. Gradual reclosure of these scarred valves may take place over a period of years (averaging over 4 years in this series) without a recurrent attack of rheumatic fever.

It is now possible routinely to perform an operation for mitral stenosis that effectively returns the valve to a normal functional capacity. The new operation, for which the term "neostrophingic mobilization of the septal leaflet" has been coined, and which usually can be performed only by the right-sided thoracic approach, entails opening of both commissures to their full curving extent and well into normal flexible valve tissue, so that the new septal leaflet is freely hinged at its base. In addition, it is essential to establish complete bipolar separation of the cross-fused subvalvular chordopapillary structures. The usual size of the valve observed at operation is 1 sq. cm. or less. The average orificial size provided by the older left-sided approach, as determined by catheterization, was less than 2.5 sq. cm. By the new procedure one can obtain a valve area ranging from 4 to 6 sq. cm. in 80% of the patients, thus producing objective as well as subjective evidence of relief of the obstruction. In 50% of the patients the diastolic murmur has been abolished.

Cardiac Ventriculography in the Selection of Patients for Mitral Valve Surgery. J. F. Uricchio, J. S. Lehman, W. M. Lemmon and others. Am. J. Cardiol. 3:22-27 (Jan.) 1959 [New York].

In selecting patients for mitral commissurotomy, the authors employed cardiac ventriculography-left (a roentgenologic technique consisting of opacification of the left ventricle by direct transthoracic needle puncture) in 42 patients with isolated rheumatic disease of the mitral valve. Of these 42 patients, 28 with significant mitral regurgitation, proved at surgical intervention, had a significant degree of reflux opacification of the left atrium (varying from 2+ to 4+). Of the remaining 14 patients with significant mitral stenosis, proved at surgery, 9 did not have any reflux opacification of the left atrium, while the other 5 patients showed a slight degree of reflux opacification (1+). No deaths occurred among the 42 patients, and there was no appreciable morbidity in this group, although serious complications may occur if the test is not performed with care. The chief indication for cardiac ventriculography-left appears to be present in those patients in whom there is uncertainty as to the presence or absence of major mitral regurgitation and the exact degree of stenosis. Preoperative estimation of such regurgitation is important, because mitral commissurotomy without correction of the regurgitation will not benefit the patient.

Leuko-Erythroblastic Anaemia in Breast Cancer Treated by Hypophysectomy. H. Hortling, K. Malmio, G. A. Björkesten and L. Hiisi-Brummer. Acta med. scandinav. 162:387-396 (no. 5) 1958 (In English) [Stockholm].

The authors studied 42 patients with metastatic cancer of the breast, on whom hypophysectomy was performed because any other form of treatment hitherto used was refractory. In 8 of the patients leukoerythroblastic anemia was observed before the operation; in 7 of these the effect of the hypophysectomy could be evaluated, and they were followed up from 19 months to 5 years. Diagnosis of leukoerythroblastic anemia was established when the presence of normoblasts or macroblasts or an increased number of granulocytes, i. e., myelocytes or metamyelocytes, could be identified in the peripheral blood. In one patient the only hematological symptom was an increase in rod-like nuclear granuloblasts to an average of 10%. In 7 patients on whom sternal puncture was performed, cancer cells were found. Ordinary routine methods did not reveal any clear signs of hemolysis in any of the patients. The blood picture returned to normal after hypophysectomy in 3 of the 7 patients, whereas an obvious remission of the hematological abnormalities was observed in another 3; in 1 patient improvement of the blood picture resulted, but apparently the disease affected the liver and the patient died.

The effect of hypophysectomy was dramatic in an apparently hopeless situation in one patient whose history is described in detail. A 52-year-old woman experienced pain in the back as a first symptom of cancer of the breast. In September, 1955, a radical operation, with removal of the axillary lymph nodes, was performed. In October metastases were detected in 3 vertebrae; in addition, anemia was observed. Roentgen-ray treatment was given to the vertebrae, and roentgenologic castration of the ovaries was performed. A tendency toward anemia and leukopenia developed. Androgenic therapy was administered for 8 months. The blood values became normal in March, 1956, but in August a rapid aggravation of the general condition and a deterioration in the blood picture occurred. Cortisone was given for 3 weeks, and hypophysectomy was performed in September. Five weeks after the operation an obvious improvement began, and the patient was practically free of symptoms until April, 1958, when a progressive leukoerythroblastic anemia developed again and death occurred in August. The authors' observations suggest that in cases of mammary cancer metastases in the bone marrow, with resultant leukoerythroblastic anemia, a remission may be attained by hypophysectomy when other types of treatment, including endocrine therapy, have failed.

Contribution to Reoperations on the Bile System (Causes, Indications, Results). B. Kourias, A. Sapkas and C. Athanassakos. Chirurg 30:1-10 (Jan.) 1959 (In German) [Berlin].

Of 1,432 patients with cholecystitis, who were operated on in the surgical clinic of the Greek Red Cross Hospital in Athens and in other hospitals in Greece between 1945 and 1958, 922 had a cholecystectomy performed, 384 underwent cholecystectomy and drainage of the common bile duct, 36 had an anastomosis between the common bile duct and the duodenum, 65 underwent cholecystostomy, and 25 had miscellaneous operations. Thirty-six (2.51%) of the 1,432 patients had to be subjected to reoperation for serious postoperative conditions from 40 days to 12 years after the first operation. Of these 36 patients, 22 (61%) had had their first operations performed at the Greek Red Cross Hospital in Athens, and 14 (39%) had been operated on in other hospitals in Greece.

The patients were subdivided into 9 groups according to the pathological condition which made reoperation necessary. The first group consisted of 22 patients (63%) in whom stones had remained in the common bile duct; 8 of these had undergone a cholecystectomy as the original operation, and 14 had had a choledochotomy. Considering the total number of 1,432 patients operated on, stones had remained in 1.1% of those who had undergone cholecystectomy and in 3% of those who had undergone choledochotomy. In half of these patients the stones were located in the hepatic or intrahepatic ducts. Omission of careful exploration of the common bile duct for stones, omission of cholangiography or manometry, the presence of a pseudodiverticulum or pouch of the common bile duct, lithiasis of the hepatic and intrahepatic ducts, early interruption of the original operation because of the patient's reduced tolerance, and congenital anomalies of the hepatic and bile ducts were found to be the causes for the postoperative remaining of stones.

Regarding the other groups, the second consisted of 2 patients with functional disturbances of the sphincter of Oddi; the third consisted of 2 patients with a cicatricial stricture of the ampulla of Vater; the fourth consisted of 2 patients with chronic pancreatitis; and the fifth consisted of 3 patients with traumatic or phlegmonous stricture of the hepatic and common bile ducts. Groups 6, 7, and 8 consisted of one patient each, with disturbances caused, respectively, by leaving the stump of the cystic duct too long, aneurysm of the hepatic artery, and a hydatid (echinococcus) cyst in the liver. The 9th and last group consisted of 2 patients who underwent exploratory operations for erroneously suspected stones.

Reoperation consisted of choledochotomy combined with removal of stones and drainage, choledochoduodenostomy, dilatation of the ampulla of Vater, sphincterotomy, removal of newly formed gallbladder, hepaticojejunostomy, transjejunal dilatation of a previously performed hepaticojejunostomy, removal of an echinococcus cyst, and exploratory laparotomy. There were 3 operative deaths (an operative mortality rate of 8.5%), and 2 patients died later. Of the 31 surviving patients, 30 (more than 90%) were in excellent health 6 months to 13 years after reoperation, and 1 was lost to follow-up. All the reoperations were performed with the aid of cholangiography and occasionally with manometric control.

Pancreatico-Gastrostomy in Pancreatico-Duodenal Resection for Carcinoma of the Head of the Pancreas or the Papilla of Vater. E. Millbourn. Acta chir. scandinav. 116:12-27 (no. 1) 1958 (In English) [Stockholm].

The author performed pancreaticogastrostomy on 7 patients for a malignant tumor of the head of the pancreas or the region of the papilla of Vater. The operations were performed in the department of surgery of the Centrallasarettet in Kalmar, Sweden, in 1947 and 1948. After pancreaticoduodenal resection, the distal end of the stomach was opened through a transverse incision made in its posterior wall, and the stump of the pancreas was brought into the stomach with the aid of long mattress, "stay" sutures. The whole cut surface of the pancreatic end was then secured with interrupted silk sutures into the stomach, through the incision in the posterior wall. The first row of sutures was made from the inside and the second from the outside of the stomach. When possible, omentum was fixed around the pancreaticogastrostomy. A large rubber drain, with side-openings and containing a smaller rubber tube for intermittent suction, was placed in the bottom of the operation area through a stab wound below the right costal margin, proximal and distal to the pancreaticogastrostomy, although not in direct contact with the suture line. In none of the 7 patients did pancreatic, jejunal, or gastric juice or bile ever occur in the fluid drained. The drain permitted early ambulation. Good healing without leakage or fistula formation in the pancreaticogastrostomy resulted in all the patients.

Pancreaticogastrostomy is somewhat easier to perform than pancreaticojejunostomy. Pancreaticogastrostomy permits repeated studies, even during a long postoperative course, of the excretory function of the pancreas and at the same time of the patency of the stoma. If amylase and trypsin activity is shown in the gastric juice (saliva being always removed by suction during the amylase determinations), the stoma must be patent if no aberrant pancreatic tissue is present in the stomach or in the nearest portion of the jejunum. Trypsin determinations give more reliable information than amylase determinations. In all 7 patients, the surgical intervention created a patent anastomosis for varying periods. In 3 patients, who survived the radical operation for periods varying from 9 months to 2 years and 7 months, the patency of the anastomosis was revealed at autopsy, and in 2 other patients the patency was revealed by trypsin determinations of the gastric juice 2¼ and 3½ years, respectively, after the surgical intervention. The anastomosis thus remained patent for several years even though the pancreatic duct was small at the surgical intervention. Postoperative obliteration occurred about 2 years after radical surgical intervention in one patient. Reoperation with a new pancreaticogastrostomy (side-to-side) was successfully performed 2 years and 9 months after radical resection.

In none of the 7 patients did the flow of the pancreatic juice into the stomach give rise to subjective discomfort. They did not complain of dyspepsia, and the stools were normal so long as the pancreaticogastrostomy was patent. Postoperative examination of the gastric juice showed achlorhydria in the 6 patients who most recently underwent pancreaticogastrostomy. This postoperative achlorhydria probably was the result of pancreatic juice emptying into the stomach, and it is to be considered an important factor in the avoidance of ulcer formation in the gastrojejunal stoma. Pancreaticogastrostomy is recommended in radical pancreatic resection instead of pancreaticojejunostomy, despite the limited number of patients reported on.

Rapid Relaxation of the Right Atrium in the Treatment of Cardiac Arrest Occurring in the Course of Surgical Operation. F. Morino and R. Gentilli. Minerva chir. 13:1309-1320 (Nov. 30) 1958 (In Italian) [Turin, Italy].

The authors report on 2 patients who suffered cardiac arrest during the course of a surgical operation. The heart was reactivated in both patients by causing a rapid relaxation of the right atrium. In the first patient, an 8-year-old child, arrest of the heart occurred while an attempt was being made to isolate the aorta. No result was obtained by injecting epinephrine and massaging the heart for about 10 minutes. Inasmuch as a marked distention was noticed in the walls of the myocardium, a syringe with a large needle was introduced into the right atrium, and the distention was relieved momentarily by extracting rapidly 50 cc. of blood. Massaging the heart was then started at once, and after a few rhythmic compressions the heart started pulsating spontaneously. After 15 minutes of rest the operation was continued and was completed without further incident. In the second patient arrest of the heart occurred in the course of opening the pericardium. The heart beat was restored after extracting 50 cc. of blood from the right atrium and massaging the heart. The operation was continued after a 20-minute rest and was completed with no further complications.

Sarcoma of the Stomach. B. Thorbjarnarson, J. M. Pearce and J. M. Beal. Am. J. Surg. 97:36-42 (Jan.) 1959 [New York].

The authors report on 50 patients, between the ages of 16 and 79 years, with sarcoma of the stomach who were treated on the pavillion service of the New York Hospital between 1932 and 1958. Of the 50 patients, 37 had lymphoma, 11 had leiomyosarcoma, 1 had myxosarcoma, and 1 had fibrosarcoma. During the same period, 670 patients with malignant neoplasms of the stomach were observed, so that sarcoma represented 7.4% of all malignant lesions of the stomach. Pain, weight loss, and bleeding were, in order of frequency, the most common symptoms. The clinical and laboratory findings seldom led to the correct diagnosis before surgical intervention. Thirty-two of the 37 patients with malignant lymphoma of the stomach were subjected to definitive surgical removal of the neoplasm. There were 2 deaths after the surgical intervention, representing an operative mortality rate of 5.4%. Thirteen patients survived for 5 years or longer. Since 28 of the 37 patients were admitted to the hospital before 1953 and 24 of these were subjected to definitive surgical removal of the neoplasm, the 13 patients represented 59% of those who were eligible for computation of 5-year survival rates.

Of the 13 patients with other sarcomas than lymphoma of the stomach, 12 were subjected to surgical intervention. There was one postoperative death. Six patients survived for more than 5 years; one died of recurrence 6 years after the operation. Thus, of the entire group of 50 patients, 19 patients survived for 5 years or longer. The prognosis for patients with sarcoma, therefore, is considerably better than for those with carcinoma. Roentgenotherapy is recommended for patients with lymphoma of the stomach but not for patients with other types of sarcoma of the stomach.

Strangulated Femoral Hernia: A Review of 170 Cases. F. A. Rogers. Ann. Surg. 149:9-20 (Jan.) 1959 [Philadelphia].

A femoral hernia is more likely to undergo acute incarceration and subsequent strangulation than any other common hernia. Strangulation constitutes an urgent surgical emergency. Acute incarceration occurs more frequently in this type of hernia because the small femoral ring, through which the herniation occurs, is more rigid and because herniation through the defect occurs in a more vertical or downward direction. It is this latter factor, uniquely characteristic of the femoral canal hernia, which contributes to the difficulty in reducing it. This study on acutely incarcerated and strangulated femoral hernia was undertaken primarily to discover the results of treatment.

The data from clinical charts of 170 patients treated over a 15-year period on the College of Medical Evangelists surgical service at the Los Angeles County Hospital were tabulated by I.B.M. machine. The group included 116 women and 54 men, 71% of whom were in the age decades of 60 to 90 years. Eight of the 105 patients who knew that they had a hernia had had previous incarcerations. Most of the 12 deaths in this group could have been prevented by elective repair of the hernia. The diagnosis of hernia was made for the first time in 61 of the patients. Vomiting is a prominent symptom. A mass in the femoral region is the most important single physical finding. Acute strangulation of a femoral hernia is a common cause of acute intestinal obstruction among patients more than 50 years of age. When intestinal colic associated with vomiting suggests acute intestinal obstruction, hernial orifices should be carefully examined for the presence of a mass. A femoral hernia and an incarcerated inguinal hernia can be differentiated. The femoral hernia is palpable below and lateral to the pubic spine, while the inguinal hernia is found to lie superiorly and medially to the pubic spine.

In the series reported, when the correct diagnosis was made early, the over-all mortality was low. When the patients had been admitted to hospital services other than general surgery and the proper diagnosis was delayed, the mortality reached 50%. The incidence of gangrene rose sharply as the delay in diagnosis increased. Delay in surgery for any reason greatly increased the number of deaths. Many patients reached the hospital in shock. Others had suffered fluid and electrolyte loss and required replacement therapy before operation could be carried out. An adequate surgical approach is important, and the excellence of the Cheatle-Henry extraperitoneal, retropubic operation is emphasized. The over-all mortality rate for this series was 13%. The male operative mortality was 20%, while that of female patients was only 10%. Thirty-five patients required resections of gangrenous portions of the small intestine; there were 9 deaths in this group. Postoperative complications occurred in 37 patients, and there was a 6.6% wound infection rate. An elective repair of all femoral hernias is advisable.

The Value of Intra-Articular Injections in Osteoarthritis of the Knee. J. H. Miller, J. White and T. H. Norton. J. Bone & Joint Surg. 40B:636-643 (Nov.) 1958 [London].

The authors report on 59 men and 122 women with osteoarthritis of the knee treated by intra-articular injections. The 181 patients were accepted for treatment, provided that pain was present when treatment was begun and was not showing any tendency to subside, that positive roentgenologic evidence of osteoarthritis was present, and that treatment had not been given previously. Three solutions, chosen as typical of those in common use, were employed for injections, namely, lactic acid solution, procaine (Novocain) hydrochloride solution, and hydrocortisone solution. Isotonic sodium chloride solution and mock injection (given with a special syringe, with which neither air nor fluid could be injected into the joint, although the same visual effect was produced by this device as by fluid) were used for control purposes. Each patient was allotted 1 of the 5 types of injection at random, and the same type of injection was used throughout his or her treatment, which consisted of 5 injections at intervals of 2 weeks. Each patient was reviewed on 2 occasions, 6 weeks and 6 months after the end of the treatment.

Irrespective of the type of injection used, including the controls, no significant difference in the effects was demonstrated in the results. From the point of view of the assessing physician, there was found an appreciable objective improvement, which was fairly evenly distributed. Presumably, this indicates a more natural and confident use of the joint, and is a reflection of the change in outlook of the patient after the injections. The objective assessment also showed that the percentage of improvement was higher among men than among women. Between the men and the assessor agreement was almost complete, but more women expressed satisfaction than the assessor was prepared to accept on clinical grounds. The inference is that women are more susceptible to suggestion in this form of treatment, and here again the psychological element must be taken into account.

Most patients in each group expressed satisfaction with their treatment. This does not depend at all on the injection of any particular substance into the joint, but rather on the psychological atmosphere created. The use of joint puncture can, therefore, be accepted as a reasonable placebo in the care of osteoarthritis. It follows that, if puncture is decided upon, the least noxious and most economical substance (isotonic sodium chloride solution) or none at all (mock injection) should be used.

The Environmental Distribution of Staphylococcus Aureus in an Operating Suite. R. I. Wise, F. J. Sweeney, G. J. Haupt and M. A. Waddell. Ann. Surg. 149:30-42 (Jan.) 1959 [Philadelphia].

At the Jefferson Medical College Hospital in Philadelphia an attempt was made to determine the presence and extent of contamination by staphylococci in the operating rooms and to detect the source and mode of entry of the pathogenic bacteria into clean surgical wounds. All the material for bacteriological investigation was collected during 71 operative procedures. A total of 1,096 cultures were obtained in 5 days. This number included 206 nasal cultures, which were obtained by moistening swabs with nutrient broth and introducing a swab into the anterior nares of every person entering the operating rooms. It was found that members of the hospital staff who had close contact with infected patients had a greater incidence of coagulase-positive cultures of staphylococci isolated from the anterior nares. Many different bacteriophage types of Staphylococcus organisms were detected in the anterior nares of the 136 persons who entered the operating rooms during the 5 days from Aug. 13 to Aug. 17, 1956. Five of these types were known to cause postoperative wound infections during the period from July 1 to Oct. 31, 1956, and were isolated from 13% of the personnel. Other strains were isolated which were not implicated in any infection during the period.

Staphylococci were isolated from the interior of 90% of 481 surgical gloves at the conclusion of the surgical procedures. The mean bacterial count was 4,212 per glove. Coagulase-positive staphylococci were isolated from 14% of the gloves, but none of the strains from gloves was susceptible to bacteriophage. Approximately 10% of the surgical gloves were punctured or torn during surgery. Coagulase-positive staphylococci were isolated from 11% of samples of skin obtained from the edge of incisions, from 8% of samples of solution used in rinsing instruments during surgery, and from 17% of surgical incisions which were cultured just prior to closure. These strains, with 2 exceptions, were not typeable with bacteriophage. Various fomites, such as talcum powder, rubber drains, tubes, soaps, brushes, and surgical packs, were found to have a low incidence of viable bacteria. The air of the operating rooms contained chiefly staphylococci but mixed with other bacteria. The contamination of the air became greater as the number of persons in the room increased. None of the cultures of coagulase-positive staphylococci obtained from the air was typeable with bacteriophage.

Infections of deep surgical wounds developed in 2 of the 71 patients in this series. In both instances coagulase-positive staphylococci were isolated from the infectious processes, but the cultures were not typeable with bacteriophage, and so it was not possible to trace the source of these infections. The authors stress the need for rigid aseptic techniques to prevent hospital personnel from becoming carriers of pathogenic bacteria and from spreading these bacteria to susceptible hosts. The prophylactic use of antibiotics cannot be substituted for aseptic techniques, since the strains causing the infections are usually resistant to the action of the commonly used antibiotics.

The Management of Pathological Fracture of the Major Long Bones from Metastatic Cancer. R. A. Bremner and A. M. Jelliffe. J. Bone & Joint Surg. 40B:652-659 (Nov.) 1958 [London].

The authors report on 40 patients (29 women and 11 men) with disseminated cancer. Thirty-three of these patients had 36 pathological fractures of the long bones (double fractures having been sustained by 3 patients), for which they were treated by internal fixation and irradiation, and 7 patients received the same treatment for "prophylactic" reasons, since they had destructive lesions of the long bones from metastatic cancer. Nineteen of the 40 patients had cancer of the breast; 8 had bronchial carcinoma; 13 had carcinoma of the thyroid, carcinoma of the rectum, epithelioma of the scalp, malignant angioendothelioma of the nasopharynx, carcinoma of the kidney, carcinoma of the esophagus, and multiple myelomatosis, respectively; and in 3 the site of the primary tumor was undiscovered. Of the 43 lesions, the neck and trochanteric region of the femur was involved in 19, the upper third of the shaft of the femur in 10, the middle third of the shaft of the femur in 8, and the humerus in 6.

All the patients were treated by internal fixation at the earliest opportunity, either by an intramedullary nail or in the case of some lesions near the subtrochanteric region, where an adequate grip could be obtained for plate screws below the lesion, by a nail and plate. All were also given irradiation therapy, and, when intramedullary fixation had been employed, the whole length of the involved bone was irradiated. Excluding the patients treated "prophylactically," 25 (83%) of the 30 patients who had sustained a fracture of the lower extremity survived for more than 6 weeks, and all returned to walking with crutches; union occurred in 80% of these fractures. Four of the 5 patients who had sustained a fracture of the humerus survived to regain a functionally useful arm, and 3 of the fractures united. "Prophylactic" internal fixation and irradiation therapy appeared to be helpful in 5 of the 7 patients.

The danger of disseminating tumor cells, either generally or locally, is the main criticism of this method of treatment. In those patients in whom irradiation therapy was used to cover the whole of the operation area, there was no evidence of spread into the soft tissues locally or along the medullary canal. Internal fixation might not be justified in the treatment of a single metastasis from a primary tumor of low-grade malignancy carrying a prognosis of several years, but, in general, the theoretical dangers of dissemination may be ignored. The difficulties of the technique are easily surmountable and have probably been overemphasized in the past. Internal-fixation and irradiation therapy is the best method at present available for dealing with the difficult problem of management of a pathological fracture of a major long bone through a metastatic cancer deposit.

Some Comments on the Treatment of Fractures of Long Bones in Children (With Special Reference to 3,594 Cases). J. Desbrosses, J. Rebouillat, C. Bosser and M. Guilleminet. Presse méd. 66:1929-1930 (Dec. 6) 1958 (In French) [Paris].

Conclusions are drawn from a large collection of statistics gathered from 3,594 cases on the infants' surgery service of Debrousse Hospital and at the orthopedic and infant surgery clinic of Edouard Herriot Hospital in Lyons. The authors have sought to show the respective parts that manual reduction and surgical methods play in fractures of the long bones in children from 1 to 15 years old. They particularly noted the predominant incidence of location of fractures in the upper extremity, fractures being located in this extremity in 2,742 out of 3,594 cases (or 70.2%). The upper extremity was chiefly affected at the level of the forearm (1,364 cases) and at the elbow (797 cases). In the latter case, surgical reduction was often required, not essentially for reasons of the immediate subsequent vasculonervous complications but on account of the functional future, which might be heavily compromised by a defective bone alignment, an antibrachial abutment, or a stiffened joint. All juxta-articular or articular fractures in the child should be carefully reduced to avoid severe hazards. Out of 126 cases of external condyle fracture, 32 were surgically reduced, or 25%, which is one of the highest operative percentages. Conservative management should be tried, but this occasionally proves inadequate, especially for the elbow, which in this study required operation in 18.3% of the cases.

According to the authors' findings, fractures are much less frequent in the lower extremity and are much less operable. The femoral diaphysis is the bone which is most often operated on. In this series, 11% of the fractures of this type were operated on (40 interventions out of 364 fractures), but this was an unusually large number owing to the particular circumstances. All fractures of the ends of the tibia were treated orthopedically, and only 24 fractures of the tibial diaphysis, out of 443 such fractures, had to be osteosynthesized. This study shows the authors' tendency first toward utilizing manual reduction of fractures and then toward having recourse to surgery in carefully chosen cases when it alone can have satisfying results. There was surgical reduction in 22.2% of the fractures of the upper extremity and in 7.7% of the fractures of the lower extremity in this series. The over-all percentage of fractures which were operated on was only 9.4% (340 out of 3,594 fractures).

Diverticula of the Duodenum (Contribution of Cases and Clinical Considerations). A. Jovine and G. Francini. Acta chir. ital. 14:743-771 (Sept.-Oct.) 1958 (In Italian) [Padua, Italy].

Nine patients with duodenal diverticula, observed at the surgical clinic of the University of Padua in the last 12 years, are reported on. Comparison of the data available from these patients and those available in the literature shows that duodenal diverticula are frequent but that most of the time they are asymptomatic. Only in a small number of cases have duodenal diverticula caused such disturbances as to make surgical intervention necessary. Roentgenologic examination was found very useful by the authors in studying the diverticular formations and the various other organs in which concomitant lesions could be present. Medical therapy is indicated unless surgical intervention is made necessary by major complications. Whether resection or invagination of the diverticulum must be performed is to be decided by taking into consideration the state of each patient. Palliative interventions, such as gastroenteroanastomosis, are indicated when resection or invagination may be too dangerous.

NEUROLOGY & PSYCHIATRY

Dystonia Musculorum Deformans Alleviated by Chemopallidectomy and Chemopallidothalamectomy. I. S. Cooper. A. M. A. Arch. Neurol. & Psychiat. 81:5-19 (Jan.) 1959 [Chicago].

The author reports on 16 children with advanced dystonia musculorum deformans, which has previously been demonstrated to be a progressive incapacitating disease of childhood, characterized by involuntary movements and deformities of the entire body. This disease has heretofore been considered to be unresponsive to medical, surgical, physical, or psychiatric therapy. The author subjected the patients to chemopallidectomy and/or chemopallidothalamectomy; in these operations well-localized but sufficient-sized lesions were accurately placed in the globus pallidus and/or ventrolateral nucleus of the thalamus. In 3 patients the operation was performed bilaterally. Thirteen of the 16 patients obtained marked alleviation of the involuntary movements and deformities of this previously intractable, progressive disease. The cases of 5 of the 13 patients, 2 boys, aged 16 and 18 years, and 3 girls, aged 12, 10, and 13 years, respectively, are reported on in detail, illustrating this alleviation. Such relief has now persisted for more than 2 years in several of these patients. The entity of dystonia musculorum deformans can no longer be considered as a hopeless, irreversible disease. Chemopallidectomy and/or chemopallidothalamectomy is the treatment of choice in alleviating it.

Therapeutic Possibilities During the Acute Stage of Heine-Medin's Disease (Poliomyelitis). H. Zischinsky. München. med. Wchnschr. 101:30-33 (Jan. 2) 1959 (In German) [Munich, Germany].

The author shows that an effective specific therapy is not available for acute anterior poliomyelitis. Treatment with serum of convalescents, with gamma globulin, or with antibiotics all proved ineffective. In view of the pathogenesis of poliomyelitis, an effective specific treatment is even theoretically impossible. Laboratory studies on a patient, whose history is presented, indicate that *viremia and invasion of the virus into the central* nervous system take place at a time when there is as yet no suspicion of poliomyelitis. For this reason therapy will always come too late, even if a specific therapy were available. Much can be done during the acute stage of poliomyelitis. Good nursing care is important. Paralysis of deglutition and respiration demands special measures. These are most effectively supplied in special poliomyelitis centers staffed with suitably trained teams and equipped with all instruments and devices for therapy and rehabilitation.

The Use of Ritalin in Psychotherapy of Depressions of the Aged. A. Jacobson. Psychiat. Quart. 32:474-483 (July) 1958 [Utica, N. Y.].

The author investigated the effectiveness of methylphenidate (Ritalin) hydrochloride, a new central nervous system stimulant and antidepressant, in facilitating psychotherapy in depressed patients of the involutional age group. Patients, including both those with reactive and those with involutional depressions, undergoing psychotherapy and simultaneously receiving Ritalin, were evaluated regarding changes in alertness, sense of well-being, dissipation of morning fatigue, cooperativeness in psychotherapy, and ability to function socially and otherwise. A placebo was substituted for Ritalin in a second comparable group of patients. Each group included 27 patients; all were in the 6th and 7th decades of life. Patients recognized as manic-depressive were excluded. Ritalin was given in doses ranging from 10 to 30 mg. 3 times in the first 8 hours of the day, at spaced intervals. All the patients were ambulatory and were considered fair-to-good subjects for extramural care, inasmuch as suicide was not believed an imminent threat.

The author's chief aim was effective psychotherapy, which is difficult in depressed patients because, by the very nature of their illness, they have difficulty in sharing their thoughts and feelings with others. It was his impression that Ritalin had a place in opening this communication barrier to effective psychotherapy. The drug facilitated communication and cooperation chiefly by its mood-elevating effects. The psychomotor stimulation was without significant effect on the blood pressure; furthermore, there was no depressive let-down as the effects of the drug wore off. Twenty-two of the 27 patients receiving Ritalin showed slight to marked improvement. Five patients showed no improvement and required hospitalization and/or electric convulsive therapy. Of the group of 27 patients who did receive a placebo instead of Ritalin, 11 showed minimal to moderate improvement; 16 required hospitalization and/or electric convulsive therapy. Four illustrative case histories are presented.

Ritalin appeared to increase the effectiveness of psychotherapy with elderly depressed patients. As *in an earlier paper, the author was impressed* by the increase in alertness, and the dissipation of early morning depression and fatigue and by the lack of evidence of addiction. The usefulness of Ritalin in counteracting the lethargy or oversedation of ataractic drugs was also mentioned.

Human Infection with Listeria Monocytogenes: Review of Main Features of Listeriosis. O. Jessen. Ugesk læger 120:1701-1707 (Dec. 18) 1958 (In Danish) [Copenhagen].

Human infection with Listeria monocytogenes is regarded as rare in Denmark, but the number of cases reported is thought not to reflect the true frequency. Both human and animal listeriosis is spread over the entire globe. The reaction of the organism to the bacteria is typical: there is either supuration, with a considerable number of mononuclear cells in the pus, or formation of miliary granulomas (listeriomas), with a central coagulation necrosis and peripheral accumulation of reticuloendothelial cells, leukocytes, and monocytes. The symptoms occur in different combinations, with transition forms. The 2 most important syndromes are presumably meningoencephalitis and the septic granulomatous form in infants. Clinically, meningitis due to L. monocytogenes is not distinguishable from other forms of bacterial meningitis. It may be preceded by a short prodromal stage. The further course is marked by meningeal and cerebral symptoms. The course is often violent; it may be subacute. In some cases the disease passes into a subchronic stage, with persistence of bacteria in the spinal fluid for months, and is clinically marked by neuropsychiatric symptoms and moderate fever. The peripheral picture is marked by neutrophil granulocytosis. Disseminated granulomatosis in infants (granulomatosis infantiseptica) is transmitted from mother to child in utero, perhaps now and then to the child during birth. In most cases of pregnancy listeriosis, a retrospective diagnosis is not possible. With signs of grave disease in the newborn infant, listeriosis should be considered. During the course of a localized infection, hematogenic spread may cause metastatic foci in practically every organ.

Early and adequate antibiotic and chemotherapeutic treatment has decisively improved the prognosis in listeriosis. The treatment must be continued for at least 10 days after disappearance of clinical symptoms. Excellent results have been attained with the tetrayclines. Treatment with penicillin, together with sulfonamides, has been effective in some cases, but seems less reliable. In the American literature erthromycin is recommended, especially combined with penicillin.

Dissecting Aneurysms of the Carotid Artery Following Arteriography. J. F. R. Fleming and A. M. Park. Neurology 9:1-6 (Jan.) 1959 [Minneapolis].

The authors report on a 58-year-old man and on a 32-year-old woman in whom a dissecting aneurysm of the common carotid artery occurred in the wall of the artery as a complication of percutaneous carotid arteriography at the site of needle puncture, with narrowing or occlusion of the arterial lumen. Carotid arteriography had been performed for a subarachnoid hemorrhage from a berry aneurysm on the right internal carotid artery in the man, and for a massive intratemporal lesion causing hemiplegia on the left in the woman. Both patients died, and autopsy was performed on both. In the man, the common carotid artery was narrowed sufficiently to provide massive cerebral hemorrhage. In the woman, the hemorrhage was small and was an incidental finding at autopsy. It is surprising how resistant the vessel wall is to the trauma of puncture. However, large autopsy surveys indicate that in a significant percentage of patients subjected to arteriography a small dissecting aneurysm may occur similar to that observed in the woman. Lesions large enough to occlude the lumen, similar to that which occurred in the man, are very rare, but a few have been reported. Nevertheless, even the smallest intimal elevation may become the site of thrombus formation and thus a possible source of emboli. The clinician should be alert to this complication which may explain certain postangiographic symptoms and may elucidate the interpretation of incomplete filling of the carotid artery in some cases. To prevent a dissecting aneurysm, which may be produced at either the puncture site or the site of perforation of the intima of the posterior wall of the artery, a short, beveled, perfectly sharp needle, as small in diameter as feasible, should be used.

PEDIATRICS

Neurological Involvement in Kaposi's Varicelliform Eruption: Clinical and Electroencephalographic Observations and Considerations. E. Cheli and G. B. Cavazzuti. Minerva med. 49:3961-3968 (Oct. 24) 1958 (In Italian) [Turin, Italy].

Neurological involvement was studied in 8 children, 5 to 12 months old, with Kaposi's varicelliform eruption. The eruption had been contracted by each child in the 3rd or 4th month of life. Fever lasted in each case from 6 to 10 days. Neurological involvement was evidenced by clinical symptoms in 3 children, by changes in the cerebrospinal fluid in 3 (by glycorrhachia in 2 and glycorrhachia, cytoorrhachia, and albuminorrhachia in 1), and by electroencephalographic changes in 2. Three of 4 children who showed neurological involvement on electroencephalographic studies showed no clinical symptoms of neurological involvement, and the spinal fluid was found to be normal. Electroencephalographic findings became normal in one week in 2 of these 3 children; some isolated delta waves, at average voltage, were still present after 12 days in the 3rd child. The authors believe that the neurological involvement in patients with Kaposi's varicelliform eruption is a specific expression of a generic ectodermotropism of the herpetic and vaccine virus causing various pathological manifestations, and that its minimal neurological manifestation can be detected only by means of electroencephalographic studies.

Virus Embryopathies. T. Hellbrügge. München. med. Wchnschr. 101:15-20 (Jan. 2) 1959 (In German) [Munich, Germany].

A review of the clinical, experimental, and embryologic knowledge on the virus embryopathies suggests that transplacental transmission of virus is possible at any time during pregnancy. The resulting damage to the fetus depends upon the stage of pregnancy during which the infection took place. During embryogenesis damage occurs to organs and organ systems that are in the developmental phase, and malformations result. These have their sites of predeliction, such as in the epithelial cells of the crystalline lens, in the sensory cells of the inner ear, in the ameloblasts of the dental primordia, and also in the heart and brain, that is, in cell systems characterized by an intensive nucleoprotein metabolism, which apparently provide favorable conditions for the growth of the virus. Damage produced by a virus has a definite phase specificity, for, regardless of the time of virus infection, it begins only during the stage of differentiation, which is connected with an increased cellular metabolism. This explains the involvement of one or several organs.

When infection is caused by viruses that act slowly, such as the rubella virus, the destructive processes continue for a long time, even after birth, whereas in the case of viruses that act with a sudden explosive effect the destructive processes are clearly evident a few days after infection. Virus invasions do not necessarily cause infections. For instance, if infection with rubella virus occurs during the first month of pregnancy, 25% of the infants show embryopathy. With virus infections in succeeding months of pregnancy, the prognosis for the fetus becomes more favorable, and, if they occur during the last months of pregnancy, the pathological changes in the fetus are similar to those that result from postnatal infection. The incubation periods of the most important virus diseases are listed, and it is suggested that women in the early stage of pregnancy should be isolated from children who either have virus diseases or are likely to be in the incubation period. Pregnant women are likely to forget virus infections that occurred very early during pregnancy, but will sometimes recall them, when the date of the last menstruation is fixed or the days of pregnancy are counted on which the intrauterine injury to eye or ear may have occurred.

Osseous Injuries in the Newborn. W. C. Mitchell and M. B. Coventry. Minnesota Med. 42:1-4 (Jan.) 1959 [St. Paul].

The authors report on osseous injuries in newborn infants observed at the Mayo Clinic. Trauma to the skeleton of the newborn infant is of interest to the family physician, obstetrician, and orthopedist. Primiparous mothers with difficult breech deliveries constitute the largest group with which injuries to the bones and epiphyses of newborn infants are associated. Torsion, traction, and digital pressure are the usual mechanisms of injury. The fracture may be induced deliberately to facilitate delivery of the infant. The newborn infant has such unique propensity for the formation of callus and healing of bones that nonunion is almost unknown. Shortening and angulation of even 40 to 50 degrees usually are corrected by subsequent growth. Consequently, masterful neglect may be legitimate therapy in certain osseous injuries occurring in newborn infants. Fractures of the shaft of the femur require active treatment, and Bryant's traction gives excellent results if used properly. The trauma of a difficult delivery may cause epiphysial or subperiosteal hemorrhage presenting clinical symptoms; however, roentgenologic evidence of injury may not be present until proliferative calcification occurs in the hematoma, which may take 5 to 7 days. Such injuries apparently all heal without residual deformity.

Acute Obstruction of Small Intestine Secondary to Hematoma in Children. A. L. Mestel, G. A. Trusler, S. A. Thomson and C. A. F. Moes. A. M. A. Arch. Surg. 78:25-32 (Jan.) 1959 [Chicago].

The authors report on a 9-year-old girl and an 8-year-old boy with acute obstruction of the small intestine secondary to hematoma. Both had a history of abdominal injury, and both had abdominal pain and vomiting. Laparotomy was performed on the girl and revealed a hematoma of the second, third, and fourth parts of the duodenum which was resected. The child recovered after an uneventful postoperative course. The boy had a history of an undiagnosed bleeding disorder, manifested by several prolonged bouts of bleeding due to trauma and minor surgery. On admission, the patient denied any recent trauma, but the next day it was ascertained that he had been struck in the epigastrium by the butt of a rifle while at play. A tube was passed into his stomach and attached to suction. Dextrose, sodium chloride solution, and blood were given intravenously. A gastrointestinal series of roentgenograms disclosed a large filling defect within the distal duodenal cap and second portion of the duodenum. The stomach appeared to be elevated with indentation on the greater curvature; there was an almost complete obstruction present at the duodenojejunal juncture. The patient's condition remained unchanged for 3 days when he began to have tarry stools. Fresh whole blood (1,650 cc.) and fresh frozen plasma (800 cc.) were given over the next 3 days. Coincidental with the passage of tarry stools, the boy was able to take fluids by mouth, and the duodenal tube was removed. Within several days he was on a normal diet. It was postulated that the duodenal hematoma must have evacuated into the intestine.

Of 19 cases of acute obstruction of the small intestine secondary to hematoma in children which were collected from the literature, 13, in 10 boys and 3 girls, between the ages of 7 days and 15 years, have been reviewed. Eleven of these 13 children had a history of abdominal injury, as the authors' patients did. The most constant clinical features are abdominal pain, vomiting, and leukocytosis. Roentgenologic examination confirms the diagnosis. The condition can be treated without surgical intervention by gastric suction and intravenous administration of fluids. If surgery is performed because of erroneous diagnosis or election, evacuation of the hematoma without resection is the preferred treatment.

Exophthalmic Goiter in Children. A. B. Hayles, R. L. J. Kennedy, O. H. Beahrs and L. B. Woolner. J. Clin Endocrinol. 19:138-151 (Jan.) 1959 [Springfield, Ill.].

There has been considerable controversy as to whether children with exophthalmic goiter are best treated with antithyroid drugs or by subtotal thyroidectomy. During the period from 1908 through 1955 at the Mayo Clinic, 253 children, all less than 15 years of age, had thyroid disease diagnosed as exophthalmic goiter. It was hoped that observations over this 48-year period would add to the understanding of the course of exophthalmic goiter in children, and would help to appraise subtotal thyroidectomy as a method of treating it. There were 217 girls and 36 boys, a ratio of about 6:1. The disease in children does not appear to differ significantly from that in adults, although there is less tendency for children to have severe exophthalmos. Exophthalmos that occurs during childhood may persist for years after thyrotoxicosis has been relieved. Diabetes mellitus is observed more frequently among children with exophthalmic goiter than would be expected as a chance occurrence. Exophthalmic goiter during childhood, if adequately treated, does not alter adolescent development.

Subtotal thyroidectomy is a satisfactory and safe method of treating exophthalmic goiter in children. There were only 4 hospital deaths among 196 children treated in this way. No surgical death has occurred since 1933 among children treated by subtotal thyroidectomy. More extensive resection of the thyroid gland has not eliminated the recurrence of hyperthyroidism. Myxedema, although not considered a serious complication, occurs in a high percentage of patients treated by the extensive subtotal resection of the thyroid gland that is now carried out at the Mayo Clinic. Hypoparathyroidism, keloid formation in the operative scar, and injury to the recurrent laryngeal nerves rarely occurred in the patients of this series. The authors believe that a final evaluation of the best method of treating exophthalmic goiter in children must await an extensive experience with other methods of treatment.

Spontaneous Gangrene in Early Infancy. J. R. Vasquez, A. A. R. Mendilaharzu and J. E. Mosquera. Arch. argent. pediat. 29:152-163 (Sept.) 1958 (In Spanish) [Buenos Aires].

Five infants with spontaneous gangrene were observed in the Hospital de Niños in Buenos Aires between 1950 and 1956. The first, a newborn infant, was hospitalized in a critical condition with gangrene from obstetric trauma and septicemia. He did not respond to penicillin, streptomycin, and vasodilating drugs and died 10 hours after hospitalization. An autopsy showed deep and superficial thrombophlebitis of all veins in the region involved by gangrene. The other 4 patients were between the ages of 3 months and 1 year and, on hospitalization, were in a state of severe dehydration from septicemia, vomiting, and diarrhea. The treatment of these 4 patients consisted of intravenous injections of plasma, cortisone, penicillin, and streptomycin and subcutaneous injections of solutions to control dehydration. One infant with gangrene of the fingers of both hands and another with gluteal and facial gangrene responded well to the treatment; the areas of gangrene became limited, and the scars from necrotic tissue were eliminated, the patients being discharged one month after hospitalization.

The remaining 2 patients (the 4th and 5th of the series) were hospitalized in a very critical condition. The 4th patient had gangrene of the fingers of one hand, meningeal symptoms, and pneumonia. Besides the treatment given to all the patients, she was given intravenous injections of an acetylcholine preparation (Arterocolina), but death occurred 24 hours after hospitalization. No autopsy was granted. The 5th patient had symmetric gangrene of the hands and feet. Radial and tibial posterior pulses were absent. In addition to the treatment given to the other patients, this patient had anesthetization of the splanchnic nerves, and Novocain was used to anesthetize the stellate ganglion, but the child died 10 hours after hospitalization. An autopsy failed to show thrombosis or sclerosis of arteries and veins, but the cubital and radial arteries showed a fibrinoid degeneration. The author states that this case of symmetric spontaneous gangrene of the hands and feet of an infant is the first to be reported in the literature. It suggests an unknown predisposing factor, probably fibrinoid necrosis, which in association with other common causal factors determines this special type of gangrene in infants.

"Maple Syrup Urine Disease": An Inborn Error of the Metabolism of Valine, Leucine, and Isoleucine Associated with Gross Mental Deficiency. D. Y. Mackenzie and L. I. Woolf. Brit. M. J. 1:90-91 (Jan. 10) 1959 [London].

A girl, aged 4 months, with severe mental deficiency was admitted to the Hospital for Sick Children in Oxford. Her condition at birth appeared normal. When one week old she stopped sucking and had to be tube-fed. At 4 months she was noticed to be jerking her limbs and occasionally to become breathless and cyanosed. There was no control of head movements, although she occasionally attempted to follow a bright light with her eyes. A firm liver edge was palpable 1 to 2 fingerbreadths below the costal margin. Lumbar puncture produced a normal cerebrospinal fluid under normal pressure, but the electrocardiogram showed an abnormal record. The urine was examined to exclude phenylketonuria. On smelling a fresh specimen, the similarity to maple sirup was detected. On paper chromatography of the urine, valine, leucine, and isoleucine were found in large amounts. These amino acids were also present in the blood, cerebrospinal fluid, and saliva in great excess. Keto acids were present in the urine in large amounts, as were nonketo acids with the properties of alpha-hydroxy acids. The "maple sirup" smell is due mostly to the alpha-hydroxy acids, though modified by the keto acids. Paper chromatography of the urine for indole derivatives revealed an excessive excretion of indoleacetic and indolelactic acid. The blood true sugar concentration was only 60 mg. per 100 cc. after eating and 52 mg. per 100 cc. on fasting.

The authors suggest that this child has an inborn error of metabolism, and point out that Menkes, Hurst, and Craig in 1954 reported 4 cases, in one family, of severe progressive cerebral dysfunction, associated with the presence in the urine of an organic acid smelling like maple sirup. Also, Westall, Dancis, and Miller in 1957 reported one patient with "maple sirup urine disease," who had raised blood and urine concentrations of valine, leucine, and isoleucine and who in many respects resembled the patient reported here. "Maple sirup urine disease" is not a satisfactory name for the condition. Although one could use, for example, "leucic aciduria," there is no logical reason for picking one rather than another substance in the urine to provide a name for the disease. Since the inborn error of metabolism of the 3 amino acids may be associated with a block at the oxidative decarboxylation stage, "carboxylase deficiency disease" might eventually meet the need for a better term. Tryptophan metabolism is also interfered with, as in the case in patients with phenylketonuria. Differentiation of this condition from phenylketonuria needs special care.

OPHTHALMOLOGY

Presentation of an Unusual Case of Progressive Exophthalmos. R. W. Patterson Jr. and J. E. Campbell Jr. J. Tennessee M. A. 52:13-14 (Jan.) 1959 [Nashville].

The authors report on a 29-year-old woman who had been treated by an otolaryngologist for sore throat of several days' duration. Severe headache occurred, and pain and tearing of the left eye were followed by definite 3-to-4-mm. proptosis of the left eye, with marked edema and tenderness about the left orbit, for which the patient was hospitalized with a diagnosis of retrobulbar abscess. During the initial period of hospitalization large doses of antibiotics were administered, but the course of the exophthalmos rapidly increased in severity. The proptosis and chemosis became extreme. No evidence of thyroid dysfunction could be found. In an effort to halt the progression of the exophthalmos, corticotropin (ACTH) was given in association with desiccated thyroid. The emotional stability of the patient became uncontrollable, and prednisone in doses of 40 mg. daily was substituted for corticotropin. Within several days the proptosis and chemosis began to show definite improvement. On discharge the patient was receiving a daily dose of 30 mg. of prednisone,, and this was gradually reduced to 8 mg. daily. The proptosis disappeared completely 9 months after the initial attack and 2 months after complete withdrawal of the drug. The causation of the exophthalmos in this patient was unknown, but the condition responded dramatically to treatment with prednisone. Cases of progressive exophthalmos may occur in the absence of any demonstrable thyroid abnormality.

Cortical Blindness with Partial Recovery Following Acute Cerebral Anoxia from Cardiac Arrest. W. F. Hoyt. A. M. A. Arch. Ophth. 60:1061-1069 (Dec.) 1958 [Chicago].

The author reports on a 39-year-old woman with cortical blindness resulting from cardiac arrest leading to profound cerebral hypoxia. The patient had suffered multiple stab wounds in the right side of the chest, inflicted with an ice pick by a man with whom she had been living. On admission to hospital, pneumothorax was suspected and confirmed by a chest roentgenogram. During the performance of the x-ray examination the patient suddenly had acute respiratory distress and became unconscious. Within 2 minutes an emergency thoracotomy was performed, and manual massage of the heart was begun. Within 3 to 5 minutes normal heart beat and blood pressure were restored. The pneumothorax was controlled with catheters placed in both chest cavities. To combat the effects of acute cerebral hypoxia, the patient was placed in hypothermia within 2 hours after thoracotomy, and her body temperature was lowered to 88 F (31 C). She remained in deep coma; her pupils were dilated and fixed and did not respond to light. Hypothermia was maintained for 3 days and coma continued for 36 to 49 hours. Hypothermia was discontinued when the patient's pupils responded briskly to light. Within 12 hours she was able to talk readily, and her comprehension was good.

Nine days after the stabbing, the patient was moved to a general hospital ward through crowded corridors and onto elevators. It was reported that she was unable to see the people whose voices she heard around her. At this time neurological examination revealed that her reflexes and general body sensations were intact and that she had no cerebellar signs. However, she was unable to recognize a small hand light in any part of the visual field of either eye, and she could not perceive hand motions, although her pupillary reactions and optic fundi were entirely normal. At this time classical cortical blindness was recognized.

The case of this patient illustrates true cortical blindness as differentiated from blindness arising from more extensive lesions, such as are frequently described under the eponym "bilateral homonymous hemianopsia." The author believes that there are 2 main reasons why the patient had cortical blindness and failed to show signs indicating more extensive cortical damage. These factors are hypothermia and transtentorial shift. Hypoxia influences particularly laminas 3 and 4 of the cortex, and the visual cortex is particularly susceptible (also the motor cortex, basal ganglions, and cerebellum). Profound involvement of the visual cortex, without evidence of involvement of other cortical areas in this patient, suggests that hypothermia may have avoided some of the cerebral damage which characterizes such cases. However, particular vulnerability of the posterior pole of the brain to acute anoxia and, in addition, some degree of transtentorial herniation occurring as a result of swelling (with resultant embarrassment of the blood supply to the visual cortex) may well explain cortical blindness in this patient.

INDUSTRIAL MEDICINE

Clinical Evaluation of Methocarbamol (Robaxin) in an Industrial Facility. C. S. Plumb. Journal-Lancet 78:531-532 (Dec.) 1958 [Minneapolis].

Skeletal muscle spasm is a complaint frequently encountered in industrial medical practice. The industrial physician must attempt to provide sufficient relief, so that the worker can return to his job, but he also must be sure that the worker can perform his duties in a safe manner, for nothing would be gained if side-effects were induced that might render the worker vulnerable to accident or injury. Mephenesin and then zoxazolamine were popular for some time as muscle relaxants, but had shortcomings. This paper is concerned chiefly with methocarbamol (Robaxin), the latest addition in the field of muscle relaxants which has a more extended activity than mephenesin.

Observations are reported on 60 industrial workers who were treated with methocarbamol. These patients encompassed a good cross section of 2,500 workers of a chemical and paper manufacturing industry. Care was taken to include in this study only workers who, on their initial examination, were considered to have uncomplicated skeletal muscle spasm. The minimal dose of methocarbamol necessary for a satisfactory response was found to be 1 Gm. (2 tablets) every 4 hours; smaller doses did not produce the desired results. Fifty-five of the 60 workers could return to full or light duty. The author concludes that methocarbamol reduces muscle spasm without producing side-effects, and that it is a safe drug, which the industrial physician may use with confidence.

Mortality Due to Coronary Disease Analyzed by Broad Occupational Groups. J. M. Mortensen, T. T. Stevenson and L. H. Whitney. A. M. A. Arch. Indust. Health 19:1-4 (Jan.) 1959 [Chicago].

The question whether executive and managerial personal are more likely to die of a coronary heart disease than laborers was the motive for this study based on the mortality rate among male employees of the U. S. Bell Telephone Company. This investigation was carried out over a 5-year period beginning in 1951 and extending through 1955. Deaths were classified according to the International List of Causes of Deaths. A comparison of the death rates of coronary causes and of all causes showed a sharp rise in the proportion of coronary deaths in persons ranging in age from 26 to 40 years. At the age of 40 years the ratio of deaths due to coronary disease and the total deaths was almost the same, staying within the range of 30 to 40% through the age of 60 years. A slight decline appeared at the later age. Active employees, ranging in age from 40 to 64 years, were used for comparison among the different occupation groups. This age group made up more than 375,000 life years of exposure in the 5-year period, and among these workers 1,082 deaths due to coronary causes occurred. In order to make a comparison among the occupations, the employees were classified into groups according to their type of work and the responsibility involved.

The ratio of actual to expected deaths in the group of white-collar workers was 106%, with a probable deviation of ± 3; there is a 50% chance that the true ratio for this group would be between 103 and 109%. A similar range for the group of laborers was from 93 to 99%. Even though the death rate of coronary causes appeared to be higher in the group of white-collar workers, there was no consistency within the groups. The subdivisions of the group of managers, which included officials, supervisors of staff, and foremen, could be classified as pertaining to top, middle, and lower management. The top executives not only showed the lowest level of mortality of the group of managers, but also of the entire group of employees. The high mortality rate of the clerical group was to some extent caused by a transfer of physically impaired craftsmen into this group.

Summarizing the results of this study, it is evident that among male employees of the Bell System there is no substantial difference between the mortality rate due to coronary disease of the top executives and that of craftsmen and laborers, but there is a marked difference between the mortality rate of top executives and that of middle managerial personnel. This fact cannot be explained by these data. The popular notion that top executive positions are associated with a high death rate caused by coronary disease may be attributed to the great publicity connected with these deaths rather than to statistical facts.

THERAPEUTICS

Mechanism of Action of Pyretotherapy in Neurosyphilis: Possibilities of Use in Leprosy. M. B. Moreira. Rev. brasil. med. **15**:624-628 (Sept.) 1958 (in Portuguese) [Rio de Janeiro].

General paresis and tabes dorsalis are controlled by pyretotherapy by a dual mechanism of effects of intermittent marked changes of temperature on Treponema pallidum and a reaction of the reticuloendothelial system with an increased production of phagocytes. In neurosyphilis, pyretotherapy kills T. pallidum or makes it more vulnerable to the effects of antisyphilitic drugs and more amenable to phagocytosis, which is carried out by the large mononuclear cells, the lymphocytes, and the microglia. Neurosyphilis and leprosy are nonfebrile diseases whose causal organisms are susceptible to induced pyretotherapy. Pyretotherapy in leprosy renders Mycobacterium leprae more vulnerable to the effects of the sulfones and more amenable to phagocytosis. A large number of patients with leprosy in the San Roque Colony in Rio de Janeiro have been treated with sulfone compounds after pyretotherapy. This article is a preliminary note, aimed at inciting interest in the possibilities of pyretotherapy in leprosy. The results up to now have been very promising.

The Protein-Sparing Effect of Androgenic Hormones After Gastrectomy. R. G. A. van Wayjen, J. Groen and A. F. Willebrands. Nederl. tijdschr. geneesk. **102**:2413-2422 (Dec. 6) 1958 (In Dutch) [Amsterdam].

The utilization of proteins was investigated by means of balance studies in 31 patients who had been subjected to gastrectomy. The amount of food eaten was carefully weighed, and, in order to determine the utilization of proteins by the body, the nitrogen content of the urine and feces and the fat content of the feces were ascertained. The balance studies required from 10 to 45 days. A total of 41 balance studies were carried out, some patients being subjected to more than one. Thirteen of the patients were treated with androgenic hormones, and 18 were not. The utilization of proteins improved in all except one of the male patients treated with androgenic hormones in the form of testosterone propionate. A lower dose of testosterone propionate combined with estrogens improved the nitrogen balance in a female patient.

Comparison of the calorie intakes and of the body weights of the patients while they were in the hospital revealed that those receiving hormone treatment consumed an average of 2,355 calories a day and gained an average of 3.9 kg. (8½ lb.) in weight over a period of 30 days; the respective figures for the 18 patients not receiving hormone therapy were 2,740 calories and 1.4 kg. (3 lb.). Thus, the treatment with androgenic hormones was accompanied by a greater weight increase. Furthermore, the increase in weight continued when, after discharge from the hospital, the patients were given maintenance doses of testosterone phenyl propionate. The androgenic hormone therapy caused no unpleasant side-effects. The authors feel that androgenic hormone therapy can be recommended for patients whose nutritional status is impaired as the result of total or partial gastric resection.

Chlorothiazide (Chlotride) as Part in Treatment of High Blood Pressure. H. S. Mathisen and D. Jensen. Tidsskr. norske lægefor. **78**:1230-1231 (Dec. 15) 1958 (In Norwegian) [Oslo].

Sixty patients (27 men and 33 women) with hypertension were treated with chlorothiazide for an average of 6.2 months. The agent was administered by mouth in 0.5 Gm. tablets, and seldom more than one tablet was given daily. Often the dose was reduced to one-half tablet daily, given after breakfast and with 1 or 2 days' interlude during the week on long-term treatment. Except in one case, chlorothiazide was combined with one or several other hypotensive medicaments with which the patient had been treated for some time. In the combined hypotensive treatment, the dosage of the other hypotensive substances was unchanged, except in the case of ganglion-blocking agents whose doses were usually cut in half. Chlorothiazide taken by mouth in doses of 0.25 to 0.5 Gm. not only has a diuretic effect but also reduces the blood pressure in hypertensive patients. In these doses chlorothiazide increases the effect of other hypotensive agents (hydralazine, rauwolfia, protoveratrine, and ganglion-blocking agents). Patients who have undergone sympathectomy are sensitive to chlorothiazide treatment. The agent is well borne, with minimal side-effects, and is regarded as valuable in the medicinal treatment of high blood pressure.

Antibacterial Effect of Ristocetin. A. Farulla, A. Cassano, L. Nuzzolo and G. Giordano. Riforma med. **72**:1353-1355 (Nov. 29) 1958 (In Italian) [Naples].

A study in vitro on the antibacterial effect of ristocetin is reported on. The antibiotic used in the study contained component A and component B of ristocetin in a proportion of 70 and 30% respectively. The minimum concentration of ristocetin necessary to inhibit the growth of Micrococcus (Staphylococcus) pyogenes var. aureus was 4.5 mcg. per milliliter; in some cases, though, it was 9.4 mcg. per milliliter. The minimum inhibitory concentration values obtained in tests with hemolytic streptococci and streptococci of the viridans group ranged from 0.3 to 1.2 mcg. per milliliter. Marked sensitivity was noticed in tests with Streptococcus faecalis and Diplococcus pneumoniae. Ristocetin had no antibacterial effect on gram-negative bacteria, but all gram-positive bacteria from recently isolated strains were sensitive to the drug. Fifty strains of M. aureus, 10 of hemolytic streptococci, 10 of Str. faecalis, and 10 of D. pneumoniae showed 100% sensitivity to ristocetin, and no natural resistance was noticed. All the strains of hemolytic streptococci, Str. faecalis, and D. pneumoniae were 100% sensitive to such other antibiotics as penicillin and tetracycline, while M. aureus showed a 42% sensitivity to penicillin and a 96% sensitivity to tetracycline.

PATHOLOGY

Pleural Biopsy in the Diagnosis of Pleural Effusion: A Report of 200 Cases. P. Mestitz, M. J. Purves and A. C. Pollard. Lancet 2:1349-1353 (Dec. 27) 1958 [London].

The authors performed 228 punch biopsies of the parietal pleura, using the Harefield needle, on 200 patients, between the ages of 3 and 85 years, most of whom had an effusion at the time of the investigation. One hundred seventy-four patients had one biopsy, 24 patients had two, and 2 patients had three. Biopsy established the diagnosis by determining the cause of the effusion in 80% of the patients with tuberculous effusions and in 60% of those with malignant effusions. Pleural punch biopsy proved to be by far the most reliable diagnostic technique in patients in whom tuberculosis was suspected. Only one of the diagnoses made with the aid of the 228 biopsies proved to be wrong. Pleural punch biopsy may be the only way of making a definite diagnosis during life. Trivial complications consisted of subcutaneous hematoma in one patient and a small pneumothorax in another patient. Pleural punch biopsy is a simple and safe method which should be part of the initial investigation of every patient with a pleural effusion of uncertain causation.

Ossifying Bronchial Adenoma. C. P. Thomas and A. D. Morgan. Thorax 13:286-293 (Dec.) 1958 [London].

It is generally conceded that bronchial adenoma is a benign epithelial tumor of mucous glands, with a cylindromatous variant of low-grade malignancy, but the "mixed tumor" theory still has adherents. The occasional presence of bone in the growth is usually attributed to metaplasia of the stroma. The frequency with which ossification occurs in bronchial adenomas is difficult to assess. Between 1939 and 1958, 63 cases of bronchial adenoma were treated by resection by one of the authors. Widespread ossification of the type dealt with by the authors was mentioned by the pathologist in only 3 cases, which are described in this paper. The authors conclude that bone formation in tumors is due to a metaplasia of the stroma brought about by multiple factors. Its relative frequency in bronchial adenomas is due in part to slow growth, but principally to the presence of cartilage in or near the tumor. The cartilage undergoes necrosis and calcification and affords a convenient medium for ossification. Where distant metastases of malignant epithelial tumors are ossified, the metaplasia is probably due to a chemical influence exerted by the tumor cells themselves.

The Effect of Hypercalcemia Induced by Calciferol upon Renal Concentrating Ability. F. H. Epstein, M. J. Rivera and F. A. Carone. J. Clin. Invest. 37:1702-1709 (Dec.) 1958 [New York].

Polyuria and loss of renal concentrating ability have frequently been observed in patients with hypercalcemia. It has not been clear whether the capacity of the kidneys to concentrate urine is selectively impaired by hypercalcemia or whether it is depressed, together with many other renal functions, as a result of injury to and encroachment upon active renal parenchyma. In the experiments described, the effects of hypercalcemia on renal function and morphology were studied in rats given large doses of calciferol (vitamin D_2) for several days. Hypercalcemia was induced in rats by 4 daily injections of 200,000 to 400,000 units of calciferol. Renal concentrating ability was markedly impaired, although there was little or no change in blood urea, urea clearance, or the excretion of phenolsulfonphthalein. Morphologic changes in the kidneys were sparse and consisted chiefly of lesions involving the collecting ducts in the outer medulla. It is suggested that similar alterations in renal structure and function may be responsible for the polyuria and hyposthenuria observed in a variety of clinical states associated with hypercalcemia or nephrocalcinosis.

RADIOLOGY

The Advantages and Limitations of Cobalt 60 Hectocurie Teletherapy. N. Simon and S. M. Silverstone. Am. J. Roentgenol. 81:38-42 (Jan.) 1959 [Springfield, Ill.].

The authors feel that occasional bursts of enthusiasm by the lay press distort and exaggerate the benefits derived from radio cobalt (Co^{60}) teletherapy, but the radiotherapist realizes that the true value lies somewhere between the exaggeration of the lay press and the iconoclasm of the over-conservative radiologist. The beneficial features of Co^{60} teletherapy include: (1) skin sparing; (2) increased depth dose; (3) lessened bone absorption; (4) decreased side-scatter; and (5) simplicity of operation. Skin sparing of the Co^{60} beam is by far its most advantageous characteristic. It allows high dosage through single portals, and sometimes this skin sparing provides access with radiation to lesions which are not usually considered treatable. For example, carcinoma of the rectum, either the postoperative recurrence or the locally unresectable lesion in the hollow of the sacrum, is difficult to treat unless the skin over the sacrum can be spared.

Although increased survival may be too much to expect, palliation and control of bleeding are more often achieved with Co^{60} teletherapy than with irradiation in the "conventional" range. The lessened bone absorption with Co^{60} teletherapy increases the dose to tissues beneath bone, such as brain and pelvic organs, and it is also possible that radionecrosis of bone may be lessened. The decreased side-scatter of the Co^{60} beam is presumed to account for lessened radiation sickness. The experience of these authors in the treatment of 600 patients with a Co^{60} hectocurie unit in the past 3 years bears out this presumption. Finally, a Co^{60} hectocurie apparatus is far simpler to operate than a 200-kv. or supervoltage roentgen-ray machine.

The authors discuss the following disadvantages of Co^{60} hectocurie therapy in comparison with 200-kv. roentgenotherapy: (1) unsuitability for intraoral (and intravaginal) therapy; (2) unsuitability for treatment of skin cancer; (3) reduced usefulness of the large fields; (4) too much penumbra at long-source skin distances; and (5) requirement of radiation protection of operating personnel. The use of electron filters to help in the design of cones, particularly for treatments at short-source skin distances with the hectocurie units, is discussed. There are two advantages to the use of short-source skin distances: (1) increased output and (2) rapid dose fall-off. These advantages can be obtained, while still retaining the skin-sparing feature of Co^{60} teletherapy, by closing the end of the cone with a thin sheet of brass.

An important lesion deserving special comment in relation to Co^{60} hectocurie teletherapy is carcinoma of the larynx. Early results in 30 patients indicate as favorable a response as the best obtained with 200-kv. roentgenotherapy. In addition, the patient has no skin discomfort, and after a few months the epilation is the only identifying characteristic of the skin treated. If laryngectomy is indicated for persistence or recurrence of the lesion after Co^{60} treatment, healing of the operative wound will not be seriously hampered. The relatively low morbidity, the retention of voice, and the comparatively satisfactory "cure" rate render Co^{60} hectocurie teletherapy the treatment of choice in lesions confined to the larynx.

Zinc-65 in Foods and People. R. W. Perkins and J. M. Nielsen. Science 129:94-95 (Jan. 9) 1959 [Washington, D. C.].

Trace amounts of radiozinc (Zn^{65}) are disposed in the Columbia River via Hanford reactor effluent water. The subsequent utilization of river water for irrigation permits concentration of this radioisotope in farm produce and its eventual deposition in man. The authors report on measurements of Zn^{65} in irrigation water, in farm produce, and in individuals utilizing these materials. The farm-produce and animal samples considered here were obtained from an irrigation project about 30 miles downstream from the Hanford reactors. By means of gamma-ray spectrometric techniques, measurable amounts of Zn^{65} were found in all the farm produce sampled from this location. The Zn^{65} concentrations found in milk, beef, and various vegetables from this land are shown in a table. The fact that the pasture grass contained a relatively high Zn^{65} concentration, as compared with the vegetables, is probably related to both the manner and the amount of irrigation, as well as to the fact that some difference in uptake exists between leaf and fruit portion of plants. The pasture grass was irrigated almost continuously, while the vegetables were irrigated only a few times during their growing season. In addition, the Zn^{65} may enter the grass by foliate absorption during irrigation as well as through the soil.

The relatively high Zn^{65} concentration in milk, as compared with that in pasture grass, indicated that a large amount of Zn^{65} is taken from the feed into the blood stream of the cow and translocated into the milk. The low Zn^{65} concentration found in beef samples may be explained by the fact that the animal in question was slaughtered in late winter and had been fed on essentially Zn^{65}-free foodstuffs for 3 or 4 months prior to that time. The Zn^{65} concentration in flesh, fat, and bone samples of another beef animal, which had spent its entire life in the same location, was about twice that in the first animal in the previous year. It was also observed that hair, liver, and bone concentrate zinc to a greater extent than other organs.

The gamma-ray spectrum of an individual who consumed approximately 0.1 and 0.7 kg, respectively, of meat and milk per day from the source mentioned is shown in a figure. Measurements were made in 12 other persons whose diet did not include food from the irrigation project but did, in some cases, include drinking water from the Columbia River. The presence of Zn^{65} in the amounts observed in no way constituted a hazard. Even the amount in the individual whose diet included meat, milk, and drinking water from the project was less than 0.01% of the total permissible body burden for this isotope. Also, even the highest Zn^{65} value in pasture grass was less than 5% of the maximum permissible concentration for human foods.

Irradiation of the Entire Body and Marrow Transplantation: *Some Observations and Comments.* E. D. Thomas, H. L. Lochte Jr. and J. W. Ferrebee. Blood 14:1-23 (Jan.) 1959 [New York].

The authors mention previous experimental and clinical studies on whether infusion of normal bone marrow will induce recovery after exposure to irradiation that otherwise would prove fatal. They point out that there are dissimilarities between man and lower animals that make translation of the experimental data difficult. In this communication they present further clinical experience with whole-body irradiation and marrow transplantation by presenting the histories of 5 patients with acute leukemia who received total-body irradiation and intravenous infusion of normal marrow. An 8-month follow-up on a previously reported patient with chronic leukemia is included, and a review of the case of a person receiving nitrogen mustard and marrow is presented. Of several patients reported in this and in a previous communication, only 2 may be said to have obtained significant clinical benefit.

Possible reasons for this low incidence of improvement are suggested, and the difficulties involved in total-body irradiation and marrow replacement in man are discussed. The authors mention the difficulties in cell division resulting from ionizing radiation and the involved cessation of *production of the circulating formed elements:* platelets, leukocytes, and erythrocytes, which, in turn, is followed by bleeding and infection. Other problems discussed are possible immunological reactions to marrow transplantations, the number of cells required and obtainable from fetuses and from cadavers, the use of spleen, the time after irradiation at which marrow should be administered, and the technical difficulties involved in total-body irradiation.

Carotid Angiography in the Localization of Supratentorial Neoplasms and Hamartomata. P. F. J. New. Radiology 72:35-41 (Jan.) 1959 [Syracuse, N. Y.].

In an attempt at assessment of the value of carotid angiography in the localization and diagnosis of supratentorial neoplasms and hamartomas, the author reports on 131 supratentorial neoplasms and arteriovenous malformations studied and verified between 1952 and 1957. Of the 131 lesions, 130 were examined by carotid angiography, and in 35 of these pneumography (encephalography and/or ventriculography) was employed in addition to angiography. Only one lesion was studied by encephalography alone. Of the 131 lesions, 88 (48.4%) were gliomas, 14 were meningiomas, 11 were metastases, and 18 were arteriovenous malformations. The results of these studies showed that cerebral angiography may be safer and less disturbing to the patient than pneumography. It is *less time-consuming* than a properly conducted pneumographic study.

It is postulated that most of the supratentorial space-occupying lesions are best examined first by carotid angiography. This method alone will frequently provide a pathological diagnosis in addition to a satisfactory localization, judged by the presently accepted criteria of accuracy. A high *proportion of avascular space-occupying lesions* will be accurately localized; most of the exceptions will be tumors limited to the occipital or parietal lobes, to the deep central portions of the hemispheres, or very early, small lesions. In a moderate number of cases additional pneumography, usually encephalography, will be required to provide additional information regarding the site and extent of the lesion. Unfortunately very extensive infiltrating gliomas can occasionally exist with no definite angiographic or pneumographic abnormality. A negative angiogram in the presence of reasonable clinical suspicion of a neoplasm should lead to pneumography, either within a few days, if the index of suspicion is relatively high, or within a few weeks, if suspicion is not so great initially but symptoms and signs are progressive. Suspected midline basal neoplasms are best investigated in the first instance by pneumography unless a meningioma or other vascular mass is suspected. The present aim is to use very rapid serial angiography to provide more detail of the circulation of the tumor and to employ angiography combined with pneumography in more and more cases, as the presently accepted criteria of accuracy of localization are not felt to be satisfactory.

BIOCHEMISTRY

The Immediate Effect of Hypophysectomy and Section of the Pituitary Stalk on the Urinary Steroid Excretion in Man. B. Hökfelt, R. Luft, D. Ikkos and others. Acta endocrinol. 30:29-36 (Jan.) 1959 (In English) [Copenhagen].

The urinary excretion of steroids, including aldosterone, was studied immediately after operation in 2 men who had been subjected to hypophysectomy because of metastasis of malignant melanoma and in a woman in whom the pituitary stalk had been sectioned because of carcinoma of the thyroid with metastases. For evaluation of the steroid hormone production the 24-hour urinary output was collected without preservative, and stored in the refrigerator. Hypophysectomy was found to result in the disappearance of nonconjugated cortisol and cortisone, as well as of the corresponding tetrahydro derivatives. In agreement with this, there was a rapid and marked decrease in total 17-ketogenic steroids. Sectioning of the pituitary stalk was found to produce an increase in the urinary output of these metabolites. Changes parallel to those in 17-ketogenic steroids were observed in the 17-ketosteroids. An increase in the urinary excretion of aldosterone was found in all 3 patients.

The Biology of Metacorticoid Hypertension. F. M. Sturtevant. Ann. Int. Med. 49:1281-1293 (Dec.) 1958 [Lancaster, Pa.].

The search for effective treatment of essential hypertension has led to the laboratory exploration of many contributing factors, and 4 major types of experimental hypertension: neurogenic, renal, renoprival, and hormonal have been chiefly investigated. Green in 1953 and 1954, while reviewing the similarities and differences among human and experimental hypertensions, concluded that essential hypertension in human subjects is simulated most closely by the post-DOCA (desoxycorticosterone acetate) or metacorticoid syndrome. The author reviews all available information on this syndrome, pointing out that metacorticoid hypertension is a self-sustaining disease that is no longer dependent upon a continuing overdosage with DOCA and dietary sodium. The term "metacorticoid" in place of "post-DOCA" or "self-sustaining" was suggested by Selye, who likened this condition to the "metahypophysial" and "metathyroid" diabetic states described by Houssay.

Metacorticoid hypertension is produced in this author's laboratory by the subcutaneous implantation in 75-Gm. male rats of an extruded pellet containing a 2:1:1 mixture of DOCA, Carbowax 4000, and Flexowax C Light. Each pellet weighs 40 mg. Immediately after implantation, the rats are offered only 0.86% sodium chloride solution as drinking fluid, and are kept for a 3-month waiting period, after which they are considered to be "metacorticoid." The pellet remnants at this time contain only 0.2 to 0.3% of the original amount of DOCA.

The author concludes that metacorticoid hypertension is a self-sustaining disease in rats that is produced by temporary overdosage with DOCA and sodium. It may be characterized by an exaggerated urinary excretion of sodium and water, which is related to the duration of the disease, the sodium and water intake, and the blood pressure level. The urinary sodium/potassium ratio is elevated. When the rats are offered only isotonic sodium chloride solution or water to drink, there is a relative polydipsia; when they are offered a free choice between the two, a relative aversion to the sodium chloride solution is exhibited. The life expectancy of the metacorticoid rat is greatly reduced, although individual rats may live a year or more after DOCA implantation. The elevated blood pressure, cardiovascular reactivity, vascular lesions, disturbances in salt and water metabolism, and decreased life expectancy appear, to some extent, to be independent of each other. The maintenance of the disease is dependent upon the pituitary, the thyroid, and the kidney. Clinically active drugs cause transitory decreases of blood pressure in metacorticoid rats, although seemingly huge doses are often required.

Ionised, Protein-Bound, and Complexed Calcium in the Plasma in Primary Hyperparathyroidism. H. M. Lloyd and G. A. Rose. Lancet 2:1258-1261 (Dec. 13) 1958 [London].

Calcium is present in plasma in the ionized, complexed, and protein-bound states. Although the 3 fractions are believed to be in equilibrium with one another, the level of the ionized calcium is regarded as the one most immediately related to the activity of the parathyroids. The authors report the results of measurement of the plasma calcium fraction in 17 patients with primary hyperparathyroidism. They are especially concerned to note the value of these measurements for the diagnosis of the disorder. In 16 of the 17 patients the condition was shown to be due to a single chief-cell adenoma, which was removed. In the remaining patient explorations of the neck and mediastinum were negative, but the diagnosis was not in doubt. The level of ionized calcium in the plasma was raised before operation in every patient, except one who was probably in temporary remission. After removal of the adenoma the level of ionized calcium always fell to normal or below normal; this fall was proportionately greater than the fall in the protein-bound fraction. It was inferred that the parathyroid hormone reduces the ability of the plasma proteins to bind calcium.

As a result of investigations on the patients, it was considered desirable to investigate the effect of administering parathyroid hormone to a healthy volunteer. Accordingly, the plasma calcium fractions were measured before and after 5 intramuscular injections of 400 U.S.P. units of Parathormone given at intervals of approximately 12 hours. Observations on this volunteer corroborated that parathyroid hormone reduces the ability of plasma proteins to bind calcium. It has been observed that it is possible for patients with normal total plasma calcium and with normal plasma proteins and pH to have a high ionized fraction. In such cases measurement of the ionized calcium in the plasma is a most valuable diagnostic aid. This measurement is also a valuable screening test for patients with "idiopathic hypercalciuria" in order to exclude primary hyperparathyroidism. If the level of ionized calcium in the plasma is raised, the hypercalciuria is not "idiopathic."

PUBLIC HEALTH

Second Chest X-Ray Survey of the Population of Amsterdam. A. Kalthofen, B. van Vliet and J. van der Zee. Acta. tuberc. scandinav. 36:141-151 (no. 2-3) 1958 (In English) [Copenhagen].

A second chest x-ray survey was carried out on the population of Amsterdam between June, 1954, and August, 1957. Only persons over 14 years of age were included. The results of this second survey were compared with those of the first one carried out between April, 1951, and May, 1954. Among the 400,959 persons examined, 179 were found to have no previously detected pulmonary tuberculosis. In the first survey in which 411,111 inhabitants were examined, 379 persons with formerly unknown active pulmonary tuberculosis were detected. This was practically a 100% decrease; the number detected was smaller by 200, whereas the number of persons examined was only slightly smaller. Although the number of females examined was 12% larger than the number of males, the incidence of tuberculosis among females was lower by 58%. The maximal number of cases of tuberculosis was found among males of the age group 40 to 49, while the minimal number was found among females in the age group 50 to 59.

Pulmonary tumors were demonstrated in 185 persons during the second survey, that is, tumors were more numerous than tuberculosis. The 185 tumors included 19 that were benign, 31 that were suspected of possible malignancy, and 135 that were definitely malignant tumors. There were 96 patients in whom bronchial carcinoma had been clinically demonstrated; 24 of these had been operated on with good early result. In the first survey 176 pulmonary tumors (including 135 malignant ones) had been demonstrated.

A Rapid Test for Detecting Staphylococcus aureus in Food. E. Wilson, M. J. Foter and K. H. Lewis. Appl. Microbiol. 7:22-26 (Jan.) 1959 [Baltimore].

Coagulase-positive staphylococci are responsible for approximately 75% of the food-borne illnesses of established etiology that have been reported in the United States during recent years. To determine the relation of a suspected food to staphylococcic food poisoning, the presence of enterotoxin should be demonstrated, but the methods available for this purpose are cumbersome. In lieu of demonstrating enterotoxin, a rapid method has been developed for detecting the bacteria that are known to produce enterotoxin, that is, the coagulase-positive staphylococci. The method allows detection of Staphylococcus pyogenes var. aureus in food within a 7-to-9-hour period. A selective culture technique in brain heart mannitol salt broth has been combined with the growth-accelerating effect of agitation in air during incubation. After the incubation with shaking of 4 to 6 hours at 35 C, the broth culture is used for a gram-stained preparation and for the coagulase test. Modifications of the method are proposed for use when circumstances preclude completion of the entire procedure in a single working day.

Studies were performed with experimentally contaminated ham, custard, creamed chicken, and milk. When Staph. aureus was present in these foods in pure culture, it was detected in 7 to 9 hours at levels ranging from 2,200 to 48,200 per gram, depending upon the food examined; whereas in the presence of 4 million to 15 million aerobic sporeformers per gram, staphylococci were detected at levels ranging from 17,000 to 43,500 in custard, and 19,000 to 167,500 in ham. In the presence of enterococci, salmonellae, and aerobic sporeformers totaling 105 million per gram, staphylococci were detected at the level of 235,000 per gram in a 9-hour total test period. These data indicate that the rapid test permits detection of Staph. aureus well below the level cited in the literature as the threshold for the production of sufficient enterotoxin to induce symptoms in man. Principal advantages of this new test are its speed, simplicity, and the ready availability and low cost of the equipment required. Speed of the test is important in relation to epidemiologic investigations of food poisoning outbreaks, and the relative simplicity of the procedure makes it a feasible quality control test for commercially prepared nonsterile foods. The test has not as yet been used for clinical materials.

The Age Factor in Postvaccinal Encephalitis. K. Berger and F. Puntigam. München. med. Wchnschr. 100:2042-2043 (Dec. 26) 1958 (In German) [Munich, Germany].

Investigations were made in Austria on the incidence of postvaccinal encephalitis in relation to the age of the child at the first vaccination. It was found that this complication of vaccination not only shows a general increase among children who are vaccinated for the first time after the age of 3 years, in comparison with children who are vaccinated before they are 3, but the incidence rises further in successive age groups. The grouping according to age of 32 children in whom postvaccinal encephalitis developed during 1948-1953 and the grouping of the 69,706 vaccinations according to the ages of the children showed that, whereas in children vaccinated for the first time under 3 years of age 1 case of postvaccinal encephalitis developed in 9,958 children, for the age group of 4 to 5 years it was 1 case in 1,628, for the age group of 6 to 10 years it was 1 in 430, and for the age group of 11 to 14 years it was 1 in 85.

BOOK REVIEWS

New and Nonofficial Drugs: Containing Descriptions of Therapeutic, Prophylactic and Diagnostic Agents Evaluated by the Council on Drugs of the American Medical Association, 1959. Annual publication issued under direction and supervision of Council. Cloth. $3.35. Pp. 687. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada, 1959.

This book contains monographs on drugs which have been evaluated on the basis of available scientific data by consultants and members of the A. M. A. Council on Drugs. It begins with a statement of the principles governing the evaluation of the drugs which are described. The 1959 edition includes new Council monographs that have appeared in The Journal since the 1958 edition. Monographs on drugs which either have been included in the book for 20 years or are no longer commercially available have been deleted. The current edition contains approximately 500 monographs, of which 42 are new. A generic listing of available preparations and their strengths and sizes is given with each monograph. Trade names are listed at the end of each monograph and also in the index. Among the important new monographs are those for anileridine hydrochloride, dextro propoxyphene hydrochloride, iproniazid phosphate, oleandomycin phosphate, prochlorperazine, and ristocetin. In view of its admirable coverage of newer drugs, whether or not their usefulness has been established, all physicians and students of medicine should consider the purchase of this annual publication as a guide to drug therapy.

Television in Science and Iudustry. By V. K. Zworykin, E.E., Ph.D., D.Sc., E. G. Ramberg, Ph.D., and L. E. Flory, B.S. Cloth. $10. Pp. 300, with illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W. C. 2, England, 1958.

The authors explore the function of closed-circuit or industrial television and describe the tools which have been developed to realize it. A brief historical introduction in the first chapter covers the various attempts to televise in the prescientific era, developments during the era of speculation, and final emergence into the mechanical and electronic era. In chapter 2 the principal applications of television in industry, research, medicine, education, commerce, military affairs, and home and farm work are outlined. In chapter 3 the equipment which has been developed for closed-circuit television is described in detail, including the design and circuitry of the more conventional camera equipment, the miniaturization made possible by the transistors and 0.5-in. vidicons, the operation of color and stereo-television apparatus, and the television microscope.

In chapter 4 the status of closed-circuit television in 1957 is reviewed and examples are cited from actual practice in sufficient detail to enable the reader to judge the situations known to him in which closed-circuit television could be most effective, what equipment would be needed, and how it should be used. Complete references are given to the technical literature. In chapter 5 an attempt is made to forecast the future development of closed-circuit television, with a comparison of performance limits of vidicon and flying-spot television microscopes in the ultraviolet given as an appendix.

The reader of this book should receive an excellent basic education covering the birth, development, and growth of television. He should also become familiar with the many and varied uses of this versatile medium as it has been put to work in science and industry. The section on microscopy is especially detailed and contains valuable reference sources. The discussion of permanent and portable television apparatus as used in medicine is also quite complete for the period covered. Unfortunately, the speed in development and refinement of television apparatus in the past two years somewhat dates this book, but for those who are planning to enter the field of television it should serve as an excellent foundation. This book will be of primary interest to those who would like to familiarize themselves with the technical aspects of television.

Diseases of Children in the Subtropics and Tropics. By H. C. Trowell, O.B.E., M.D., F.R.C.P., Senior Specialist Physician, Pædiatric Unit, Mulago Hospital and Makerere College, University College of East Africa, Kampala, Uganda, and D. B. Jelliffe, M.D., M.R.C.P., D.C.H., Visiting Professor of Tropical Medicine, Tulane University, New Orleans. Cloth. $18.50. Pp. 919, with illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; Edward Arnold (Publishers) Ltd., 41-43 Maddox St., London, W. 1, England, 1958.

Most of the world's children are born and live in the subtropics and tropics. One would suppose that special textbooks dealing with the problems of these children would be available, but such is not the case. Most of those who are concerned with pediatrics in tropical areas have either been trained in the West or have studied textbooks written from the standpoint of Western medicine. The authors have prepared this volume, with the

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

assistance of about 70 contributors from all over the world, to meet an obvious need. Some of the communities in which these contributors work are Madras, India; London; Sydney, Australia; Uganda; Lagos, Nigeria; Manus, New Guinea; Buenos Aires; Colombo, Ceylon; Paris; Singapore; Bogotà, Colombia; Calcutta; Dakar, South Africa; Jamaica; Kenya; New Orleans; and Washington, D. C.

This book covers the broad field of diseases of children, but it does not attempt to be another standard textbook of pediatrics. Those maladies which are cosmopolitan, such as the infectious diseases of childhood and the commoner disorders of the respiratory and nervous systems, are presented briefly, and attention is called to unusual characteristics which may be due to the tropical environment. Numerous conditions which appear almost exclusively in the tropics and which a pediatrician in the temperate zones would rarely if ever see are described in detail. Among these are kwashiorkor, tropical eosinophilia, paragonimiasis, cholera, Indian childhood cirrhosis, veno-occlusive disease of Jamaica, maduromycosis, yaws, pinta, leprosy, African and Brazilian trypanosomiasis, visceral leishmaniasis, schistosomiasis, loiasis, dracontiasis, and vomiting sickness of Jamaica.

Much space is devoted to such factors that tend to alter or aggravate disease processes as poverty, illiteracy, ignorance, overwork, local superstition, heat, humidity, and malnutrition. These forces are met to some extent in the temperate zone, but the violence of their impact on the health of children cannot be appreciated until one reads of their influences in the tropics. The material is presented in interesting, readable form. Since most of the contributors were trained in British schools, the style is distinctly British and altogether charming. This telling description of a child with kwashiorkor is an example: "an unpleasant picture of unwanted misery." The book is well illustrated, and the various chapters give a brief but adequate list of references. This book should be required reading for physicians who deal with children in the subtropics and tropics. It could also be read with profit and pleasure by any physician who is interested in pediatrics in its broadest sense.

Grosse Nervenärzte. Band 2: 22 Lebensbilder. *In Gemeinschaft mit E. H. Ackerknecht et al. Herausgegeben von Kurt Kolle. Cloth. 29.40 marks; $7. Pp. 251, with 24 illustrations. Georg Thieme Verlag, Herdweg 63, (14a) Stuttgart, West Germany; [Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16], 1959.*

This is a sequel and companion to an excellent book reviewed in The Journal of May 19, 1956, page 294. The present volume offers biographies of Golgi, Nissl, Alzheimer, Brodmann, Cécile and Oskar Vogt, Helmholtz, Quincke, Esquirol, Meynert, Wernicke, Meyer, Gaupp, Marie, Babinski, Head, von Economo, Horsley, Dandy, Vincent, Dubois, and Simon. Each biography is the work of an author who is himself distinguished as a neurologist or psychiatrist, and those chapters which were originally written in English or French appear here in German. A concluding chapter sketches the development of institutions for teaching and research in neurology and psychiatry in France, Great Britain, Italy, Russia, Switzerland, Belgium, Holland, Scandinavia, Spain, and Portugal. Each chapter is illustrated with a portrait of the subject and closes with a brief bibliography. There is an index of names.

Thanks to both a felicitous choice of contributors and painstaking coordination by the editor each chapter gives not only an instructive account of the subject's scientific work but also an interesting picture of his personal life. In connection with the former there is enough detail, accurately presented by an authority, to make the book valuable to students interested in the development of fundamental ideas in scientific medicine. Examples are the thinking and experiments of Helmholtz on the nature of the nervous impulse and the growth of the idea of occupational therapy in the institutional practice of Simon. In connection with personal lives there are innumerable episodes and oddities, all related with tact and understanding. Examples taken at random are Calmiel's deception of Esquirol with a feigned grand mal seizure, Cushing's unfortunate remark that is believed to have started a life-long hostility between him and Dandy, John Horsley's unwillingness to paint from nude models, and Wernicke's enthusiasm for bicycle trips that led to a fatal collision with a lumber wagon in the Thuringian forest. This book is recommended especially to students of neuropsychiatry and of the history of medicine.

Pictorial Handbook of Fracture Treatment. *By Edward L. Compere, M.D., F.A.C.S., Professor and Chairman of Department of Orthopaedic Surgery, Northwestern University Medical School, Chicago, Sam W. Banks, M.D., F.A.C.S., Associate Professor of Orthopaedic Surgery, Northwestern University Medical School, and Clinton L. Compere, M.D., F.A.C.S., Associate Professor of Orthopaedic Surgery, Northwestern University Medical School. Fourth edition. Cloth. $7.50. Pp. 448, with 268 illustrations, line drawings by Harold Laufman, M.D., F.A.C.S., and Jean McConnell. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1958.*

This edition contains many changes in text and in thought from previous editions, and it represents a distinct advance over earlier volumes. The fracture treatment outlined is simply worded, direct and to the point, and amply illustrated. There are a minimum of those roentgenograms which so often are difficult to interpret when reproduced. The technique and methods explained are the standard ones generally in use throughout the United States. There is little attempt on the part of the authors to emphasize favored treatments of their own in certain fractures. They have in some instances described several methods of treating the same problem, but these methods are sound throughout and simply represent variations in technique that may be used to gain the same end.

This handbook is excellent for teaching purposes at the levels of both the medical student and the surgeon interested in orthopedics. It should be in the library of every general practitioner as well as that of the orthopedist. The table of contents shows excellent organization, beginning with some introductory remarks on fractures and their pathology with special reference to healing, and going on to diagnosis, emergency treatment, definitive treatment, and principles of care. The latter two-thirds of the book is so organized that one can turn to the part of the body involved and quickly find the type of fracture in which one is interested. Minor points of dispute might be raised on the discussion of the common ankle fractures, since there is a growing tendency throughout the country to perform open reduction and internal fixation more frequently than the writers advocate. Their conservatism in treating this problem gently is to be recommended, however, since what is standard practice in the hands of the expert is not always feasible in the hands of the general practitioner. This handbook is highly recommended to all traumatic and orthopedic surgeons and to students who are interested in fractures.

The Pneumoconiosis Problem: With Emphasis on the Role of the Radiologist. By Eugene P. Pendergrass, M.D., Professor of Radiology, University of Pennsylvania School of Medicine, Philadelphia. Cloth. $6.75. Pp. 146, with 53 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This book contains the entire manuscript of the Caldwell lecture which the author gave at the annual meeting of the American Roentgen Ray Society, Oct. 1, 1957. It is not a complete treatise on pneumoconiosis. Many phases of the problem of silicosis, asbestosis, and coal workers' pneumoconiosis are not considered. The effort has been directed largely toward a discussion of guide lines helpful in the interpretation of shadow patterns in the roentgenograms. These were gathered from records of silicosis in some 500 workers in industry who were exposed to free silica with essentially no contaminating dust. Many cases were followed up for over 20 years.

This book is aimed at interesting more radiologists in pneumoconiosis. The radiologist not only plays an important role in the diagnosis but also has increased opportunities for estimating pulmonary disability and complementing pulmonary physiological studies. The specific lesions of the three pneumoconioses are described, with emphasis on the necessity of evaluating shadows produced by blood vessels which simulate the pattern of nodulation. Many of the lesions of various forms of pneumoconiosis are not pathognomonic in themselves and simulate other diseases such as tuberculosis and Boeck's sarcoid. The roentgenographic appearance of the various pathological lesions is fully discussed and correlated with present concepts of disturbed pulmonary physiology in those states. Emphasis is placed on improving fluoroscopic and roentgenographic studies of chest physiology to improve present methods of estimating the extent of pulmonary disability. The most important chapters deal with the history of pneumoconiosis, types of pneumoconiosis, pathogenesis, and the classification of the roentgenologic manifestations. This monograph should be of value not only to radiologists but also to internists, chest physicians, industrial physicians, industrial hygienists, pulmonary physiologists, bronchologists, industrial engineers, thoracic surgeons, and medical students.

Radiation Biology and Medicine: Selected Reviews in the Life Sciences. Edited by Walter D. Claus. Prepared for United States Atomic Energy Commission. Cloth. $11.50. Pp. 944, with illustrations. Addison-Wesley Publishing Company, Inc., Reading, Mass., 1958.

The output of research publications on ionizing radiation since the advent of the atomic bomb and establishment of nuclear reactors has been truly staggering. In addition to thousands of individual journal articles and reports from governmental agencies, many volumes of symposiums on specialized topics have appeared. This book serves a real function in bringing together in a series of reviews an up-to-date account of the impact of atomic energy on such diverse fields as genetics, physiology, agriculture, and medicine, to name but a few, as well as on such varied but related problems as growth and aging, ecology, and bioeconomics. The editor makes it clear at the outset that the nature of the task has forced selection of only certain areas for review and, furthermore, that the scope of presentation has been limited essentially to work performed or in progress in the United States. Despite this fact, the coverage is excellent, and the 33 chapter headings have been selected with care. The authors present their specialties with competence and have written concisely and authoritatively, yet without "writing down" to their varied audience. Those who wish to refer directly to source material will welcome the extensive bibliographies accompanying each topic. The reviews of the medical uses of atomic radiation point up the wide application of radioisotopes today, as well as the development of accelerators and the nuclear reactor itself as a device for medical therapy and diagnosis. Already some 350 devices using radioactive cobalt (Co^{60}) as a teletherapeutic source are in use. The problems of instrumentation and dosimetry are well covered, and scanning technique, probably the most outstanding development in medical instrumentation within the past few years, comes in for its share of attention. In these days of international hysteria and debate, the basic material presented in this book should go far in providing factual information for the intelligent reader concerned about radiation hazards.

Reversible Renal Insufficiency: Diagnosis and Treatment. By Donald H. Atlas, M.D., Ph.D., F.A.C.P., Associate Professor of Medicine, Northwestern University School of Medicine, Chicago, and Peter Gaberman, M.D. Cloth. $7. Pp. 233, with 19 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1958.

The authors' experiences at the Cook County and Mt. Sinai hospitals in Chicago and a thorough review of the literature on the pathology, pathological physiology, and therapy of acute renal failure, with oliguria and uremia, have served as the basis for this monograph. More space is devoted to a review of conditions associated with elevated plasma calcium levels than to all forms of therapy for acute and chronic renal failure (50 compared to 40 pages). The review of hyperparathyroidism, "milk-alkali" syndrome, sarcoidosis simulating hyperparathyroidism, and other conditions associated with hypercalcemia is well worth study, as are the sections on lupus, gouty kidney, and other renal disorders. This can be recommended as a sound guide to the management of the oliguric and polyuric phases of acute renal damage.

Physiology of Exercise. By Laurence E. Morehouse, Ph.D., F.A.C.S.M., Professor of Physical Education, University of California at Los Angeles, and Augustus T. Miller Jr., Ph.D., M.D., Professor of Physiology, University of North Carolina Medical School, Chapel Hill. Third edition. Cloth. $4.75. Pp. 349, with 40 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1959.

This book constitutes a compact summary of material conventionally taught in connection with athletics. The opening chapters contain some of the classic fundamental facts about the histology, biochemistry, and physiology of voluntary muscles, with some of the more recent findings in these fields. Subsequent chapters are concerned with skills, muscular strength and hypertrophy, stress and endurance, energy requirements and efficiency, fatigue and recovery, training, nutrition, medical aspects of exercise, and physical fitness. Each chapter is followed by a bibliography, which is essential because of the brevity of many parts of the text. The book ends with a glossary, a convenient table of conversion factors for weights and measures, and a good index.

The scientific value of this book could have been greatly increased if advantage had been taken of the results of research in fields other than athletics, by greater concreteness in the discussions of the neurophysiology of muscular tone, by more frequent use of the precise vocabulary of kinesiology, and by eliminating some unfortunate terms, such as linear, lateral, eccentric, and concentric, inherited from the uncritical past. The statement (page 77) that "an attempt to contract the biceps voluntarily will not produce the movement" ignores the existence of the art of muscle control. The statement (page 253) that swimming develops "long" muscles is not borne out by the illustrations showing four men, one a swimmer, whose extremities are clearly of the same absolute and relative length. In most respects, however, the book deserves commendation as a compendium of scientifically verified facts of importance in physical education.

Lesions of the Lower Bowel. By Raymond J. Jackman, M.D., M.S., Associate Professor of Proctology, Mayo Foundation, Graduate School, University of Minnesota, Rochester. Cloth. $15.50. Pp. 347, with 131 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This is an excellent volume. The color plates depicting polyps, carcinomas, the lesions characteristic of ulcerative colitis, and other frequently seen lesions (as well as a few rare ones) are superb. This monograph is not a book on proctology or proctologic surgery per se, and apparently it is not intended to replace such a book in the physician's library. The style is rather that of a diagnostic study, dealing with the methods of performing proctologic examinations and the recognition of lesions most frequently encountered. This idea has been carried out clearly, concisely, and authoritatively.

The chapter on the technique of proctoscopy is well done. Step by step the reader is instructed in indications, preparation of the patient, positions, and the actual conduct of anoscopy and proctosigmoidscopy. The accompanying illustrations should clear up many misunderstandings held by beginners in these procedures. The technique of transrectal needle biopsy as it applies specifically to prostatic biopsy is included, surprisingly. Fifty-six black-and-white illustrations and a color atlas of 75 plates add a great deal to its usefulness. There are 28 chapters, each indexed with a subject-matter heading for easy reference. A wide diversity of medical men—the general practitioner, the gastroenterologist, the proctologist, and the general surgeon—will find this book a valuable addition to their working libraries.

QUESTIONS AND ANSWERS

SPEED OF TRANSFUSION

To the Editor:—*What is considered the maximum rate of administration of whole blood during transfusion?* *H. E. Rendel, M.D., Mexico, Ind.*

Answer.—The maximum rate of administration of whole blood during transfusion is considered to be about 250 ml. per minute. In actual practice the maximum rate is related to the amount of blood that can be forced through a 15-gauge needle into an accommodating vein or veins. Several problems may result from the rapid administration of a large amount of whole blood. The first is the remote possibility of citrate intoxication, although this rarely, if ever, happens. A second complication that can follow the rapid administration of whole blood in massive amounts is thrombocytopenia with serious clotting disturbance. This has occurred clinically and can be produced experimentally. Overloading the circulation can result in pulmonary edema. Good clinical judgment is always necessary in deciding how much blood should be given in what period of time.

DIAGNOSIS OF RENAL TUBERCULOSIS

To the Editor:—*In this area, there is a difference of opinion as to the best method of identifying tuberculous organisms in the urine. Staff members at one hospital insist that urine cultures provide the most consistent results. At another hospital, they believe that urine cultures are not as effective as guinea pig inoculation. Should not all methods, namely, acid-fast stain, culture, and guinea pig inoculation, be used whenever possible? There is also a difference of opinion regarding the collection of the urine sample. Some believe that only a 24-hour specimen provides any degree of accuracy, while others accept a morning specimen.*

Carl K. Pearlman, M.D., Santa Ana, Calif.

Answer.—No dependence should be placed for diagnosis, especially for initial diagnosis, solely on microscopic examination of the urine, especially voided urine, because of the constant presence about the external urogenital orifice of saprophytic, acid-fast bacilli microscopically indistinguishable from Mycobacterium tuberculosis. These deceptive saprophytes are only with difficulty excluded from urine specimens, even from catheterized specimens. Urine for bacteriological examination should be obtained by means of a sterile catheter to avoid the inevitable contamination of voided specimens. If voided urine is used, 24-hour specimens are preferable because they are more likely to contain tubercle bacilli than a single voided or catheterized specimen, since the bacilli are often shed intermittently. However, 24-hour specimens are usually heavily contaminated unless refrigerated and require decontamination with consequent loss of some of the tubercle bacilli.

The controversy over culture vs. guinea pig inoculation continues in the absence of general acceptance of a culture procedure. The number of cultures, decontamination, and concentration methods presented in the literature testifies to general dissatisfaction with (but not necessarily to inferiority of) existing procedures. A strictly fair comparison between culture methods and guinea pig inoculation requires that the same amount of the same material be used to inoculate, as nearly simultaneously as possible, guinea pig and cultures in a sufficiently large number of cases to yield a statistically significant result. The patients selected should be those known to be shedding tubercle bacilli in numbers sufficiently small to test the sensitivity of each method, or else the comparisons should be based on such quantitative data as colony counts and rapidity of growth. It is also essential that culture methods be carried out exactly as recommended by their sponsors. Such studies are rare and, with regard to urine, virtually nonexistent. In too many studies of this sort, human and other variables, some known and some unknown, seem to have played a significant role.

There are now probably a dozen or more culture methods which, properly handled, yield diagnostic results as reliable as, and often more rapidly than, guinea pig inoculation. Discussions of these may be found in the literature. In any case, the identity and virulence of any acid-fast organism isolated in pure culture from urine or other contaminated material (such as sputum) must, at least for primary diagnosis, be verified by guinea pig inoculation. Additional physiological tests other than, or in addition to, guinea pig inoculation may be required in the case of some of the so-called atypical acid-fast bacilli recently recognized as possibly involved in tuberculosis-like infections. The use of guinea-pig inoculation alone would fail to detect a number of these atypical strains. Furthermore, pure cultures are desirable for sensitivity testing.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

The more methods that are used in any diagnostic test, especially in biological diagnostic tests such as cultural procedures, the more likely is a reliable result to be obtained (assuming minimal probability of obtaining a positive result). For example, the use of cultures and guinea pig inoculation together is more likely to give a dependable result in a minimal time than the use of either alone. The inoculation of 10 culture tubes is preferable to the inoculation of 1. In short, the wider the net, the more the fish. So far as procedures are concerned no specific recommendation need be made, but it may be said that, for urine, centrifugation of the specimen for 30 minutes at 4,500 rpm is necessary. If there is no flocculation or sediment a small amount of flocculating agent, such as ferric chloride, in urine made slightly alkaline with sodium bicarbonate, is advisable to gather the bacilli and sediment them. If the sediment is not heavily contaminated it may be used to inoculate, directly, slants of some medium such as the Holm-Jensen-Lowenstein medium, the Frobisher-Petragnani medium, or one of the later-devised blood or egg mediums. Contamination may be controlled by adding penicillin and cycloheximide to the culture medium. If heavily contaminated, preliminary decontamination with sodium hydroxide or sulfuric acid may be used, as for sputum, but these are toxic to M. tuberculosis and are to be avoided in favor of the antibiotics.

CORNEAL HERPES SIMPLEX

To the Editor:—*A patient has had recurrent dendritic ulcer of the right cornea for five years. Recurrences are two to four weeks apart, and each attack has left the cornea partially denuded and has caused an irregular surface. Attacks last one or two weeks. Several physicians have recommended a corneal transplant as a means of preventing future ulcerations and to improve the present vision (20/400 in this eye). About one-half of the corneal surface has been affected. X-rays of the sinuses revealed a mild pansinusitis, and in July the ethmoid and sphenoid sinuses were operated on and the nasal septum was straightened. Autogenous vaccine was prepared and is still being given. The patient has taken vitamin B complex daily for the past five years, eats well, feels well, and has no chronic inflammatory lesion of any kind. The eye has been cauterized at least 20 times with iodine; the entire cornea has been scraped about three times. Every known ophthalmic ointment has been used, and all eventually caused irritation and had to be replaced by a milder preparation; 20 cc. of immune serum globulin has been injected intramuscularly on two occasions one month apart. Also, 20 smallpox vaccinations were administered twice a week. Large amounts of vitamin C are taken daily. It was recommended that, after subsidence of each acute phase, an ophthalmic ointment or solution be given twice a day, but since this has not prevented a recurrence of further ulcers all medicaments have been withdrawn. What further steps can be taken to stop the attacks? Is any research being done at present for such a condition and, if so, where? Have any ophthalmologists in the United States had a number of such cases, and were they successful in treating such a stubborn case? Would the use of contact lenses improve the vision, or would they further damage the cornea or excite an attack? Are sufficient statistics available to indicate or warrant transplantation in this case?* *M.D., New Jersey.*

Answer.—In the past 10 years there has been a marked increase in the frequency of chronic herpetic corneal ulcers, especially of those that lead to perforation. This is attributed to the widespread use of corticosteroids and antibiotics in the treatment of herpes simplex infections. The herpes simplex virus is one of the smallest known and is not affected by topical or systemic medication. Recurrences are brought about by multiplication of the virus within the tissues because of reduced local tissue immunity. They may be associated with upper respiratory infections, fever, menstruation, and minor ocular trauma, but for the most part no cause can be found. The mainstay of treatment has been destruction of the cells containing the virus with iodine, ether, or similar chemical cautery. As the inquiry indicates, many medicaments have been recommended to prevent recurrences and these are frequently without value.

Much research is being carried out on virus infections of the eye. The current status of these studies is synopsized in the Symposium on Viral Keratoconjunctivitis (*Am. J. Ophth.* 43:3 [part 2], 1957). Many ophthalmologists in the United States have seen a large number of patients with corneal herpes simplex, but because of the nature of the disease no particular method of therapy is consistently successful. A contact lens will improve vision only if the visual diminution results from an irregularity of the cornea. Generally, a contact lens is contraindicated in an eye in which herpes simplex infections recur frequently.

Therapeutic lamellar grafting is indicated in patients with chronic superficial ulcers that fail to heal after two or three months' treatment; in those with much deeper, more extensive ulcers that fail to respond in two or three months to a variety of treatments; to prevent frequent recurrences of dendritic ulcers; and in patients with chronic disciform ulcers that have perforated. Contraindications to lamellar keratoplasty are secondary infection by bacteria or fungi, glaucoma, and iridocyclitis. Lamellar keratoplasty has been performed in a number of patients with corneal herpes simplex. Frequently a penetrating graft is necessary as a secondary procedure to improve vision. The purpose of the therapeutic lamellar graft is to remove all of the diseased corneal tissue containing the virus. Since only a portion of the cornea is removed and the globe is not entered, the operation is not as technically difficult as a penetrating keratoplasty. It may frequently be associated with a gratifying improvement in vision. With a history of recurrent infections over a period of five years, this would seem to be an ideal case for corneal transplant, as suggested by the physicians who have already seen this patient.

BLOOD PRESSURE TRACINGS

To the Editor:—*Has anything practical and inexpensive been developed by which blood pressure may be graphically recorded in the office, thus removing the human element in its accurate interpretation? Do the occasional relatively wide variations in blood pressure readings recorded by different "competent" physicians or even by the same observer on repeated examinations represent true labile changes?* *M.D., California.*

Answer.—No practical, simple, and inexpensive instrument is available for graphically recording blood pressure in the office. The techniques used in physiological and crime detection laboratories are complicated and delicate. Furthermore, these instruments do not indicate precisely the level of diastolic pressure, concerning which there is widespread lack of unanimity even with the auditory method. The wide variations in observed blood pressure readings under accurately controlled conditions do represent actual fluctuations in pressure, but this fact need not be ominous or lead to concern. In the absence of pheochromocytoma, wide and rapid fluctuations are commonly seen as the result of the state of mind—rage or fear in extreme instances, concern, apprehension, a bad day or night, the novelty of coming to a strange physician, or where a momentous decision is to be expected. A man who has been examined for life insurance may be somewhat apprehensive. His pulse is rapid and his blood pressure elevated, so either he is rejected or his premium is increased. When he is seen by the family physician or a consultant who gains his confidence, his pressure is repeatedly found to be normal. One can observe a rapid fall in pressures as the patient's mind is directed from the realization that the pressure is being taken, and often it can be observed to rise as he again becomes aware of the procedure. No matter how satisfactory and how frequently this fall to normal may be observed in the office of a neutral observer, the pressure will invariably be elevated when he returns to the insurance examiner. Similar reactions are seen frequently in women referred for a gynecological examination and, in World War II, in young healthy men examined for officers' training. The above facts are the basis for the sedation test, in which the subject is given a relatively large dose of a sedative or tranquilizer, after which serial readings are taken every half hour for five or six periods. This may be considered a legitimate procedure in hyperreactors if the examining physician is informed of the program and is aware that no true blood pressure reducing or vasodilating preparation is being used. Thus, these fluctuating readings represent actual variations in levels of pressure, but the interpretations of these changes should be made with caution and after ascertaining the facts and behavior behind the changes.

ERYSIPELAS AND CANCER

To the Editor:—*Recently, a lawyer asked about an article which advocated the use of erysipelas in the treatment of advanced carcinomatosis. The lawyer's secretary has generalized carcinomatosis, and he would like to know if she could be benefited by this treatment. Where and by whom is the experimental work on this form of treatment being done?* *A. A. Fink, M.D., Topeka, Kan.*

Answer.—The observation that in one patient who had been operated on five times for sarcoma there was no recurrence after two attacks of erysipelas prompted the late Dr. W. B. Coley to study the effects of induced streptococcic infections on tumors. Difficulties encountered included patient immunity and occasional death from infection. Heating or filtration appeared to destroy the effectiveness of the culture. Eventually, a mixture of toxins from erysipelas producing streptococci and Serratia marcescens came to be known as Coley's toxin. This material received extensive trial. All but a few preparations were weak and variable, but there are a number of reported tumor-free survivals of 20 to more than 40 years' duration. A review of the influence of bacterial infection and of bacterial products (Coley's toxin) on malignant tumors in man has been made by Nauts and associates (*Acta med. scandinav.* [supp. 276] 145:1, 1953). Unfortunately, it is impossible to determine the percentage of objective remissions achieved from the available data. The effectiveness of this form of therapy appears to be related to the production of a severe local inflammation augmented by a systemic febrile reaction. Daily injections for many months, sometimes interspersed with short rest periods, are required. It is necessary to provide means for evacuation of large quantities of necrotic tumor tissue to prevent toxemia from absorption. A more recent extension of this work has been the use of purified polysaccharides from bacterial cultures such as S. marcescens, but the reported results from such therapy are not impressive.

REACTION TO CHRYSOTHERAPY

To the Editor:—*A patient with rheumatoid arthritis received an initial injection of 25 mg. of gold sodium thiomalate. Twenty-four hours later he experienced swelling and itching of the scrotum and lower lip. The only other drug taken concurrently was dextropropoxyphene (two capsules every three hours for two doses). The literature concerning toxic reactions to gold mentioned pruritus and dermatitis but not an immediate urticarial reaction. Could the gold have caused this reaction? Paul Gerber, M.D., Philadelphia.*

Answer.—Immediate allergic reactions to the administration of gold, while rare, are not unknown. Either this or the other medicament taken concurrently could have been the precipitating factor in this patient. Probably 10% or less of patients will note an acute exacerbation of rheumatic symptoms within 24 to 48 hours after the administration of gold, and this is generally considered to be an allergic manifestation. It is not an indication for discontinuing treatment but rather for decreasing the size of the dosage. If the case that forms the basis of this inquiry is one in which gold is indicated, a single dose of 1 mg. of gold sodium thiomalate could be given intramuscularly at a future date, and if no untoward reaction occurred to this dose an injection of 5 mg. could be given one week later. If no reaction is noted the dose could then be increased 5 mg. each week to a maintenance dose of 25 mg. The appearance of allergic manifestation after the administration of any of these injections would be a sign for discontinuance of this type of therapy. Because of the potential toxicity of chrysotherapy, it seems wise when instituting such treatment in any patient with rheumatoid arthritis to use only 5 or, at most, 10 mg. of gold as an initial dose and to increase to the maintenance dose of 25 or 50 mg. by increments of not over 10 mg. per week.

BOILED PEANUTS FOR DIARRHEA

To the Editor:—*A 34-year-old woman who had had intermittent abdominal pain for four years had an exploratory laparotomy in November, 1956. At that time a terminal ileitis involving the distal 10 in. of the ileum was found. The terminal 2 ft. of ileum were resected and an end-to-side ileoascending colostomy was performed after closure of the ileocecal opening by inversion. There were no skip areas, and no other abdominal lesions were noted. The pathological report showed chronic granulomatous inflammation of the terminal ileum compatible with regional ileitis. After operation the patient recovered, but diarrhea has persisted and has not responded to ordinary therapy. In February, 1957, a complete gastrointestinal examination was done with negative findings and she was given prednisone; this therapy was continued throughout the year with the patient gradually returning to normal weight and vigor. Therapy was stopped in March, 1958, but she continued to have six to eight stools a day with mucus but no blood. The patient has found that if she consumes a pint or more of boiled peanuts daily the symptoms are controlled. This does not happen with folic acid, vitamin* B_{12}, *antispasmodics, pancreatin, or any other dietary measure. On several occasions when the peanuts were not taken the diarrhea returned, only to disappear again with their ingestion. Please give information that would lead to some specific form of therapy.*

C. H. Richardson Jr., M.D., Macon, Ga.

Answer.—The control of diarrhea by boiled peanuts in a patient who has had a resection of the distal ileum is a most interesting observation. This consultant knows of no explanation for this, but peanuts and other nuts contain a number of constituents that have physiological or pharmacological action. Several glycosides that have a goitrogenic action have been isolated from edible nuts (*J. Nutrition* 66:291, 1958). The outer red skin-covering of certain nuts has been found to contain anthocyanins and tannins. Such compounds might conceivably decrease the activity of the intestinal mucosa. An alcohol-soluble material has been found in peanuts which may have an influence on blood coagulation in hemophilia. Further study of the effect of boiled peanuts in the therapy of diarrhea appears to be warranted.

METABOLIC RATE IN AN AMPUTEE

To the Editor:—*Please give advice on the determination of basal metabolic rate in a patient suspected of having hypothyroidism. The difficulty lies in the fact that this patient has had both legs amputated at midthigh because of gangrene, complicating diabetes mellitus. The problem is the determination of the patient's body surface. Her blood cholesterol level is within normal limits. The protein-bound iodine and radioactive iodine uptake tests are not locally available.*

Leo Lewin, M.D., Mount Arlington, N. J.

Answer.—The true surface area of this patient can be determined with reasonable accuracy by making a series of linear measurements of body parts and applying the "linear formula" as described by DuBois and DuBois (*Arch. Int. Med.* 15:868, 1915). Unfortunately, this will not solve the problem. Normal standards for calories per square meter (or liter of body water) are entirely empirical, i. e., they are merely average values observed in healthy, intact persons. They are not applicable to amputees because the various body parts are far from uniform in terms of calories per square meter. For example, the bilateral, midthigh amputation probably reduced this patient's surface area by about 30% but her basal heat production by less than 10%. The simplest procedure is to use the patient's preamputation height and weight in calculating a basal metabolic rate in the usual fashion; then, in order to make allowance for a 10% reduction in calorie output due to the amputation, set the "normal range" for this patient at —25% to +5%. In view of the uncertainty in this procedure and because of the propriety of conservative management of hypothyroidism in the presence of diabetes, a protein-bound iodine level determination would be desirable. This can be done on a mailed plasma sample.

USE OF THIOPENTAL IN LABOR

To the Editor:—*How soon does thiopental reach the infant circulation if used in cesarean section? What are its advantages and hazards?*

D. D. Dieter, M.D., Eustis, Fla.

Answer.—On the basis of work by Crawford (*Brit. J. Anaesth.* 28:146, 1956) and others, it is generally believed that thiopental, if used for cesarean section, passes immediately from the mother to the fetus. While certain advantages are associated with the use of thiopental for cesarean section (pleasant, easy induction of anesthesia, control of eclamptic convulsions, or decreased incidence of postanesthetic vomiting), definite hazards are involved. These include respiratory depression of mother and, especially, of the infant and increased possibility of severe respiratory spasm if the mother has recently ingested food. While the drug is not contraindicated for use during cesarean section, it should be given only with full appreciation of the risks involved.

HYPERKERATOSIS

To the Editor:—*An 11-year-old boy developed a thick scaling cracking of the palms of the hands and soles of the feet four years ago. This resembles ichthyosis but is limited to the palms and soles. The condition has remissions and exacerbations which occur every three or four months. The soles of the feet have been relatively free from the scaling but appear dry. At the times of exacerbation of the condition the nails become brittle and break easily. The boy's general health has remained good. Many treatments have been tried with little success. In general, the most successful has been applying simple softening ointments to the skin and waiting from two to three weeks for the natural remission. Would this condition suggest a deficiency state? What tests and treatments might be beneficial?*

Dwight E. Conklin, M.D., Oakland, Iowa.

Answer.—Hyperkeratosis of the palms and soles (keratosis palmaris et plantaris) usually begins in childhood. Most cases are familial and in such patients no deficiency state has ever been demonstrated. Red, thickened, scaly palms and soles have been described as a manifestation of psoriasis and of pityriasis rubra pilaris. They may result also from mycotic infection, especially with Trichophyton rubrum. Numerous repeated examinations of the scales under potassium hydroxide and cultures must be done to exclude T. rubrum, particularly in view of the nail changes described in this case. In keratosis palmaris et plantaris bland lubricants and the avoidance of irritants provides comfort; a 1 or 2% solution of salicylic acid may be incorporated to promote peeling. No internal therapy (vitamin A, thyroid, or gelatin) has proved to be of value consistently. The prognosis should be guarded. Generally, patients retain the condition throughout life.

HAZARDS OF METALLIC PAINT

To the Editor:—*Is there a safe process by which a person can be covered with bronze or metallic paint?* *John H. Calvert, M.D., Pierce, Neb.*

Answer.—No form of this practice may be regarded as proper. At best, all such paints constitute a physiological insult to the skin. At present, real metal powders ordinarily have given way to plastic powders made to resemble metals or to fluoresce. Vehicles of the varnish type have disappeared, and corn syrup and glycerine are currently in favor. These agents do not dry the skin and may be readily washed from the body.

COMPOSITION OF COMEDONES

To the Editor:—*What is the composition of comedones? Has any work shown whether they are related to elevated blood cholesterol level, lipids, or androgens? Have there been any surveys of incidence of acne among different races and different dietary groups?*

G. H. Hoehn, M.D., San Gabriel, Calif.

Answer.—Some information, though fragmentary, regarding each of these questions is contained in a publication by Washburn and Liese (*J. Lab. & Clin. Med.* 41:199, 1953). These authors also found that the cholesterol content of sebum was higher than normal in an adult with testicular insufficiency. The sebum cholesterol level was elevated to that usually found prior to puberty, and it dropped after testosterone therapy. Investigations of the composition of comedones are scanty, and further studies might be valuable. There are, however, several reliable reports on the composition of sebum in acne vulgaris. A concise review was published recently by Wheatley (*Practitioner* 180: 580, 1958). Kile and co-workers (*Arch. Dermat. & Syph.* 61:792, 1950) did not find any significant deviation of the sebum composition in skin areas affected by acne from that in unaffected areas of patients with acne or of normal persons. Dubovyi (*Vestnik Vener. Dermat.*, no. 2, p. 22, 1955), however, demonstrated a higher ketosteroid percentage in subjects with acne, and Wheatley's recent studies are highly suggestive of a lower concentration of unsaturated fatty acids. As pointed out by Rothman and Schaaf (*Handb. d. Haut-u. Geschlechtskr.* 1:161, 1929) and again by Rothman in his textbook "Physiology and Biochemistry of the Skin" (Chicago, University of Chicago Press, 1954), ingestion of large amounts of cholesterol with the food can increase the cholesterol concentration in sebum.

TRACTION FOR WHIPLASH INJURIES

To the Editor:—*How useful is intermittent traction in the treatment of whiplash injuries or when pelvic traction is desired? Are the motorized traction apparatuses good for this purpose? If so, what types are best, and where may they be obtained?*

Delbert L. Warwick, M.D., Costa Mesa, Calif.

Answer.—The exact pathogenesis of whiplash injuries has not been determined. The acute episode probably is a sprain, with tearing of certain of the ligaments in the neck. There may be disturbances in the facet joints, as well as the lateral vertebral joints. Herniation of the nucleus pulposus also may occur as a result of whiplash injury. In none of these circumstances, with the possible exception of herniation, can benefit be expected from traction. Cervical traction probably has no justification in the treatment of so-called whiplash injuries. This applies during the acute period and for several weeks after the injury. Degenerative changes may result from whiplash injuries, with narrowing of the intervertebral disks, formation of hypertrophic spurs, and, sometimes, appearance of radicular symptoms and signs or both. During this phase cervical traction may be tried for its effect. If helpful, it may be continued. It is not clear whether the questioner means to use pelvic traction in treatment of whiplash injury. There seems to be no rationale for its use in this condition. It is used as part of the conservative management of lumbar disk affections. Motorized traction apparatuses are helpful in treating certain cervical syndromes, chiefly those due to degenerative disease, but the usual whiplash injury is not in this category.

FILLINGS AND LEUKOPLAKIA

To the Editor:—*Is there any evidence that mercury amalgam and gold fillings in the same mouth predispose to the formation of leukoplakia?* *M.D., West Virginia.*

Answer.—There is no definitive evidence to support the concept that metallic fillings of varying electrical potentials predispose to oral leukoplakia. When an electrical force is produced under these circumstances it is on an intermittent basis and in a limited time ceases to repeat itself. Thus, if the electrical force can be considered trauma, it is not a chronic irritation. Patients may be aware of a salty taste which they attribute to the opposing metallic fillings, but this is often erroneous.

SCHMORL'S NODULES

To the Editor:—*A patient who died of multiple myeloma had showed Schmorl's nodules in an x-ray film about 11 years earlier. Should a patient presenting such nodules receive periodic bone surveys for several years?*

M.D., California.

Answer.—Schmorl's nodules, an acquired process, represent extrusion of a portion of the nucleus pulposus through the cartilaginous plate of the intervertebral disk into the body of the vertebra. They accompany the condition occurring in adolescents variously called juvenile kyphosis, Scheuermann's disease, or vertebral epiphysitis. They are also commonly found late in life and have no clinical significance except that their presence indicates some degeneration of the intervertebral disk. Periodic bone surveys are not indicated. The nodules have no relationship to and should not be confused with myeloma.

REJUVENATION

To the Editor:—*Is there any contraindication to the administration of gonadotropins to elderly men for possible rejuvenation or stimulation of their potency? Many advertisements recommend such treatment. How effective have these agents been for these purposes? What are the upper limits of safety for the continued use of these drugs?* *M.D., Missouri.*

Answer.—There are no specific agents for the purpose of rejuvenation, but there are few, if any, contraindications to the administration of gonadotropins in small amounts, such as 0.167 mg. of estrone plus 1.67 mg. of methyltestosterone in a capsule given three times a day. However, the activity of prostatic malignancy is affected by the intensity of androgenic stimulation.

CLIMATE AND RHEUMATOID ARTHRITIS

To the Editor:—*A 17-year-old girl has had severe rheumatoid arthritis for about a year. At present she is much improved. She is now making plans for college. Would she be better in Denver than here in Minnesota?* *M.D., Minnesota.*

Answer.—This consultant knows of no scientific evidence to indicate that climate is an important factor in rheumatoid arthritis. Some patients with rheumatoid arthritis feel better in a warm, dry climate, and some feel better in a relatively dry climate of higher altitude. In any climate, good treatment for the disease needs to be carried out in order to obtain the best results in controlling the disease. Since the patient has improved in her own environment, she would probably get along well in college either in Minnesota or Colorado, providing she continued to get good medical care.

ANTIBIOTIC COMBINATIONS

To the Editor:—*Is it ever practical to use both penicillin and a tetracycline simultaneously in the treatment of an ordinary and uncomplicated infection, such as otitis media or acute tonsillitis?*

M. A. Cornwall, M.D., Hudson, Wis.

Answer.—Combined antibiotic therapy may be used in patients with mixed infection to prevent the emergence of resistant bacterial mutants and for additive or synergistic effects against relatively resistant organisms. In ordinary uncomplicated otitis media or acute tonsillitis, it is needless, impractical, and illogical to use penicillin and a tetracycline simultaneously.

WOLFF-PARKINSON-WHITE SYNDROME

To the Editor:—*In the Wolff-Parkinson-White syndrome, during episodes of tachycardia, does the abnormal conduction pathway revert to normal, giving a QRS complex of normal measurements and form?*

Irving Berlin, M.D., Newport News, Va.

Answer.—During the episode of tachycardia, the QRS complex usually is of normal form and duration.

PROPHYLACTIC SURGERY IN CANCER

To the Editor:—*The answer to the question on prophylactic surgery in cancer, which appeared in* The Journal, *Jan. 10, 1959, page 183, needs some elaboration. The question is not whether an operation should be performed but whether it would be justifiable for three sisters, aged 38 to 42, to have prophylactic bilateral simple mastectomy when each of four older sisters has died from metastasis of breast cancer, within less than five years after radical mastectomy, at ages between 45 and 55 years. The answer to this seems to be an unequivocal "It would be justifiable." Whether it should be done is a matter of personal opinion and depends on such factors as general health, emotional make-up, and marital status.*

Although mastectomy is a traumatic experience for a woman, as the answer states, awareness of the fact that four sisters developed and died of cancer of the breast in the age period a woman is entering is probably at least as traumatic psychologically as the mastectomy and possibly more so. Since all four sisters died within five years, although the lesions had been found early, one can assume that they had unusually invasive malignancies and the same type would conceivably develop in the remaining sisters. This should be one more reason for a prophylactic operation. Where the psychological impact of mastectomy may be too damaging, it may be advisable to excise the glandular tissue of the breasts without removal of skin and nipple and to replace it by implantation of some foreign material.

Hans L. Popper, M.D.
185 N. Wabash Ave.
Chicago 1.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*In the opinion of this consultant, prophylactic mastectomy under the stated circumstances is not justifiable. Furthermore, the foreign material generally used for the replacement of the normal gland structure is potentially carcinogenic, and such a practice should be mentioned only to be condemned.*

ELECTROSHOCK THERAPY

To the Editor:—*I would like to refer readers of* The Journal *to* Time *magazine, Jan. 26, 1959, page 23, and the article about "Plaintiff's Counsel," which tells the story of the "King of Torts," Melvin M. Belli, whose pet peeve is doctors and who presently is performing in Columbus, Ohio. In* The Journal *for Jan. 24, 1959, page 419, a question is asked about ventricular fibrillation as a complication of electroshock treatment. In answer to the question: "Does the rapidity of injection of succinylcholine have any bearing on the incidence of ventricular fibrillation?" the second consultant very properly adds that the management of circulatory arrest in the course of electroshock therapy depends, as in other such cardiac emergencies, on establishing as quickly as possible the type of abnormal mechanism, whether rapid ectopic impulse formation or cardiac standstill. Here the consultant goes out of his way to make a statement which I predict will warm the heart of Mr. Belli; he says, "Such a distinction is greatly aided by the monitoring of cardiac events on a cardioscope, which should be part of the routine equipment in any setup for shock therapy."*

How can a clinical psychiatrist, even in a hospital, afford to include cardioscopy as a routine measure for shock therapy? I would question whether 1% of the treatments in the United States are given with a cardioscope to monitor the cardiac events. Yet this statement would lead one to believe that without the cardioscope the physician has not taken reasonable precautions, and I would predict that this statement will be used to place in jeopardy the practice of well-qualified psychiatrists who have given thousands of patients electroshock treatment without even suspecting that a cardioscope should be "routine equipment."

I believe that statements appearing in the Questions and Answers section should be carefully read for possible medicolegal angles, particularly when the consultant is surrounded by the unlimited services of a large medical center and is not familiar with the conditions under which the average physician attempts to carry on the practice of medicine.

George T. Harding, M.D.
445 E. Granville Rd.
Worthington, Ohio.

The above comment was referred to a consultant, and his reply follows.—Ed.

To the Editor:—*Doctor Harding states that less than 1% of the shock therapy treatments given in the United States are given with a cardioscope to monitor the cardiac events. He is apparently concerned over the fact that, inasmuch as the cardioscope is not routinely used, the result may be to aid malpractice attorneys in planning cases against physicians where a cardioscope might have avoided a bad result from shock therapy. The fact that a consultant may recommend the use of a cardioscope would not establish negligence on the part of the physician who failed to use such equipment unless the plaintiff could establish that the use of such equipment was routine and standard. If less than 1% of the treatments in this country are given with a cardioscope to monitor the cardiac events, a plaintiff's lawyer would not be able to establish negligence because of the failure to use such equipment. This consultant does not believe that a medical consultant should be burdened with medicolegal implications where his recommendations involve matters relating to better medical care nor that there is any need to review routinely strictly medical matters for medicolegal implications. Although it is felt that physicians should be aware of their legal responsibilities in the practice of medicine, it seems that some practitioners have been oversold on the idea.*

RECURRENT INFECTIOUS MONONUCLEOSIS

To the Editor:—*In the questions and answers section of* The Journal, *Dec. 27, 1958, page 2332, no specific case is cited in reply to an inquiry as to whether infectious mononucleosis has been reported to occur a second time in the same patient. I should like to call attention to a report by Paterson and Pinniger (Brit. M. J. 2:476, 1955) describing three attacks of infectious mononucleosis in a young man at the ages of 14, 18, and 21 years. The diagnosis was supported by laboratory evidence in each instance. This is a most unusual occurrence. A review of reported cases of recurrence by these authors disclosed only one other case in which the diagnosis was confirmed by the Paul-Bunnell reaction.*

Harry Wiener, M.D.
630 Flushing Ave.
Brooklyn 6, N. Y.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*The difficulties in studying the recurrence of infectious mononucleosis are well illustrated in the paper by Paterson and Pinniger cited in the comment, since, even in the thoroughly investigated case reported, they were unable to secure the hematological findings or the results of the Paul-Bunnell test when the first two attacks occurred. They satisfied themselves,* *however, that at least the second attack—suffered while the patient was serving in the Royal Air Force—was genuine, as shown by laboratory tests. When he was sick at the age of 14, "he had symptoms of infectious mononucleosis [and] the white blood picture was said to be suggestive of the disease and the Paul-Bunnell test to be positive." In the second case mentioned in the comment, presumably the one reported by Rugg-Gunn* (Proc. Roy. Soc. Med. 47:759, *1954), the patient had the clinical findings of infectious mononucleosis at the age of 6 but hematological investigation was not done. Eight years later he again showed enlargement of the glands of the neck; blood examination was done, and the diagnosis of "glandular fever" was given. At the age of 20 he once more showed symptoms of the disease, and at that time both the differential counts and the Paul-Bunnell test confirmed the diagnosis. In the paper by Paterson and Pinniger, the findings of Bernstein in his review of the disease are cited. Of five cases of recurrence, in only one was the diagnosis confirmed during the second illness by the Paul-Bunnell test. Here the patient had initially an icteric type of illness, which was followed a year after recovery by an episode of glandular enlargement with fever. As the Paul-Bunnell test was not done on the first occasion, it seems that the possibility of this case being infectious hepatitis at that time cannot be entirely excluded. It appears, therefore, that the recurrence of infectious mononucleosis is rare, at least as judged by the cases reported in the medical literature.*

CELERY CONTACT DERMATITIS

To the Editor:—*In reading the answer to the question on celery contact dermatitis, which appeared in* The Journal, *Jan. 10, 1959, page 185, it occurred to me that there might be another explanation for this syndrome. This dermatitis, like that associated with parsnips* (Acta dermat.-venereol. 25:179, *1944), may be due to the presence of photodynamically active furocumarines in these plants. Members of the psoralen family are present in such substances as citrus oils and bergamot, the best known being methoxsalen or 8-methoxypsoralen, from Ammi majus L. Aside from the fact that workers at the University of Oregon School of Medicine have recently demonstrated significant amounts of psoralens in celery, the natural history of the dermatitis suggests contact with a photodynamic agent. The statement that "the harvesters were afflicted" would be true because these workers would also be exposed to ultraviolet energy. It is also stated that the eruption appeared "within 24 to 48 hours." A latent period of one to two days is usual after use of the psoralens. The eruption consisted of "erythema, edema, vesicles, and large bullae." This was presumed by the consultant to be on the hands, forearms, and perhaps the face and neck." These are precisely the areas either certainly or very likely to be exposed both to celery oil and to sunlight. Also, how better could one describe severe sunburn?*

In the light of these data, a rational, preventive approach may be recommended for trial. Psoralens augment the skin's response to ultraviolet energy and have no demonstrable topical activity in the absence of that energy. Field workers should be advised to avoid skin contact with the essential oil and direct solar exposure. Such measures as wearing sleeves rolled down and wearing gloves would help in two ways: contact with the plant would be minimized, and ultraviolet rays would be screened out. An extensive publication on psoralens and radiant energy (J. Invest. Dermat., *supp., Feb., 1959) should be consulted for further information on this fascinating subject.*

Harold A. Tucker, M.D.
The Upjohn Company
Kalamazoo, Mich.

NEURITIS OF RECURRENT LARYNGEAL NERVE

To the Editor:—*In response to a question and answer regarding neuritis of the recurrent laryngeal nerve, which appeared in* The Journal, *Dec. 27, 1958, page 2329, I noticed that the consultant failed to mention the possibility of laryngeal crises associated with tabes dorsalis (Fien and others,* Am. J. Syph. 36:201, *1952). The possibility of laryngeal crises associated with tabes dorsalis should be borne in mind in such a patient as that described in the question.*

Donald F. Proctor, M.D.
819 Park Ave.
Baltimore 1.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*Although the correspondent is correct in pointing out the possibility of laryngeal crises in tabes dorsalis, this is a rare occurrence and reference to it is encountered much more frequently in earlier medical literature than in recent years, probably because of the decreased incidence of central nervous system syphilis. Laryngeal findings in tabes are usually preceded or accompanied by other signs and symptoms of the disease. It was assumed from the initial query that the various diagnostic studies on the patient in question had included a thorough physical examination and complete laboratory tests.*

TREATMENT OF PULMONARY EMPHYSEMA

George N. Bedell, M.D.
and
Paul M. Seebohm, M.D., Iowa City

The etiological diagnosis is of basic importance in patients with emphysema because the distinction between primary and secondary types decides the plan of treatment. The general aim of treatment is to keep the patient active; to preserve as much lung tissue as possible, and to maintain comfort. In primary emphysema, breathing exercises and such expectorants as potassium iodide are helpful, and in severe cases oxygen is indicated if used with due caution. But in secondary emphysema it may be necessary to use bronchodilators and steroids to combat underlying bronchial asthma, antibiotics to stop destructive infections, and other therapy directed at the original cause.

PULMONARY emphysema is a disease characterized pathologically by loss of elastic tissue and destruction of alveolar walls in the lung leading to the formation of enlarged air sacs. The physiological abnormalities are uneven distribution of inspired air, expiratory airway obstruction, loss of alveolar capillary surface available for diffusion, reduction in the vascular bed, and, eventually, pulmonary hypertension and cor pulmonale. For the purpose of this paper emphysema is classified as localized or generalized. The localized type of emphysema consists of one or more greatly enlarged alveoli with the rest of the lung normal. This probably is a congenital abnormality of one part of the lung. When cystic areas interfere with function by compressing normal lung tissue, they can be successfully removed. The generalized disease can be of unknown cause, or it can result from such disorders as bronchial asthma, bronchiectasis, tuberculosis, silicosis, and other types of chronic lung disease. Most of this discussion concerns the generalized form of the disease.

In the treatment of the patient with emphysema it is extremely important to establish the etiology of the emphysema. If it is secondary to bronchial asthma the treatment is primarily the treatment of bronchial asthma. Many physicians fail to make a clear distinction between bronchial asthma with emphysema and emphysema with chronic bronchitis. The disease in the patient with bronchial asthma and emphysema usually starts with attacks of paroxysmal dyspnea, frequently at night. The patient with primary emphysema early in his ill-

Read before the Clinical Meeting of the American Medical Association, Minneapolis, Dec. 5, 1958.

ness has dyspnea only with exertion, so his sleep is not interrupted. The patient with bronchial asthma and emphysema may have rhinitis and nasal polyps, sinusitis, and eosinophilia. The patient with emphysema and chronic bronchitis usually does not. The chest roentgenogram in both is similar, showing hyperaeration. Pulmonary function tests may not make a distinction between the two disorders; the patient with primary asthma and secondary emphysema may show improvement in vital capacity, maximal breathing capacity, and maximal flow rates after the administration of epinephrine (Adrenalin), whereas the patient with primary emphysema has a minimal or slight response. Bates [1] has reported good results in making the differentiation on the basis of diffusion, which should be normal in patients with bronchial asthma and reduced in patients with emphysema. When the asthmatic patient develops secondary emphysema, however, this test loses its value in distinguishing between these two disorders. The patient with bronchial asthma responds well to steroid therapy, whereas the patient with primary emphysema responds poorly. We believe that good response to steroid therapy in patients with pulmonary emphysema is reported because of a poor distinction between the patient with bronchial asthma and emphysema and the patient with primary emphysema. Those with bronchial asthma almost invariably improve with steroid therapy.

Aims of Treatment

Let us direct our attention to treatment of the emphysema itself. In the patient with emphysema the primary aims of treatment are to keep the patient active, to preserve as much lung tissue as possible, and to maintain comfort. The main threat to the patient is further destruction of lung tissue by infection. Therefore, all respiratory infections should be treated vigorously for an adequate period of time. In each patient, efforts should be made to find the cause of the infection. Sputum and blood should be cultured. Antibiotic therapy must be directed toward eradicating the organism causing the disturbance. Satisfactory sensitivity tests are extremely important. While awaiting the culture report, we usually use the following plan: If the patient has fever we treat him with procaine penicillin G, 300,000 units given every 12 hours, on the theory that this may be a pneumococcus type of infection which will respond to penicillin. We assure ourselves that the patient is not sensitive to penicillin by asking him about previous reactions. If he is sensitive to penicillin, erythromycin is used as outlined below. If the patient has no fever but is coughing up purulent sputum, we usually start erythromycin therapy with a dosage of 250 to 500 mg. given four times a day. The rationale is that these infections are frequently staphylococcic in origin and may respond to this therapy. Antibiotic therapy should be given for at least 10 to 14 days if once started.

The next objective of treatment is to keep the patient active. Whenever possible we recommend that he continue his work. A job requiring extensive manual labor may be impossible. Attempts should be made to find a less taxing job. The patient should be urged to exert himself to the extent of his ability and told that shortness of breath acts as a warning sign and means the time to rest is at hand. He need not fear dyspnea, for in itself it is not harmful.

The next aim of therapy is to make the patient comfortable. One of the primary problems is to clear the tracheobronchial tree of thick, tenacious, sticky secretions. Benefit can be obtained with saturated solution of potassium iodide, given in a dose of 15 drops in a half glass of water three or four times a day. This drug seems to modify sputum, in an unknown manner, so as to make it easier for the patient to expectorate. It is the best type of cough medicine to give the patient with chronic emphysema. Cough mixtures containing codeine, morphine, or meperidine (Demerol) hydrochloride, which act by suppressing the cough mechanism, should be avoided. Meperidine, especially, dries secretions and increases the difficulty of clearing the tracheobronchial tree. Bronchodilators are of only limited value in the treatment of emphysema. The patient with emphysema has expiratory airway obstruction, but it is not usually caused by intraluminal obstruction or bronchiolar spasm but by a check-valve mechanism. Because of loss of elastic tissue, the airways are poorly supported. On forced expiration they collapse. When infection occurs, mucosal edema, congestion of blood vessels in the mucosa, and secretions within the lumen of the bronchioles obstruct the airway. Epinephrine and ephedrine constrict mucosal blood vessels and improve air flow. If bronchodilators are given, they should be given both locally and systemically. When the patient inspires, air flows to the areas in the lung with the best ventilation. Therefore, medicine given by aerosol enters the best ventilated parts of the lung and does not penetrate the poorly ventilated parts of the lung where it is needed the most. We have found that some patients benefit from epinephrine, in a 1:1,000 solution, given subcutaneously in doses of 0.3 cc. Isoproterenol, aerosolized as a liquid or powder, is sometimes helpful when spasm contributes to bronchiolar obstruction. The patient may take two or three breaths of this three or four times as needed during the day. This rarely gives relief from dyspnea because of the minor part spasm plays in the ventilatory defect of emphysema, but it has the advantage of being readily available to the patient and affording quick subjective relief.

Types of Treatment

Sedatives.—If the patient can be made to breathe comfortably, he does not need sedatives. Treatment should relieve the cause of dyspnea rather than sedate the patient in an effort to have him sleep in spite of troubled breathing. Heavy sedation is hazardous, because sedatives depress the respiratory center and the patient with emphysema, even though he has dyspnea, is hypoventilating. Avoid the use of morphine and codeine. If sedatives are needed, phenobarbital in a dose of 30 to 60 mg. or chloral hydrate in a dose of 1 to 3 Gm. will give mild sedation without respiratory center depression.

Oxygen Therapy.—Oxygen therapy should be used in the patient with emphysema who is acutely ill with a respiratory infection if hypoxemia is a significant problem. Here it is useful in tiding the patient through a critical period. When the infection is over the patient no longer needs the extra oxygen. It is useful in the late stages of the disease to make the patient more comfortable. We try to avoid long-term oxygen therapy until late in the disease. Some patients become addicted to it and have trouble getting along without it. Dangers accompany the use of oxygen therapy. Since the patient with far-advanced emphysema has pulmonary insufficiency for oxygenation and carbon dioxide elimination, his main stimulus to ventilation is from the chemoreceptors in the carotid and aortic bodies. These receptors are sensitive to a low partial pressure of oxygen in the arterial blood. When oxygen in the arterial blood is increased, the chemoreceptors no longer send messages calling for increased ventilation. Since the respiratory center in the brain is insensitive to carbon dioxide, hypoventilation may follow with further accumulation of carbon dioxide and eventual carbon dioxide narcosis. It is our policy to give patients oxygen therapy intermittently for 20 or 30 minutes each hour.

Breathing Exercises.—A number of physicians who treat patients with pulmonary emphysema have been enthusiastic about the benefits of breathing exercises. The patient needs to have a clear understanding of the pathophysiology of his disease. He may have already learned to breathe out slowly and with pursed lips. If he has been told that this type of breathing actually helps to hold his airways open during expiration, it reinforces what he has found out for himself. The success of breathing exercises depends on the enthusiasm of the physician and the attractiveness of the physiotherapist. In our experience the patients use these exercises faithfully for a while, but as time goes along they tend to abandon them.

Intermittent Positive-Pressure Breathing.—For a while it was hoped that a new gadget, the Bennett valve, was going to be the answer to the problem of emphysema. The initial enthusiasm for this device has now worn off. Although it is helpful in some cases, it is not helpful in the majority. The principle of the machine is as follows: As soon as the patient starts to breathe in, a valve opens and provides air or oxygen at a constant flow. When inspiration stops, the pressure goes on being applied until it reaches a preset point at which the valve turns off and an exhaust opens. Thus, at the end of the patient's normal breath, additional gas is forced into the lung which distends the lung. The patient with emphysema has little trouble getting air in. His main problem is blowing his air out. A disadvantage of the apparatus is that it gives no help in expiration, where the help is desperately needed. A hazard of the apparatus is that the gas goes to the best ventilated parts of the lung. If the alveolar walls in these areas are thin, there is a chance of rupture of the alveoli or even rupture of the lung, especially if the machine has been set to appreciably overdistend the lung. Fowler and coworkers [2] and Leslie and associates [3] have studied intermittent positive-pressure breathing in patients with emphysema. They found that it was an elegant way to administer bronchodilator drugs but that there was little or no benefit from the positive pressure itself.

Steroid Therapy.—Steroids are of little value in the treatment of primary emphysema. Enthusiastic reports regarding steroid therapy in patients with emphysema are the result of their use in patients with bronchial asthma and secondary emphysema. Patients with bronchial asthma respond well to steroid therapy. This reemphasizes an earlier point: it is extremely important to discover the cause of the patient's emphysema. If emphysema is secondary to another type of lung disease, the primary treatment should be aimed at the underlying lung disease.

Pneumoperitoneum.—The administration of air into the peritoneal cavity to raise the diaphragm and improve the expansion of the lung has been advocated for a number of years. The theory is that in emphysema the diaphragm becomes flat at the end of expiration instead of concave or saucer shaped. Air under the diaphragm tends to restore the normal shape to the diaphragm by providing positive pressure from below. The lungs, however, may compensate for this increased pressure from below by increasing the anteroposterior diameter at the end expiratory position so that when the patient is ready for the next breath his vital capacity is unchanged, although a greater proportion of the vital capacity comes from movement of the diaphragm than it did previously. This therapy is still used some, but there is little objective evidence to support it.

Artificial Ventilation with a Respirator.—The respirator does have a definite place in the treatment of patients with respiratory acidosis. In this situation the main problem is hypoventilation. If the patient can receive adequate ventilation to oxygenate the blood and eliminate carbon dioxide from the blood, he will be improved. We find it most useful in patients who have severe emphysema and an acute infection. One disadvantage is that many patients have great difficulty in adjusting their normal ventilation to that of the respirator. Such conflict may make the patient worse instead of better. Under these circumstances, intermittent positive-pressure breathing which is initiated by the patient's inspiratory efforts may be helpful. Another disadvantage is that adequate respirator care requires trained physicians, nurses, and attendants. This arrangement usually can be found only in a large hospital center.

Smoking.—Lowell and co-workers[4] have presented statistical evidence which suggests that smoking is a cause of pulmonary emphysema. We have seen severe emphysema in a few patients who have been nonsmokers. Although this suggestion is held valid by some, it is not established. In our patients with emphysema, we recommend that they stop smoking if possible. We do not demand that they do so. Some patients are happier if they can still smoke a few cigarettes a day, and we have been willing to make this compromise.

Surgery.—Surgical removal of part of the lung in emphysema has been recommended. The theory is that if a portion of the lung is cystic and overdistended it compresses and prevents proper function of adjacent normal lung tissue. This has been demonstrated in patients with localized cysts of the lung. In the generalized form of the disease, however, removal of one section of the lung results in overdistention of another section and is of no benefit to the patient. In our experience this has not been a helpful procedure, and we do not recommend surgical removal of parts of the lung in the patient who has generalized emphysema.

Summary and Conclusions

It is important to differentiate primary emphysema from emphysema secondary to other types of lung disease. When emphysema is secondary to asthma or other lung disease, therapy should be directed to the primary disease. When emphysema exists as a primary disorder, the aims of therapy are to preserve lung tissue, keep the patient active, and make him comfortable.

Preservation of lung tissue is done by treating all respiratory infections vigorously. The patient with emphysema should be urged to continue work whenever possible. He may exert himself to the point of dyspnea. He can be made more comfortable by means of medication; however, care must be exercised in the selection of the proper drugs so that secretions are not dried out and the respiratory center is not depressed. There is no magic device which is the answer to the problem of pulmonary emphysema. The responsibility of the physician is to give the patient a clear understanding of his disorder and to counsel him concerning how his life can be regulated within the limitations imposed by this disease. In emphysema, as in other diseases, the patient needs a physician and not a gadget.

AGE AND TASTE SENSITIVITY.—A sipping technique was used to test 100 subjects, aged 15 to 89, for taste sensitivity to substances of a sweet, sour, salty, and bitter nature. It was found that the curve of development and decline for sensitivity to each of the 4 taste primaries was essentially the same. All curves showed a noticeable decline after the late fifties. No sex differences were observed nor were there any differences in taste sensitivity between smokers and nonsmokers. . . . The decreasing sensitivity to taste with age is probably due to certain degenerative changes occurring in the taste receptors. . . . Anatomical studies indicate that such changes do occur. Allara reports that the gustatory papillae reach full development at puberty and that regressive changes set in after the age of 45. Furthermore, both Machizuki, studying the foliate papillae, and Arey, Tremain, and Monzingo the circumvallate papillae, report a decrease in number of papillae with age. In addition to a decrease in number of papillae there is also a decrease in number of taste buds. Arey and associates report that in young adults there are approximately 250 taste buds in each circumvallate papilla; over the age of 70 there are less than 100.—R. M. Cooper, I. Bilash, and J. P. Zubek, *Journal of Gerontology*, January, 1959.

RADIOACTIVE ZINC IN THE PROSTATE

SOME FACTORS INFLUENCING CONCENTRATIONS IN DOGS AND MEN

George R. Prout Jr., M.D., Michael Sierp, M.D.
and
Willet F. Whitmore Jr., M.D., New York

The concentration of zinc in the prostate gland was studied in dogs with prostatic fistulas by injecting the radioactive isotope Zn^{65} intravenously. The ability of the canine prostate to concentrate and secrete zinc was demonstrated. The amount of zinc stored in the gland decreased after orchiectomy and increased greatly after administration of testosterone. It was also found possible to study the concentration of zinc in the human prostate by the preoperative intravenous injecttion of 108 to 150μc of Zn^{65} and the subsequent examination of normal and abnormal prostatic tissue removed in such operations as radical cystectomy. The normal prostate contained more Zn^{65} than did any other normal tissues examined, and neoplastic prostatic tissue generally contained less than normal prostatic tissue or tissue manifesting benign hyperplasia.

The first measurement of zinc in the prostate by Bertrand and Vladesco [1] in 1921 resulted in subsequent experiments designed to clarify the role of this trace metal in the mammalian prostate. Mawson and Fischer [2] have shown that the prostate contains a higher concentration of zinc than do any of the other soft tissues they measured in the human. They demonstrated that concentrations of zinc in normal prostatic tissue and benign hypertrophy are about equal but that prostatic carcinoma and prostatic infection are associated with decreased concentrations of zinc. Hoare, Delory, and Penner [3] found low zinc values in benign hypertrophy and prostatitis and even lower concentrations in carcinoma. Gunn and Gould [4] have demonstrated a difference in the concentration of radioactive zinc between the lateral and dorsal prostate of the rat, also that localization of concentrations of zinc occur in these structures under various endocrine influences.

With the use of dogs prepared with prostatic fistulas, we have previously demonstrated that the intravenously injected radioactive isotope of zinc, Zn^{65}, will appear in a highly predictable manner after stimulation with pilocarpine sulfate for at least 150 days and that concentration of radioactivity was nearly always greater in the first portion of dog prostatic fluid collected.[5] Biopsy of several organs in an intact dog seven days after the injection of 100 μc of Zn^{65} revealed far more radioactivity in the prostate than in any other organ sampled. Estradiol produced a rapid drop in volume and in both concentration and total amount of radioactivity in dog prostatic fluid.[5] Daniel and co-workers [6] demonstrated that intravenously administered Zn^{65} is concentrated in the human prostate and, by radioautographic techniques, they localized the Zn^{65} to the prostatic epithelium.

Methods and Material

Prostatic fistulas were created by the technique of Huggins.[7] After recovery, prostatic stimulation was accomplished by giving 5 mg. of pilocarpine sulfate (1 mg. per milliliter) intravenously at time zero. Dog prostatic fluid (DPF) was collected in two time-determined aliquots, the volume estimated, and the fluid volumetrically transferred to 5-ml. counting vials. DPF 1 was collected from time zero to 15 minutes and DPF 2 from 15 to 30 minutes after administration of pilocarpine.

The radioactive isotope of zinc, Zn^{65}, was obtained as zinc chloride with a carrier content of less than 300 mcg. per millicurie. The isotope was administered intravenously in every instance. Radioactivity was determined in a well-type scintillation counter, usually counting 1 or 2 ml. of prostatic fluid. The radioactivity recovered in 1 ml. of prostatic fluid is expressed as a percentage of the total radioactivity administered. This value is expressed as 10^{-3} in the data and is henceforth referred to as radioactivity in dog prostatic fluid.

Tissues obtained by biopsy were placed in preweighed vials and were weighed again immediately. Each vial was then frozen until radioactivity was determined. The percentage of the injected dose in each sample was expressed as radioactivity per gram of wet tissue (10^{-3}). Acetazolamide (Diamox) was injected intravenously immediately before pilocarpine was given or as indicated. The chemical analysis of sodium, potassium, chloride, and the carbon dioxide combining power were carried out according to suitable laboratory methods as re-

ported elsewhere.[8] The hydrogen ion concentration of the prostatic fluid was estimated at 1 minute and 17 minutes after the injection of pilocarpine, with the use of pHydrion indicator paper. Crystalline preparations of testosterone and estradiol were given intramuscularly as indicated in the animal experiments. Ethinyl estradiol or chlorotrianisene (Tace) was given to men as indicated.

Experiments on Dogs

EXPERIMENT 1.—Six dogs were involved in this experiment. Dogs X22 and X227 were given, respectively, 250 and 255 µc of Zn^{65}, and biopsies were performed on the prostates at 5 and 14 days thereafter. There were higher concentrations of radioactivity in the second biopsy specimens. Dog X4 was given 100 µc of Zn^{65}, and a biopsy was performed on the prostate on the seventh day. The concentration of radioactivity was greater than in any of the specimens taken from the other dogs, except the one influenced by testosterone.

Dog X371 was given 146 µc of Zn^{65} on day zero and also started on therapy with testosterone, 10 mg. intramuscularly daily. Biopsy specimen on the fifth day showed far greater concentration of radioactivity than did the controls (dogs X22 and X227). At 14 days, exogenous testosterone administration was associated with a continued pronounced rise in concentration of radioactivity to about five times the values in the control studies.

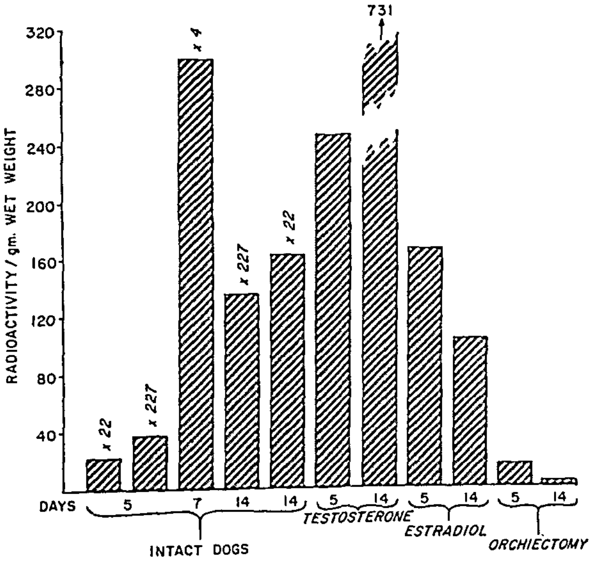

Fig. 1.—Radioactivity in canine prostate.

Dog X344 was given 146 µc of Zn^{65} on day zero and was also started on therapy with estradiol, 12.5 mcg. intramuscularly daily. Dog X262 was given 195 µc of Zn^{65} on day zero and was castrated on the same day. These dogs were also subjected to prostatic biopsy on the 5th and 14th days. Results are shown in table 1 and figure 1.

EXPERIMENT 2.—After a prostatic fistula had been constructed and a control period of 21 days completed, dog X55 received testosterone, 10 mg. daily intramuscularly. Fourteen days later bilateral orchiectomy was carried out and five days after that the dog was injected with 129 µc of Zn^{65}. Prostatic fluid was obtained at varying intervals thereafter. The results are shown in table 2 and figure 2.

Prior to the institution of exogenous testosterone, the volume of DPF produced and the concentration of radioactivity were both low in dog X55. When testosterone was given daily and the dog subsequently castrated, the volumes of DPF 1 and 2 were maintained at average levels of nearly 20 ml. and 8 ml. respectively. Radioactivity in DPF 1 and 2 reached peaks of 56 and 32 on the 7th day, and 14 and 6 on the 38th day after injection of 129 µc of Zn^{65}.

†DPF1 = fluid collected 0 to 15 minutes; and DPF2 = from 15 to 30 minutes after injection of pilocarpine.
‡ DPF1 and DPF2 combined.

EXPERIMENT 3.—Dog X75, after complete recovery from the creation of a prostatic fistula, was given 66 µc of Zn^{65}. DPF was collected at varying intervals thereafter. Details of this experiment are published elsewhere.[5] The results are shown in table 3 and figure 3.

EXPERIMENT 4.—Control studies on the ionic constituents of DPF 1 and 2 were obtained. Acetazolamide was given intravenously at time zero in amounts varying between 95 and 128 mg. per kilogram to several different dogs in which prostatic fistulas had been created. The results of this experiment are shown in table 4.

Control studies on the ionic constituents of prostatic fluid need little comment. The potassium level was always less in DPF 2 than in DPF 1, the average values being 6.6 mEq. and 3.9 mEq. per liter. Sodium was nearly always less in DPF 1 than in DPF 2, the average values being 149 mEq. and 152 mEq. per liter. The same was true of the chloride, the average values being 161 mEq. per liter for DPF 1 and 162 mEq. per liter for DPF 2. Bicarbonate ion was so low as to constitute a qualitative rather than a quantitative assay. When acetazolamide was given intravenously, no remarkable departure from the control studies could be detected.

Experiment 5.—After complete recovery from the creation of prostatic fistulas and after orchiectomy and the institution of testosterone therapy, 10 mg. intramuscularly daily, dogs X656 (weight 26 kg.) and X266 (weight 16 kg.) were given 272 μc of Zn^{65} each on day zero. Acetazolamide in 100 mg. per kilogram dose was given intravenously thrice to the former and four times to the latter. Volume and radioactivity in DPF 1 and 2 were recorded. The results are shown in table 5 and figure 4.

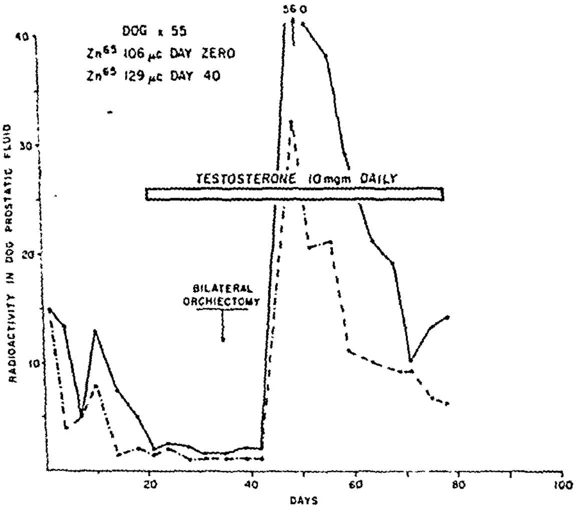

Fig. 2.—Radioactivity in prostatic fluid of dog X55. Solid line *indicates fluid collected from 0 to 15 minutes; dotted* line, from 15 to 30 minutes after injection of pilocarpine.

When acetazolamide was given to dogs who had received Zn^{65}, a peak of 71.4 in DPF 1 was seen in dog X266, but subsequent concentrations of this magnitude were not observed in this animal nor in dog X656, whose highest value of radioactivity was 21.7. No remarkable alteration in the concentration of radioactivity occurred in DPF 2 in either animal nor in the volume produced.

Estimation of the hydrogen ion concentration in experiments 4 and 5 was done more than 50 times. The pH controls revealed a usual decrease in pH from 5.5 to 5 between DPF 1 and 2. Occasionally the pH was as high as 6 or as low as 5 in DPF 2, and occasionally the decrease in pH in DPF 2 failed to occur. Administration of acetazolamide failed to alter these patterns in any way.

Report of Cases

Men with various urologic disorders were given between 108 and 150 μc of Zn^{65} intravenously, and tissue was subsequently obtained at operation by sharp dissection and never washed or immersed in fluid. The posterior lamella of the prostate was separately assayed when it could be distinctly identified. The prostatic tissue designated as "normal" was obtained *immediately after radical cystectomy* in each instance. Cowper's gland was removed in each instance during perineal dissection. Each anatomic and pathological diagnosis was substantiated histologically. Minor inflammatory responses were ignored in the pathological diagnosis. Only the major histological feature of each gland was recorded. Radioactivity in the blood is not

shown because many of the patients received transfusions in varying amounts during the surgical procedures.

Case 6.—A 60-year-old man had undergone an abdominal-perineal resection for adenocarcinoma of the rectum 20 years prior to admission for progressing signs of bladder neck obstruction. A transurethral resection was carried out and adenocarcinoma was diagnosed histologically. Two days after the administration of Zn^{65}, a radical cystectomy was carried out. The prostate was small and seemed fibrotic. A biopsy was taken of the more centrally placed portion of the prostate for the determination of radioactivity. Aside from scant inflammatory response, adenocarcinoma was again noted.

Case 7.—A healthy, sexually active, asymptomatic, 62-year-old man was told during a routine physical examination that he had a nodule in his prostate. The nodular area was confined to the capsule of the right lobe and measured about 10 mm. in greatest diameter. Two and a half days after the injection of Zn^{65}, perineal exploration and biopsy of this nodule and the opposite prostatic lobe were performed and specimens submitted for histological examination and radioactivity assay. Carcinoma was present in the nodule only.

Case 9.—An 81-year-old male had undergone three transurethral resections for an infiltrating carcinoma of the bladder and had also had partial transurethral resection of the prostate prior to radical cystectomy. He was in good health aside from cardiovascular disease. The prostate was enlarged with a firm nodule on its posterior surface that was suggestive of primary carcinoma. Zn^{65} was given a day and a half before operation. A portion of the posterior lamella of the prostate stripped readily from the radical cystectomy specimen, was separately excised, and the radioactivity determined. A deeper section of the prostate was also excised and the radioactivity determined. Histological sections of the prostate revealed adenocarcinoma in addition to some inflammatory response.

† These figures represent an average of not less than 10 determinations in each category.

‡ DPF1 = fluid collected from 0 to 15 minutes; DPF2 = from 15 to 30 minutes after injection of pilocarpine.

Case 12.—A 70-year-old man had been treated by transurethral resection for sarcoma of the prostate. The sarcoma could be felt at the base of the right lobe extending into the region of the right seminal vesicle. Four days after the injection of Zn^{65}, a radical cystectomy was performed and sections from the tumor, the uninvolved posterior lamella, and the more centrally placed prostatic tissue were examined for radioactivity.

Case 17.—A 70-year-old man had minimal urinary symptoms and was in good general condition. A firm, 12-mm., nodular mass was palpable at the base of the prostate. After exposure perineally, this mass was thought to be an area of adenomatous hyperplasia with infection present. This impression was corroborated histologically. The radioactivity present in the capsule and hyperplastic prostate was determined.

Concentrations of Radioactivity in Human Tissues

In each of the three patients whose prostates were considered normal, the concentration of radioactivity was higher in the prostate than in any of the other tissues on which biopsy was performed. The values for prostatic radioactivity in these three patients ranged from 14.0 to 5.3. In the one patient in whom the radioactivity of Cowper's gland was determined, the concentration was 3.8 (table 6).

Two of the patients suffering from carcinoma of the prostate were in relapse. Orchiectomy had been done two years previously in case 15 and six months earlier in case 13. These two patients had concentrations of 4.4 and 5.6, respectively, in their prostatic tissue. Lymph nodes removed from one during celiotomy were found to have tumor tissue present, with activities of 5.7, 6.3, and 7.8 (table 7).

One man (case 14) was given chlorotrianisene for six months without benefit of histological diagnosis of cancer. The clinical diagnosis of cancer was confirmed by biopsy of his prostate six weeks after the last dose of chlorotrianisene and three days after Zn^{65} had been given. In this patient and in eight other untreated patients with carcinoma of the prostate, the radioactivity in the prostate ranged from 12.7 to 1.8, the average being 5.5. Radioactivity in the isolated case of sarcoma of the prostate was 5.6 (table 7, case 12).

In one patient (case 7) the sharply demarcated malignant area in the prostate had a concentration of 5.1, while the adjacent tissue had a concentration of 9.6. In another man (case 9) the posterior lamella, presumed free of disease, was 6.8. This sample of tissue as well as corresponding samples obtained from the prostates of two other patients (cases 12 and 13) were not examined histologically, but no doubt exists as to the over-all diagnosis in the individual prostates (table 7).

In the other genital appendages and testes on which biopsy was performed, concentration of radioactivity was always less than in the prostate, except in one man (case 5) whose epididymis had a radioactivity of 7.1 as opposed to 6.8 for prostatic radioactivity and in another man (case 10) whose testis had only slightly greater activity than the prostate. Epididymal concentrations of radioactivity ranged from 0.9 to 7.1, and testicular concentrations from 1.6 to 3.3. Radioactivity in the vas varied from levels too low to be significant to 4.2 (table 7).

Of the nine patients with benign prostatic hyperplasia, the adenomas contained concentrations of radioactivity varying from 22.1 to 3.2, while the capsular concentration varied from 8.6 to 2.1 (table 8). Three men (cases 21, 22, and 23) received estrogen therapy in association with the administration of isotope and before prostatectomy. In these three the adenomas had radioactivity varying between 7.7 and 7.0. In two the capsular concentrations of radioactivity were 8.4 and 3.6, and in one of these was seen the greatest concentration of radioactivity in the vas (6.6). Another patient received exogenous testosterone therapy and had a concentration of radioactivity of 10.6 in the adenoma and 2.1 in the capsule. The concentrations of radioactivity in the seminal vesicle of intact men not receiving hormone treatment varied from 0.7 to 4.6. In the one patient in this group in whom the radioactivity of Cowper's gland was determined, the concentration was 2.2 (table 8).

Dog Prostatic Fluid

Since it has been demonstrated that after the intravenous administration of radioactive zinc, Zn^{65}, the concentration of that isotope in dog prostatic fluid is related to time as well as to health and general condition,[9] it seems reasonable to expect a reflection of this phenomenon in the concentration of radioactive zinc in the prostate. As demonstrated, such is the case (experiment 1, table 1, fig. 1). It is probable that we have missed the actual peaks of concentrations, especially in the prostatic tissue, but from data concerning radioactivity in DPF 1 and DPF 2[5] as well as from information regarding prostatic biopsies,[9] it seems reasonable to conclude that although each animal concentrates Zn^{65} in an individual manner, most dogs probably reach a peak of concentration within two weeks. It seems unlikely that the peak of concentration of radioactivity in prostatic fluid occurs much before five days.

§ First portion lost.

Huggins and associates[10] observed that caged dogs responded to their environment by becoming azoospermic. Weight loss, shedding, and loss of appetite are other manifestations of an adverse response to caging. It is impossible to ascertain the amount of prostatic fluid such dogs might produce under natural conditions. Most impressive is the response in terms of exaggerated production of DPF to exogenous testosterone when compared to the control period in the same dog or to other dogs dependent on endogenous androgen alone. There is also a remarkable increase in the concentration and total amount of radioactive zinc produced during the period of testosterone administration as compared with the control period in the same animal (experiment 2, table 2, fig. 2). It is conceivable that the lesser volumes and radioactivity we usually collect are the result of decreased gonadotropin production, while the response to exogenous testosterone represents more nearly the normal physiological state. Leaving these considerations aside, it is clear that the presence of radioactive zinc in the prostate and dog prostatic fluid is an androgen-dependent phenomenon, be it endogenous or exogenous in origin.

It is of interest that the total amount of Zn^{65} produced in one hour reaches relatively high levels, particularly during the first two weeks after the injection of the isotope. Dog X75 has been demonstrated to produce volumes and concentrations of radioactivity in DPF 3 (prostatic fluid secreted between 30 and 60 minutes) that are usually equal or slightly lower than those found in DPF 2.[5] Since Huggins and associates [10] have shown that 95% of the volume of prostatic fluid is produced in one hour after pilocarpine injection, the amount of radioactivity produced by X75 on any of the days shown can be calculated from table 3, assuming that total radioactivity found in DPF 3 is 90% of that found in DPF 2. Though some objection may be raised, this maneuver seems reasonable in view of this animal's previous performance.[5] Hence, on the sixth day after the injection of the isotope, about 0.54% of that dose was secreted. On the 8th and 12th days 0.28 and 0.33%, respectively, of the injected isotope was produced (experiment 3, table 3, fig. 3). Unless some hormonal influence, illness, or other catastrophe should occur, the production of DPF and radioactive zinc in similar but ever decreasing amounts will continue. This dog weighed about 18 kg., and his prostate can scarcely have exceeded 10 Gm. in weight.[11] Bearing in mind the observations that the prostates of the intact control animals have maximal concentrations of radioactivity per gram of 0.039% on the 5th day and 0.152% on the 14th day (table 1, fig. 1), it seems that the prostate must be continuously replenishing itself with the isotope rather than storing a maximal concentration during the short initial period of relatively high blood and plasma concentrations. This is buttressed by the observation that X75 and all the other dogs we have studied continued to produce relatively large amounts of isotope in addition to the fact that the control animals were never subjected to the depleting effects of pilocarpine.

*All patients were in good general condition.

We are unable to explain the alterations in the concentrations of isotope in dog prostatic fluid [5] (fig. 2, 3, and 4) and in the prostate over the first two-week period of observation. It is conceivable that Zn^{65} is being incorporated into a protein complex and that this is a time-consuming process evidenced by the lag in maximal concentration in both gland and fluid. If such were the case, one would not expect the prostate to be able to produce the relatively large amounts of isotope that it does on repeated stimulation in view of the known prostatic concentration.

Orchiectomy produces a prompt, impressive decrease in the concentration of Zn^{65} in the dog prostate. Fourteen days after orchiectomy, the concentration of radioactive zinc in the canine prostate is only 3% of the lower control value (dog X22, table 1). When estradiol was given, the volume and the concentration and total amount of Zn^{65} produced were decreased.[5] The decrease in the volume of prostatic fluid produced is more readily assessed than the alteration in Zn^{65} secretion but prostatic biopsies reveal a distinct decrease in Zn^{65} concentration. The 14-day value for radioactive zinc concentration during the administration of estradiol is 78% of the lower control value and 69% of the higher (table 1). These values are appreciably higher than those obtained after orchiectomy but it is conceivable that, had we waited for a longer period of time, the radioactivity would have dropped to lower levels. It is clear that orchiectomy acts more promptly and possibly more effectively in decreasing the concentration of Zn^{65} in the prostate than does estradiol.

Since zinc is the prosthetic metal associated with carbonic anhydrase, it seemed reasonable to attempt evaluation of the role of carbonic anhydrase in producing dog prostatic fluid. Huggins [7] has described the ionic constituents of dog prostatic fluid, but to record any acute alterations controls must first be established. Even though Mawson and Fischer [12] have demonstrated that in the prostates of the rat and rabbit there is far more zinc than can be accounted for by the presence of carbonic anhydrase, we felt it worthwhile to measure the concentration of Zn^{65} in the prostatic fluid of dogs after the intravenous injection of relatively large doses of acetazolamide, a substance demonstrated to effectively inhibit carbonic anhydrase activity.[13] We also measured volume and ionic concentrations and crudely estimated the hydrogen ion concentration. Any alteration that occurred in these features seemed to fall within the range of our established norms. The bicarbonate ion may be significantly elevated, but these levels leave doubt as to technical accuracy. It seems reasonable to conclude that acetazolamide does not effectively alter the volume, pH, ionic constituents, or Zn^{65} concentration in either DPF 1 or DPF 2. We do not necessarily conclude that carbonic anhydrase plays no role in the production or constitution of dog prostatic fluid (experiments 4 and 5, tables 4 and 5, fig. 4).

Prostatic Concentrations in Men

Acetazolamide was given in doses as high as 1 Gm. daily to six men with prostatic adenocarcinoma. No objective or subjective alteration in the patients' courses could be ascertained, even in terms of hours. When Zn^{65} was injected intravenously into men with no prostatic disorder, the prostate contained significantly more isotope than the other tissues on which biopsy was performed. Intact men with carcinoma of the prostate also had a higher concentration of Zn^{65} in their respective neoplastic glands than in nearly all of the other tissues. In general, the trend of the values is lower in the neoplastic gland than in the "normal" prostates or in the adenomas of benign hyperplasia. There are five determinations below 5.0 in the carcinoma group and only one below 5.0 in the "normal" and adenomatous groups. The sum of the patients without neoplasia makes a numerical group suitable for comparison with those intact patients with carcinoma (tables 6, 7, and 8). We were able to demonstrate that one clearly neoplastic area contained less Zn^{65} than adjacent histologically normal prostatic tissue (table 7). It would be erroneous to conclude that neoplastic tissue had less Zn^{65} in it except at the time biopsy was performed were it not for data published by Mawson and Fischer[14] on untreated patients with carcinoma of the prostate and Hoare and co-workers[3] indicating that total zinc concentrations in the neoplastic gland are unquestionably lower than in the normal gland. Hence, one might reasonably suppose that the malignant gland would have less Zn^{65} at any given time after injection of the isotope than the "normal" gland.

† Carcinoma of bladder and prostate.
‡ Sarcoma of prostate.
§ Anaplastic carcinoma of prostate. Orchiectomy performed six months before administration of isotope.
‖ Chlorotrianisene therapy discontinued six weeks before biopsy.
¶ Orchiectomy two years, estrogen stopped six months prior to isotope administration.

Daniel and co-workers[6] have reported on Zn^{65} prostatic concentration in 12 patients with various diseases. They chose to report organ/blood ratios rather than percentage of injected dose of isotope. Since many of our patients received considerable volumes of blood during exenteration, and for other reasons as well, it was determined inadvisable to show organ/blood Zn^{65} ratios. Expression of the data presented by Daniel and co-workers as percentage of injected isotope reveals no remarkable departure in values from those we have presented here except for one patient with adenocarcinoma of the prostate. This man's concentration of prostatic radioactivity was 28, a figure over twice our greatest concentration in patients with this disease. Until more information is accumulated, this concentration must be viewed as a departure from the usual trend.

Orchiectomy was not associated with a dramatic decrease in Zn^{65} concentration in the neoplastic gland. For points of reference one may refer to the unaltered concentration of Zn^{65} in striated muscle (table 7). We have to date not done the obvious experiment of taking a biopsy specimen of the prostate before and after orchiectomy. The lymph nodes in which metastatic disease was present all had radioactivity comparable to that of the primary tumor. Retrospection makes obvious the need for radioactivity determinations in uninvolved nodes.

From the data regarding radioactivity in benign hyperplasia, it is suggested that the prostate capsule contains less radioactivity than the adenoma. We took biopsy specimens from these patients at intervals of one and one-half to seven days after Zn^{65} administration and can only state that during these periods more Zn^{65} was concentrated in the adenoma than in the capsule of the individual gland (table 8). When estrogen was given with, before, or after Zn^{65}, no alteration in concentration of the isotope could be detected from the control levels. The only published data on the effect of stilbestrol on zinc concentration in the human prostate are those of Hoare and associates.[3] They were able to demonstrate a slight decrease in total zinc concentration, roughly approximating our determinations utilizing Zn^{65}. Exogenous testosterone was not associated with any clear-cut alteration in isotope concentration in the single experiment reported (table 8).

Comment

It seems inappropriate to attempt direct application of canine data to human data concerning Zn^{65}. Species difference, difference in relative mammalian age, and prostatic size are obvious objections. This may be particularly true when widespread metastases from carcinoma of the prostate are present. It is conceivable that in our present state of ignorance regarding trace element physiology, we have failed to account for the dilution of the isotope that takes place as a result of the disparity in body mass between mammals, and that, in competing for zinc with other organs, the human prostate does not concentrate the isotope as the dog's does. Nevertheless, it would seem that our canine orchiectomy and testosterone responses are so unequivocal that some alteration in Zn^{65} concentration would be demonstrable in man.

The concentrations of Zn^{65} in the human epididymis, vas, and seminal vesicle are relatively low. The feature these values all seem to have in common is that they are not subject to the wide variations that the prostatic values undergo.

We recognize that the data presented here prevent dogmatic conclusions by virtue of statistical inadequacy alone, but the information thus far obtained regarding radioactive zinc in mammalian genitalia would indicate that the propensity displayed by the prostate for Zn^{65} is an androgen-controlled phenomenon that is adversely affected by orchiectomy and the administration of female hormones in the dog. Irregular, unforeseeable concentrations of the isotope have been found in the human prostate, and it would seem that neoplasms and the prostatic capsules of benign glands have lesser concentrations of Zn^{65} than the normal and the adenomatous glands.

Still unanswered is the major question regarding genital zinc. What is its function? As pointed out elsewhere, sperm are richer in zinc than any human tissue studied, yet the testis is relatively poor in this element.[5] From this observation alone, it would seem that zinc is related to spermatic physiology. It is conceivable that the prostate acts as nothing more than a purveyor and receptacle for zinc until ejaculation occurs and at this time zinc is incorporated in the sperm in a perhaps essential capacity. Certainly, under the conditions of the experiments, the unfailing appearance of Zn^{65} in prostatic fluid and the prostate suggests that prostatic fluid without zinc would no longer be prostatic fluid.

Experiments 1 and 2 are results of work by Dr. Michael Sierp and associates[9a] and will be the subject of more detailed reports.

Data on dog X4 (table 1, fig. 1) and data in table 3 and figure 3 are reproduced with permission from Prout and associates.[5]

INAPPARENT PYELONEPHRITIS—THE MISSING LINK?

Jay P. Sanford, M.D., Dallas, Texas

A significant degree of bacteriuria has been found in some cases to exist in the absence of leukocytes in the urine and also in the absence of such urologic symptoms as dysuria, frequency, and nocturia. Autopsies disclose the presence of pyelonephritis in cases where it had not been recognized ante mortem. For these reasons it is suggested that there must exist an asymptomatic stage in the history of pyelonephritis, intervening between the acute stage and the chronic end-stage. Recognition of the asymptomatic stage depends on the development of reliable and safe techniques for detecting bacteriuria. It is essential if the termination in hypertension and uremia is to be prevented.

Inapparent pyelonephritis occupies a pivotal position in the course of pyelonephritis. Both acute pyelonephritis and chronic end-stage pyelonephritis manifested by uremia and hypertension are generally recognized. The link between these apparent phases is less well appreciated. Pyelonephritis has been found in 6 to 20% of autopsies; yet the clinical diagnosis of pyelonephritis was made in only about one-fifth of these cases.[1] This discrepancy suggests a high incidence of inapparent pyelonephritis in the general population. It is the purpose of this discussion to reemphasize the inapparent phase in the natural course of pyelonephritis and to discuss the clinical recognition of inapparent active pyelonephritis. Recognition of this phase is dependent upon safe methods for detecting bacteriuria. The value of quantitative bacterial counts as an aid in the differentiation of contaminating from significant bacteria in urine cultures and the feasibility of employing "voided" urine specimens obtained from both males and females as screening cultures to facilitate the detection of inapparent pyelonephritis will be presented.

Spectrum of Pyelonephritis

The natural course of pyelonephritis is clinically apparent as a series of separate and unrelated events. The patient is seen by different specialists during each episode of infection, which tends to fragment genuine understanding of the course of renal infection. The discrepancy between the frequency of pathological evidence of active pyelonephritis and clinical evidence of acute pyelonephritis suggests that these separate episodes of acute infection may be linked via an active inapparent phase. Pyelonephritis may then be considered as a disease continuum, illustrated hypothetically in the figure.[2] There is additional clinical evidence which suggests the presence of continued active inapparent renal infection. For example, the so-called pyelitis of infancy usually has been considered as a self-limited illness. Long-term reevaluation has failed to justify this optimism (table 1).[3] A striking feature was the frequency of abnormalities, which included at least one of the following conditions: abnormality on intravenous urography, persistent pyuria, or positive urine cultures. The majority of these patients with residual abnormality were completely asymptomatic at the time of follow-up study.

An association between chronic pyelonephritis and arterial hypertension, necrotizing arteriolitis, and uremia was clearly demonstrated by Weiss and Parker.[4] While a direct causal relationship between pyelonephritis and arterial hypertension has not been unequivocally demonstrated, the association is definitely suggestive. The importance of inapparent pyelonephritis as a link between acute renal infection and end-stage pyelonephritis was suggested from the first by Weiss and Parker when they asked the following question: "Are cases of 'silent bacteriurias' benign, or can they cause subsequent hypertension or renal failure? Should they be treated as intensely as those associated with the clinical picture of pyelonephritis?"[5] This question as to the role of inapparent progressive pyelonephritis or "asymptomatic bacteriuria" in the natural history of pyelonephritis has not been clearly defined as yet.

Methods of Recognition

If one accepts the existence of an inapparent active phase as a possible link between episodes of clinically obvious acute pyelonephritis or between acute pyelonephritis and end-stage pyelonephritis, how can this inapparent active phase be detected? Is "silent" or asymptomatic bacteriuria a manifestation of active inapparent pyelonephritis? Evaluation of asymptomatic bacteriuria is dependent on methods for the differentiation of infection from contamination during collection of a urine specimen for culture. The urethra normally contains bacteria in the distal 2 to 3 cm.; hence, the most

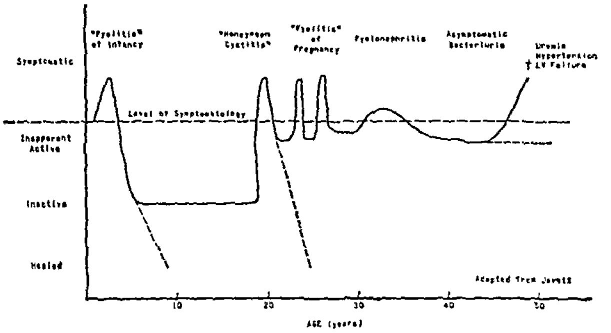
---

From the Department of Internal Medicine, University of Texas Southwestern Medical School.

Read before the Joint Meeting of the Section on Pathology and Physiology and the Section on Urology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

meticulous cleansing techniques cannot avoid contamination with organisms from the urethra either in obtaining voided or catheterized specimens.[6]

The usual method of determining the significance of any given bacterial strain has been the demonstration of its constancy in the urine in the absence of specific therapy. This method has the obvious disadvantage of requiring multiple pretherapy cultures, each taken with meticulous care. The delay this necessitates often cannot be afforded. Recently reemphasis has been placed on various techniques utilizing quantitation of the numbers of bacteria per milliliter of urine to facilitate the differentiation of "significant bacteriuria" from contaminants introduced during collection.[7] The most widely employed technique consists of diluting a fresh or freshly refrigerated urine specimen 1 to 1,000 or more times before inoculating solid culture mediums. Various dilution procedures varying from incorporating tenfold serial dilutions of urine into "pour plates" to streaking medium with a standardized loopful of urine may be utilized. These procedures enable the enumeration of the bacteria per milliliter of urine. We currently use the following technique: 0.1 ml. of urine is pipeted into a tube containing 9.9 ml. of sterile distilled water and the contents well mixed. This gives a 1:100 dilution. Then 0.1 ml. of the 1:100 dilution is added to a Petri dish and covered with approximately 10 ml. of melted cooled nutrient agar. The plate is swirled to effect mixing, allowed to solidify, incubated at 37 C overnight, and the number of bacterial colonies counted. The bacterial count represents the number of bacteria in 0.001 ml. of urine. Such techniques have been shown to be feasible in the routine general hospital laboratory.



Natural history of pyelonephritis illustrated hypothetically. Adapted from Jawetz.[2]

The consensus would place the number which distinguishes significant bacteriuria from contamination in the range of 10,000 to 100,000 bacteria per milliliter of urine. Most specimens which are contaminated during collection contain less than 1,000 bacteria per milliliter, whereas specimens obtained from patients with clinically typical acute pyelonephritis contain greater than 100,000 bacteria per milliliter. While the range between 10,000 and 100,000 bacteria per milliliter seems great, Kass[7c] found only 1% of cultures fell into this range. The relative preponderance of bacterial species isolated changes with the degree of bacteriuria. Coagulase negative staphylococci, of which the majority are nonhemolytic and nonpigmented, are commonly found in cultures with less than 1,000 bacterial colonies per milliliter. Aerobacter aerogenes and Escherichia coli occur more frequently in high concentration. These species are considered to be infrequent contaminants. It should be emphasized that the mere presence or absence of any given micro-organism is not an adequate basis for ruling it in or out as a cause of clinical urinary tract infection. A fairly good correlation exists between the concentration of bacteria and microscopic examination of stained smears of urine. Approximately 5,000 to 10,000 viable bacteria per milliliter have to be present before they can be seen on stained smears.[7b] Kass has reported that staining for bacteria is about 80% reliable.[7c]

Results

By the application of such quantitative techniques to the screening of various groups of patients, significant bacteriuria has been demonstrated with considerable frequency (table 2).[8] The variations in frequency are the result, in part, of the type of patient included in the survey. The incidence of significant bacteriuria was found to be 18% in females and 5% in males with diabetes mellitus, 11% in women at term, 23% in women with cystocoeles, and 70% in men on a urological ward.

The clinical and laboratory features observed in a group of patients with "positive cultures" were compared with those observed in a group of patients with "negative cultures" to ascertain whether or not there were clinical indications suggesting relatively asymptomatic bacteriuria.[3c] These observations were made on 100 consecutive admissions to a female general public medical ward. None of the patients had overt acute pyelonephritis. Urinary tract symptomatology consisting of minimal dysuria, frequency, and nocturia was commonly elicited from patients with positive cultures. Yet these symptoms were not present in all patients with positive cultures and were elicited from a considerable number of patients with negative cultures. Routine urinalyses in each group were quite similar. An attempt was made to separate those with negative cultures from those with positive cultures by noting the combination of clinical observations, such as

Table 1.—*Prognosis of Pyelitis in Infancy*

Author	No. of Patients	Follow-up, Yr.	Abnormalities, %
Wharton and others[3a]..........	30	10	60

* 5 deaths.

dysuria, frequency, nocturia, and the presence of leukocytes in the urine. Only 1 of 86 patients had this combination in the group with negative cultures; yet only 3 of 14 patients with positive cultures had these findings. It was found that no historical or laboratory evidence allowed separation of patients with positive cultures from those with negative cultures except the quantitative estimation of bacteriuria. Thus, asymptomatic bacteriuria is truly asymptomatic.

Comment

While the over-all incidence of asymptomatic bacteriuria in patients closely approximates the frequency with which pyelonephritis is observed at autopsy, this does not establish a causal relationship and does not answer the question: Is asymptomatic bacteriuria a manifestation of active inapparent pyelonephritis? MacDonald and co-workers [9] recently studied the relationship of bacteriuria to pathological lesions of the urinary tract in 100 unselected autopsies done on adults. The finding of true bacteriuria (defined by them as greater than 100,000 bacteria per milliliter of urine) correlated quite well with the presence of pyelonephritis, and they suggest such a relationship may also obtain during life. Kass [7c] also observed that 40% of patients with asymptomatic bacteriuria during pregnancy will develop apparent acute infection if not given antimicrobial agents. These observations certainly suggest a relationship between asymptomatic bacteriuria and inapparent active pyelonephritis.

It seems apparent that bacteriological study alone can detect these inapparent infections. Bladder catheterization is the commonly accepted technique for obtaining urine from female patients for either examination of the sediment or culture. It has been appreciated that catheterization per se includes some hazard of introducing organisms into the bladder which may be capable of producing urinary tract infections.[10] The incidence of such iatrogenic infection is not precisely known; however, it is probable in 2 to 3% of female patients after catheterization.[11] The disadvantage of this risk must be weighed against overlooking asymptomatic bacteriuria.

Collection of midstream-voided urines combined with quantitative bacterial counting has recently been compared with catheterized urine collections.[12] In a study of 100 consecutive ambulatory and nonambulatory admissions to a female general medical ward "sterile-voided" urine specimens were obtained by ward personnel, which included both graduate and student nurses.[8c] Urine obtained from 61 patients had less than 1,000 bacteria per milliliter, while that from 17 patients contained greater than 100,000 bacteria per milliliter. An "essentially negative" urine culture obtained by voided technique is obviously as meaningful as an "essentially negative" culture obtained by catheterization. Of the 17 patients with large high concentrations of bacteria on voided specimens, 13 had similar numbers of the same bacterial specie on subsequent catheterized specimens.

Kass [7c] has reported that "specimens voided into sterile containers could be obtained from females and from children and used for quantitative study." The correlation between voided specimens with bacterial counts exceeding 100,000 bacteria per milliliter and catheterized specimens is over 95%. The technique of "sterile-voided" urine cultures has been employed routinely at the Boston Lying-In Hospital for the past year and has been found to be feasible as well as satisfactory.[13] Thus, it becomes feasible to screen patients for inapparent pyelonephritis without the risk of introducing infection. However, with preliminary evidence of a significant degree of bacteriuria, either careful repetition of a "sterile-voided" urine collection or catheterization is advisable before undertaking extensive urological or bacteriological diagnostic and therapeutic regimens. Jackson and co-workers [12a] estimate that 5% of patients with low degrees of bacteriuria actually have chronic pyelonephritis. Thus, detection of the abacteriuric phase of inapparent pyelonephritis remains elusive.

Detection of the presence of inapparent pyelonephritis merely opens the door to many important questions to be answered. Are such patients predisposed to subsequent acute apparent infections? Does inapparent pyelonephritis progress to subsequent chronic pyelonephritis with hypertension and renal insufficiency? Does therapy alter the course of inapparent pyelonephritis? Most of these as yet are unanswered. In preliminary observations, Kass [7c] noted that if bacteriuria were eliminated during pregnancy, acute pyelonephritis was not encountered; whereas about 50% of patients with bacteriuria treated with placebo during pregnancy developed overt infection.

Summary

The discrepancy noted between the incidence of significant pyelonephritis demonstrable at autopsy examination and the antemortem diagnosis of pyelonephritis suggests the existence of inapparent

pyelonephritis as a phase in the natural history of pyelonephritis. The over-all incidence of "asymptomatic bacteriuria" fairly closely approximates the frequency with which pyelonephritis is observed at autopsy. Evaluation of asymptomatic bacteriuria is dependent upon bacteriological quantitative estimation of bacteriuria. Clinical history or urinalysis does not aid in detection of bacteriuria. The utilization of a quantitative culture technique enables satisfactory evaluation of voided urine cultures obtained from female patients. This facilitates detection of inapparent infection by eliminating the hazard of introducing infection. The role of inapparent pyelonephritis in the genesis of chronic pyelonephritis and the effect of therapy in altering the course of inapparent pyelonephritis is still unknown.

MUTAGENIC AGENTS.—Perhaps it will eventually be recognized as one of the most significant medical features of the early 20th century that, as a by-product of more and more powerful therapeutic procedures and the production of chemical substances outside biologic experiences, the normal protective barriers that kept mutagenic agents from the internal organs have been more and more frequently penetrated. Ionizing radiation is the most important, but . . . other agents must be at work, with increasing leukaemic incidence as the only evidence as yet of their presence. It may be only a tiny price that has to be paid for the advantages of a scientific civilization, but it is disquieting and it raises the lurking fear that anything that is increasing the incidence of leukaemia may also be breaking through the other barriers that in the past have protected the germ cells from mutagens. I think one would be wise to pay more attention to leukaemia even than its intrinsic interest and lethality demand just because of the possibility that it is the best indicator one can have of the last and greatest danger to civilization, active and avoidable genetic deterioration. . . . The exposure to physical and chemical mutagens should be reduced as much as possible. This in its turn calls for the recognition of the significant mutagenic agents in an environment always being modified by scientific and technologic development. The importance of ionizing radiation has now been recognized, and one knows how one should act in regard to it. On the chemical side a beginning has hardly been made.—M. Burnet, Leukaemia as a Problem in Preventive Medicine, *South African Practitioner*, January, 1959.

PRACTICAL VALUE OF ANALYSIS OF URINARY CALCULI

Julius H. Winer, M.D., Beverly Hills, Calif.

Classification of urinary calculi depends on comparatively simple chemical tests. Such tests yield valuable clues as to the cause of the lithiasis and the aim of treatment. The pH of urine normally fluctuates daily over a range from pH 4.5 to 7.5. Isohydruria, a narrowing of the range of diurnal fluctuation, is one of the possible causes of lithiasis and is easily remedied by diet and drugs. The list of other possible causes includes a number of conditions that are easily remedied once the cause is identified.

Urinary calculi should be analyzed after their removal or passage from the urinary tract in order to properly manage the future of the patient. Knowing the chemical composition of the calculus gives important information as to what substances are coming down in the urine and gives clues to any causes of recurrent stone formation which may be present. Although this same information may be deduced by other means, such as studies of urinary sediment, blood and urine chemistry studies, urine and blood pH records, and urologic x-ray investigation, the chemical analysis of the stone may give the first exact information and confirms the other studies.

Analysis and Chemical Composition

Analysis.—The four common crystalloid compounds in urinary stones[1] are calcium phosphate, calcium oxalate, magnesium ammonium phosphate, and uric acid; less common are calcium carbonate and cystine stones. Mixtures of these salts are common. Sulfonamide calculi are now rare. Many subtypes of common calculi due to variations in physical and chemical structure and many rare constituents are found by petrographic methods of analysis,[2] such as polarized microscopy (spectrography), x-ray crystallography, x-ray microdiffraction, microradiography, and paper chromatography. Traces of bismuth, copper, zinc, lead, silver, manganese, and fluorine have been found. As yet, these biophysical methods and findings are not practical in clinical management of the patient with urinary calculi. The presence of the common crystalloids may be determined by using eight simple spot tests (see table).

Chemical Composition.—The findings of these qualitative tests indicate the compounds which make up the stone. Uric acid and cystine stones are usually pure. Calcium is combined with phosphate, oxalate, or carbonate. A combination of magnesium and ammonium and calcium phosphate (triple phosphate) is found in infected urine. Chemical composition may direct attention to some of the exogenous and endogenous influences on the absorption, excretion, and precipitation of the crystalloids. This can be associated with knowledge of the mechanisms of stone formation.

Mechanism of Stone Formation

The urinary crystalloids are present in a supersaturated solution of electrolytes and nonelectrolytes controlled by presence of suspended colloids which also maintain a surface tension equilibrium with the urinary tract mucosa.[3]

Although there is constant crystallization and resolution of crystalloids, any disturbance of the surface tension equilibrium of the crystalloid-colloid interface or the urine-mucosa interface may cause a precipitation and conglomeration of mucopolysaccharides and mucoprotein nidus or matrix covering and preventing resolution of precipitated crystalloids. A formula of normal equilibrium and a formula of stone formation is as follows:

$$\text{Crystalloids} \longleftrightarrow \text{colloid} \longleftrightarrow \text{mucosa} \qquad \xleftrightarrow{\text{equilibrium}} \qquad \text{no stones}$$

$$\underset{\hookrightarrow}{\text{Crystalloid precipitate}} + \underset{\hookrightarrow}{\text{colloid precipitate}} \qquad \underset{\longrightarrow}{\xleftrightarrow[\text{equilibrium}]{\text{loss of}}} \qquad \text{stone formation}$$

The known exogenous and endogenous causes of stone formation affect the equilibrium at various points of the formula. They are frequently interrelated. The seven types of tendencies to calculus formation are as follows: (1) metabolic disturbances (anabolic and catabolic), uricaciduria (gout, polycythemia), oxaluria, and cystinuria; (2) endocrinopathy: hyperparathyroidism; (3) urinary obstruction (stasis): hydronephrosis; (4) infection: urea-splitting bacteria; (5) mucosal metaplasia: avitaminosis A; dietary deficiency; Randall's plaques; (6) extrinsic: dehydration; dietary excess (milk drinkers); drug excess (alkalizers, purine drugs); recumbency; chemotherapy; and (7) isohydruria[5]: loss of wide acid-alkaline tides and fixation of urinary pH. Although any one of these disturbances may be present without the formation of calculi, two or more are associated with most instances of stone formation, and the isohydruria is the condition most often found in combination with the others.

From the Department of Surgery (Urology), University of California Medical Center, Los Angeles.

Read before the Joint Meeting of the Section on Pathology and Physiology and the Section on Urology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

Isohydruria is the fixation of urinary pH within a narrow range throughout most of each 24-hour cycle instead of a normal, widely fluctuating acid-alkaline tide (pH 4.5 to pH 7.5). The pH figures as noted on nitrazine paper have been practical for clinical use. Bridges and Mattice [4] have shown that the diurnal acid-alkaline pH curve follows as regular an individual specific pattern as do human fingerprints. During stone formation, there is fixation of pH levels with characteristic but only mild fluctuations of that individual's normal curve. Reynolds [5] suggested the term "isohydruria" for this condition whether it be in the acid, alkaline, or neutral range. Isohydruria of acid type (pH 4.5 to 5.5) is associated with uric acid precipitation; alkaline isohydruria (pH 7.0 to 7.5) promotes precipitation of calcium phosphate calculi; and mildly acid to neutral fixation (pH 5.5 to 6.0) favors calcium oxalate stones.

*Spot Tests to Determine Presence of Common Crystalloids in Urinary Calculi**

Chemical	Method	Finding
1. Uric acid	Powdered stone; 1 drop 20% sodium carbonate; 2 drops uric acid reagent	Prompt deep blue color (pale blue is negative)
2. Phosphate	Powdered stone†; 4-5 drops ammonium molybdate (3.5 Gm. in 75 cc. water and 25 cc. concentrated nitric acid)	Distinct yellow precipitate (may be warmed)
3 Oxalate	a. Powdered stone; 2-3 drops 10% HCl; if no effervescence, cool and add pinch of manganese dioxide; do not mix	Tiny bubbles of gas explosively released from bottom
	b. Char small fragment on spatula and add 2 drops 10% HCl‡	Foaming effervescence
4. Carbonate	relatively large sample of powdered stone; 8-10 drops 10% HCl (save for 5, 6, 7a)	Foaming effervescence
5. Calcium	Acid extract§; 2-3 drops 20% NaOH	Fine white precipitate or film from oxalate stones; dense precipitate from phosphate stone
6. Magnesium	Acid extract; 2-3 drops of 20% NaOH; 2-3 drops "M" (ρ-nitrobenzene-azoresorcinol, 1 mg. in 100 cc. normal NaOH)	[illegible] forms)
7. Ammonium	a. Acid extract; 2-3 drops of 20% NaOH; 2-3 drops Nessler's solution	Yellowish orange precipitate
	b. powdered stone; 2-3 drops Nessler's solution	Yellowish orange precipitate
8. Cystine	a. Powdered stone; 1 drop NH_4OH; 1 drop 5% NaCN (wait 5 minutes); 2-3 drops 5% sodium nitroprusside	Beet-red color; on standing may fade to orange-red
	b. Char over flame‡	Hydrogen-sulfide odor

* Adapted from Winer and Mattice.[1]

† Performed on a micro slide, it is much easier to see the precipitate. (The other tests are best performed on an artist's spot plate on which several calculi can be analyzed simultaneously.)

‡ Simple alternate methods require heat to char the stone fragment in a platinum spatula. Technical errors can be avoided by washing surface and taking samples by scraping various layers and nucleus with a knife.

§ With use of a medicine dropper, tip plugged with a wisp of cotton, acid extract from no. 4 is taken up, cotton removed, and filtrate divided for nos. 5, 6, and 7.

Isohydruria is only a single factor influencing precipitation of the crystalloids and their colloid matrix by disturbance of equilibrium at colloid-crystalloid interface. Isohydruria may be of intrarenal origin (excretory enzymes, electrolyte excretion) or may be due to extrarenal causes, such as stasis or infection (residual urine prevents widely changing pH as a hydronephrosis and vesical neck obstruction. Infection may give a constant alkaline pH fixation). Isohydruria has been found to be temporary in some patients and permanent in others. The permanent types usually show pure calculi, whereas the temporary types often show mixed types of calculi and will on occasion have wider fluctuations of pH.

Components of Calculi

Considerable information is known regarding absorption, excretion, and precipitation of crystalloids in calculi.[6] Further investigation of the colloid factors may yield practical tests of chemical significance in the future, but only the crystalloid factors have practical clinical significance at this time.[7]

Calcium.—Although the diet contains both organic and inorganic calcium, only inorganic calcium is absorbed, probably in the upper small intestine. Calcium absorption is improved by an acid reaction and enhanced by digestion of sugars which produce intestinal acidity. Vitamin D increases calcium absorption. Dietary fat lessens calcium absorption in a high-calcium, low-phosphorus diet, but calcium absorption is increased by dietary fat with a low-calcium, high-phosphorus diet. Calcium chloride, calcium lactate, and calcium gluconate are soluble and easily absorbed, whereas the phosphate is poorly soluble and resists absorption. Protein increases calcium absorption by forming soluble calcium-amino acid complexes.

Milk and cheese are the most important calcium-containing foods. Hard water and some vegetables, especially carrots, have readily absorbable calcium, whereas spinach, rhubarb, and other high oxalate vegetables diminish calcium absorption.

Calcium is excreted into the lower small intestine and into the urine. About 150 mg. of calcium are excreted daily in the urine, but this varies widely even with a fixed diet. A positive "calcium balance" occurs when the quantity of calcium absorbed is greater than the amount excreted in the urine and bowel, occurring during growth, pregnancy, after calcium starvation, or after testosterone administration. Negative calcium balance occurs in rickets, sprue, osteomalacia, and hyperparathyroidism, during starvation, and with prolonged recumbency.

Phosphorus.—Normal urinary phosphorus occurs mostly as sodium phosphate, some as potassium phosphate, and less as calcium and magnesium phosphates; the latter salts precipitate in alkaline urine. Ingestion of alkali may cause cloudy urine (phosphaturia) by facilitating the precipitation of insoluble calcium and magnesium phosphates. The levels of urinary phosphates increase during starvation, during severe muscular exercise, and after the administration of a high-protein diet, calcium and ammonium chlorides, or parathyroid extract (Parathormone). The urinary phosphate levels diminish during pregnancy, alkalosis, renal insufficiency, and tetany and with certain bone diseases.

Calcium Phosphate Calculi.—Calcium phosphate calculi occur with excess milk intake, excess alkali intake (ulcer therapy), stasis, recumbency, avitaminosis A, hypervitaminosis D, isohydruria of a moderately alkaline type, and dehydration. In the presence of urea-splitting bacterial infection, mixed calcium phosphate and magnesium ammonium phosphate calculi occur.

Calcium phosphate calculi are associated with bone disease.[8] Hyperparathyroidism (generalized osteitis fibrosa cystica) shows hypercalciuria with precipitation of insoluble calcium phosphate in the renal pelvis, the renal parenchyma, and the other acid-excreting tissues (stomach and lungs). In osteitis deformans (Paget's disease of bone) 10% of patients have calculi. Osteoporosis with hypercalciuria occurs in the postmenopausal state, especially after surgical castration. Such hypercalciuria also is seen in senility, disuse atrophy, and decalcification of immobilization, treatment with estrogens, malnutrition, Cushing's syndrome (rare), ACTH treatment, cortisone treatment, acromegaly, multiple myeloma, hypervitaminosis C, and Fanconi syndrome (aminoaciduria).

Oxalates.—Oxalates are normally present in the urine and blood. Reliable methods of determination of blood-oxalate levels are not generally available. The normal urinary oxalate is 20 to 47 mg. in 24 hours. Urinary oxalate is supersaturated from two and one-half to three and one-half times its normal solubility at pH 5.5.[9]

Blood oxalate develops from dietary oxalate absorption, from oxalate formed by bacterial activity in the intestine, and as an intermediate product during endogenous tissue metabolism. Urinary oxalate excretion persists on an oxalate-free diet and during starvation. Spinach, rhubarb, and asparagus contain large amounts of oxalate, and many of the common fruits and vegetables have it in smaller amounts. The oxalate may be present as insoluble calcium oxalate, as soluble sodium and potassium oxalates, and, in very slight amounts, as oxalic acid. Hyperchlorhydria increases and achlorhydria decreases oxalate absorption. The soluble oxalate in the food may be absorbed; milk, with its high calcium content, prevents absorption of soluble dietary oxalates by converting them into insoluble calcium oxalate.

Tissue glycogen is a probable source of oxalic acid; oxalates are produced when carbohydrates are incompletely metabolized as in diabetes and liver disease. Oxalates may also result from the digestion of the proteins and fat. Although the oxalic acid is relatively inadequately traced in endogenous metabolism, studies show that administration of glucose, ethylene glycol, glyoxal, and glycolic acid increase oxalic acid in the urine. (Mandelic acid splits into phenol or glycocolic acid, the latter being a precursor of oxalic acid.)

Calcium oxalate calculi occur with oxaluria due to dietary excess, possible dietary deficiencies, possible metabolic errors, isohydruria at pH 5.5 to 6.0, associated with hypercalciuria, stasis, and dehydration. Oxalate metabolism and stone formation are poorly known mechanisms. Oxalate calculus formation due to acetazolamide (Diamox) has been noted, the carbonic anhydrase inhibition causing fixation of urine pH. Oxalate calculi are formed frequently with Boeck's sarcoid.

Hammarsten [10] believes that endogenous oxalate is an undesired by-product due to a metabolic disturbance resulting from magnesium deficiency. High levels of urinary magnesium are said to increase calcium oxalate solubility. In 1937, Hammarsten produced oxalate stones in rats with a low magnesium diet; the stones were larger and more numerous in the absence of vitamins and a diminution of calcium in the diet caused an increased elimination of calcium in the urine; this was more marked when the animal was deficient in vitamin D, thereby lowering absorption of calcium from the intestine. She believed that under such circumstances calcium is mobilized from the bones in excess of requirements, the excess being excreted in the urine. Stones were formed even if the diet was free of oxalate, but additional oxalate in the diet caused an increase in stone formation. The highest incidence of oxalate stones occurred with a low magnesium, high oxalate, low vitamin, acid ash diet. The resulting acid-sterile urine showed a decreased magnesium content and an increase of calcium oxalate calculi. If the diet was of alkaline ash type, calcium phosphate calculi were produced.

Uric Acid.—Exogenous uric acid is derived from dietary purines, while the endogenous portion is derived from the degradation of nucleoproteins during tissue catabolism, as well as from free mononucleotides found in muscles and glands. The liver is the probable site of destruction of 30 to 70% of the uric acid production, the remaining being excreted in the urine as free uric acid and as sodium potassium and ammonium urates. The output of urinary uric acid is 0.5 to 1.0 Gm. per 24 hours.

Uric acid calculi are usually pure (rarely urates) and are found with uricosuria, hyperuricemia, mild polycythemia (which is noted in many patients with uric acid calculi and uric acid showers), polycythemia vera, stress polycythemia,[11] lymphomas (without and especially with treatment), exogenous dietary excess, or purine drug therapy (theophylline), acid isohydruria, and hepatic disease. Relatively more bladder stones are of uric acid composition than are kidney stones. However, uric acid kidney stones may elude diagnosis and removal due to their radiotranslucency.

Comment

After a calculus is obtained from the patient, it is important to eliminate any known causes of stone formation. Chemical analysis may give information as to the specific causes of formation of each type of stone and as a guide to preventing further precipitation of this compound in the urine.

Attempts should be made to prevent excessive absorption, endogenous formation, concentrated excretion and diminished solubility. Where the etiology is unknown, the chemical composition indicates the type of isohydruria which permits each particular crystalloid to be precipitated with its associated matrix. Isohydruria may be changed by proper utilization of drug and dietary means. Intermittent alkalinization may be achieved through use of palatable alkalis or alkaline ash foods (cantaloupe is the food of greatest effect). Intermittent acidification is achieved with sodium acid phosphate, ammonium chloride, betaine hydrochloride, or acid ash foods. Cranberry juice was found to be the most potent dietary acidifier in a study of a group of paraplegics with urinary calculi. The occasional need for rapid diuresis led to use of various diuretics, but beer gave an adequate rapid diuresis in most cases.

Summary

Simple spot-test chemical analysis of urinary stones gives practical information of value for management of the patient with urinary calculi.

FIBRINOLYSIS IN UROLOGIC PATIENTS

Louis J. Lombardo Jr., M.D., Los Angeles

Severe hemorrhages after prostatic surgery may be due to a fibrin-dissolving protease found in normal prostatic tissue. The intravascular release of enzyme activators from the prostate may also explain the chronic fibrinolysis that occurs in metastatic carcinoma of the prostate. Experiments in vitro showed that the activity of these enzymes can be opposed by inhibitors. The effectiveness of two preparations of toluidine blue as inhibitors was convincingly shown by observations of plasma fibrinogen levels in 3 groups of 30 patients undergoing prostatectomy. One group received an oral preparation, the second, a parenteral preparation. The third group served for comparison. Liquefaction of extravasated blood in the prostatic fossa was found to be a characteristic phenomenon, but the question is raised whether this may be an essential part of some reparative process. Two case histories illustrate the occurrence and treatment of hemorrhage after prostatectomy.

Acquired fibrinogenopenic states occur rarely in urologic practice. It is perhaps for this reason that this hemorrhagic diathesis has not been recognized more frequently. Most physicians agree that fibrinolysis is associated with urologic cases of hypofibrinogenemia. The fibrinolytic systems, when completely understood, will probably rival in complexity the process of blood coagulation.

A proteolytic enzyme system is present in human plasma (fig. 1). Active enzyme can be prepared from the globulin fraction and an inhibitor from the albumin. The active enzyme plasmin (fibrinolysin) will act on a variety of such substrates as fibrin, fibrinogen, thrombin, prothrombin, casein, and gelatin. Since the enzyme system is not fastidious, it is frequently classified as proteolytic rather than fibrinolytic. The enzyme is derived from a precursor, plasminogen (profibrinolysin). The conversion of plasminogen to plasmin may be caused by the alarm reaction with such stress as severe physical trauma, shock, hemorrhage, burns, and fear. Plasminogen

may be activated as a result of release into the circulation of tissue activator substance and by the activity of bacteria.

A proteolytic enzyme is present in normal prostatic tissue. Tagnon and associates[1] first reported the presence of this fibrinolysin. These investigators considered this to be the fibrinolytic enzyme originally described as present in the prostatic fluid by Huggins and Vail.[2] This fibrinolysin is similar in action but probably not identical to the plasmin in normal serum.

It may be postulated that fibrinolysis associated with prostatic surgery or the chronic fibrinolysis occurring in metastatic carcinoma of the prostate may be entirely due to intravascular release of the prostatic proteolytic enzyme or due to intravascular release of enzyme activators from the prostate triggering the plasmin system. The pathogenesis in prostatic surgery may conceivably be the general alarm reaction with subsequent activation of plasminogen. It is possible that both the plasmin and prostatic systems are activated.

Studies

The fibrinolytic activity of the prostatic enzyme can be demonstrated in vitro by the fibrin plate method.[3] Purified bovine or human fibrinogen placed on Petri dishes is converted to fibrin by the addition of thrombin. Drops of test preparations are placed on the fibrin plates. Lysis produces a spreading zone of liquefaction, and the area of this, related to time, gives a quantitative measurement. Unheated fibrin plates contain plasminogen as a contaminant and thus are lysed by plasminogen-activators, such as tissue kinases. Plasminogen in such plates may be destroyed by heat denaturation.[4] The zone of liquefaction produced on a heated fibrin plate by an extract of prostatic tissue therefore represents lysis by the prostatic enzyme.

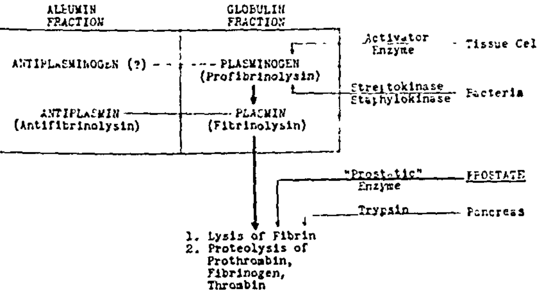

Fig. 1.—Schema of proteolytic enzymes.

Figure 2 shows a heated fibrin plate incubated with benign prostatic tissue. An extract of malignant prostatic tissue incubated on a heat-denatured fibrin plate gives a larger zone of liquefaction, indicating greater fibrinolytic activity (fig. 3).

In vitro studies were undertaken to find inhibitors of the prostatic fibrinolytic enzyme. Two inhibitors were found to be effective in fibrin plate tests, toluidine blue and Klot. Klot is a parenteral preparation of 7% *n*-butyl alcohol with 0.002% toluidine blue in isotonic sodium chloride solution. A test drop of malignant prostatic tissue incubated on a heated fibrin plate prepared with toluidine blue liquefied a small zone of fibrin (fig. 4). The small zone of dissolution indicates inhibition of lysis. A heated fibrin plate prepared with the addition of Klot was incubated with malignant prostatic tissue (fig. 5). A small zone of liquefaction indicates inhibition of lysis.

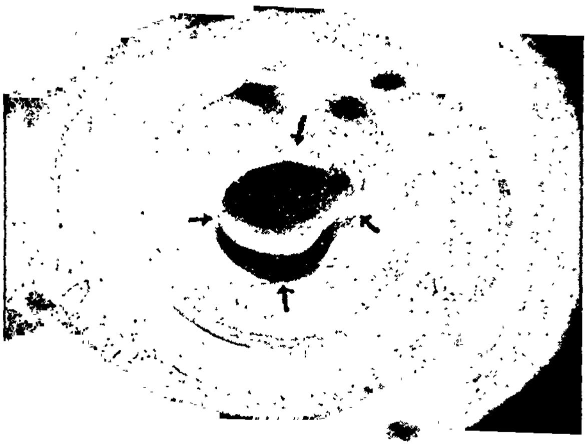

Fig. 2.—Heat-denatured fibrin plate incubated with extract of benign prostatic tissue, showing zone of lysis.

In acute cases of the prostatic fibrinolytic diathesis, the proteolytic enzyme acts to destroy fibrinogen, accelerator globulin, and prothrombin. A clinical survey was undertaken to evaluate the fibrinogen levels during transurethral prostatectomy. Plasma fibrinogen levels were determined preoperatively and one hour and four hours postoperatively in three groups of 30 patients having transurethral prostatectomies. The first group, the controls, received no special medicaments; the second group received 200 mg. of Blutene, an orally given toluidine blue preparation, 12 hours before surgery; and the third group was given Klot intravenously at the start of resection in a dosage of 1 ml. per 15 lb. of body weight. There were five cases of malignant prostatic carcinoma in each of the three groups.

In the control group the average drop in fibrinogen level from the preoperative period to four hours postoperatively was 20.3%, in the toluidine blue group 11.2%, and in the Klot group 6.3%. More striking is the observation that in 6 of the 30 subjects in the control group the fibrinogen level dropped below the low of accepted normal, 250 mg.%. In one of the six it dropped to zero, or afibrinogenemia. In the groups treated with toluidine blue and Klot, none of the fibrinogen levels postoperatively were below normal.

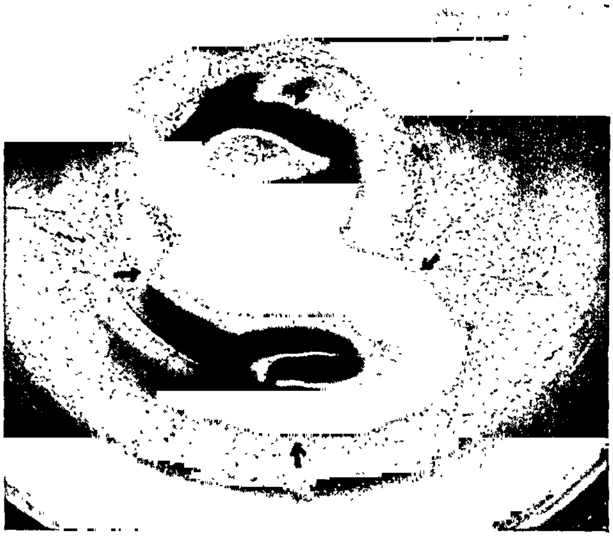

Fig. 3.—Heat-denatured fibrin plate incubated with extract of malignant prostatic tissue, showing large zone of lysis.

In recent studies, I have attempted to study the fibrinolytic activity of the prostatic fossa after prostatectomy. I thought that prostatic fibrinolysin may cause delayed or secondary hemorrhage by the premature dissolution of hemostatic blood clots before permanent repairs occur. Such hemorrhages would be postulated to occur more frequently after transurethral resection of adenocarcinoma of the prostate, since malignant prostatic tissue shows greater lytic activity. The problem of postprostatectomy hemostasis and hemorrhage is not limited to transurethral resections of carcinoma of the prostate. Conceivably, clot dissolution may occur after enucleation of a benign adenoma.

Figure 6 illustrates the method of collection of blood from the prostatic fossa after prostatectomy. A three-way urethral catheter is employed postoperatively. The catheter's irrigating lumen is plugged at the catheter tip and a hole made in the irrigating channel proximal to the retention balloon at a position corresponding to the prostatic fossa. Blood may be suctioned from the prostatic fossa postoperatively through this revised irrigating channel. There has been considerable variation in the amount of blood aspirated from the prostatic fossa. During periods of collection for blood determinations and evaluation of lytic activity, mild traction has been placed on the catheter to seat the catheter balloon against the bladder neck. This avoids contamination of collections by urine. Blood hematocrit value and hematocrit value of the collected fossa blood are determined for comparison to assure that dilution by urine of the fossa blood has not occurred.

In a group of five patients subjected to suprapubic prostatectomy, fibrinolytic activity was present in three immediately after operation. No clotting of the fossa blood was observed, and in all no fibrinogen was detectable. Lysis was demonstrated in three cases by the fibrin plate test and the lysis time of thrombin-clotted plasma. Complete lysis of blood plasma by fossa plasma in a thrombin-clotted system occurred in 24 hours. In a second group of five patients subjected to suprapubic prostatectomy and treated preoperatively with toluidine blue, no fibrinolytic activity was detected. Accurate fossa fibrinogen level determinations were not possible because of blood clots in the samples. Fibrinolytic activity was not present in the general circulation of these cases.

With present knowledge it is difficult to assess whether this fibrinolytic activity localized to the prostatic fossa is of physiological or pathological significance. Liquefaction of clotted blood is known to occur early in closed spaces, such as hematoceles and hemothorax. Alteration of this possibly physiological proteolytic activity in the prostatic fossa may be detrimental to normal healing.

Report of Cases

The cases of acute fibrinolysis observed on the urologic service have occurred mainly during or after transurethral resection. Fibrinolysis has been observed in resections of benign and malignant prostates. This hemorrhagic diathesis has occurred in resections of unsuspected malignant prostates, known malignant prostates without previous hormonal therapy, and known malignant prostates

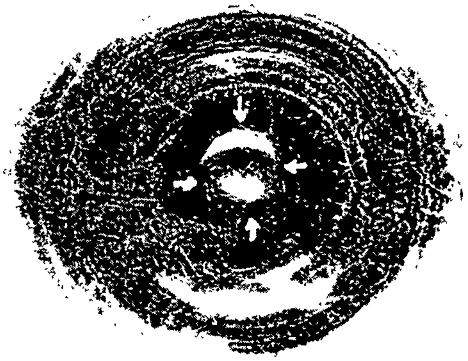

Fig. 4.—Heat-denatured fibrin plate prepared with toluidine blue and incubated with malignant prostatic tissue, showing inhibition of lysis.

during adequate hormonal therapy. Chronic fibrinolysis or instances in which fibrinolysis proceeds slowly has been observed in disseminated prostatic and bladder carcinoma.

The following case demonstrated acute fibrinolysis after transurethral resection of malignant prostatic carcinoma while the patient was on hormonal therapy.

Case 1.—A 76-year-old man entered the hospital because of symptoms of urinary obstruction. Twelve years preceding admission a transurethral resection of the prostate was performed for obstructing adenocarcinoma of the prostate. The patient had been maintained on estrogen therapy for the 12 years. On examination the testicles were atrophic and the prostate small and clinically malignant. An x-ray survey of the bones revealed no evidence of metastases. The serum acid phosphatase level was 6.7 King-Armstrong units. A transurethral resection of the prostate was performed without incident. Four hours postoperatively profuse bleeding from the catheter, without clots, was noted. The blood-clotting time was five minutes, and complete lysis of the clot occurred in one hour. The plasma fibrinogen level was 39 mg.%. Five units of whole blood, 5 Gm. of fibrinogen, and 20 ml. of Klot were administered. Nine hours postoperatively the hemorrhage was controlled. The next day, the blood-clotting time was 5 minutes and there was no clot lysis in 24 hours. The patient was discharged on the sixth postoperative day.

The following patient showed acute fibrinolysis after transurethral resection of benign prostatic tissue.

Case 2.—A 56-year-old man was admitted to the hospital because of symptoms of urinary obstruction. Early during transurethral resection of the prostate the capsule was perforated. The surgeon completed the resection while bleeding continued from the site of perforation. A total of 19 Gm. of benign prostatic tissue was resected. The estimated blood loss at surgery was 800 ml. The patient returned to his room with a stable blood pressure with whole blood being given intravenously. One hour postoperatively profuse bleeding from the catheter, without clots, was noted. Subcutaneous hemorrhages developed on both upper extremities. The blood-clotting time was six minutes, and there was complete clot lysis in two hours. The plasma fibrinogen level was 100 mg.%, and the platelet count was normal. Therapy included 4 units of whole blood, 2 Gm. of fibrinogen, and 25 ml. of Klot given intravenously. Eight hours postoperatively the bleeding was controlled, the plasma fibrinogen level was 220 mg.%, and no clot lysis was observed in 24 hours.

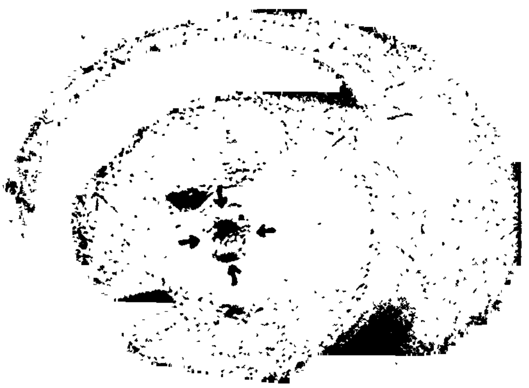

Fig. 5.—Heat-denatured fibrin plate prepared with Klot and incubated with malignant prostatic tissue, showing inhibition of lysis.

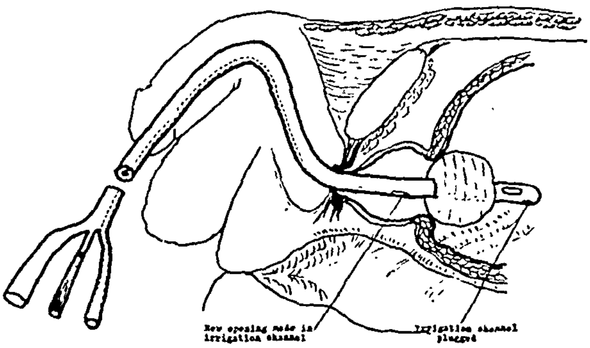

New opening made in irrigation channel

Diagnosis

The first requisite for establishing the diagnosis of fibrinolysis as a cause of abnormal bleeding is the consideration of its possible existence. Generalized ooze may be noted in the prostatic fossa during transurethral resection. I have noted the delayed occurrence of the lytic syndrome up to six hours postoperatively. Bleeding via the urethral catheter may suddenly change from pinkish or dark old blood to bright red drainage. Usually the bright red blood from the catheter is without blood clots. Sites of fresh punctures in the skin for medication bleed profusely. The skin puncture for spinal or caudal anesthesia may bleed. Subcutaneous and submucosal hemorrhages are noted.

There are many methods of studying fibrinolysis. From the point of view of the clinician, observation of the blood clotting and the future integrity of the clot is both a diagnostic test and also helpful in following the effectiveness of therapy. Venous blood is allowed to clot in a glass test tube at 37 C. The clot is observed from time to time. If lysis occurs, the red blood cells become free and sink to the bottom of the tube, leaving a top layer of serum. In severe cases, the clot may lyse very rapidly after clotting of blood or there may even be no clot formation whatever. The activity of the fibrinolytic enzyme is in direct proportion to the time required for the lysis of the clot.

It is important to remember that clot lysis may be more apparent than real in hypofibrinogenemia. Blood which has a very low concentration of fibrinogen forms a temporary solid clot which is unable to hold together the mass of red blood cells as it retracts. The small retracted mass of fibrin that ultimately remains is masked by a mass of cells, thus making it appear that liquefaction of the whole clot has occurred. Fibrinogen level and prothrombin time determinations and a platelet count are helpful in establishing an accurate diagnosis.

Treatment

In acute fibrinolysis immediate and vigorous measures must be taken. Shock may result in massive activation of fibrinolysin. With further destruction of coagulation proteins, more bleeding takes place and the shock state deepens. Death results unless such a vicious cycle is interrupted. Reference to figure 1 helps to understand the rationale of therapy. Whole blood is essential for rapid replacement and maintenance of blood volume. Whole blood acts upon the abnormal plasma proteolytic activity both directly and indirectly. The direct action is in the supplementation of the patient's plasma with the antifibrinolysin of the albumin fraction. A disadvantage of whole blood is its normal content of profibrinolysin and fibrinolysin of the globulin fraction. With more profibrinolysin available to the patient's enzyme activating system, the proteolytic activity is augmented. The indirect action of whole blood on fibrinolysis is in the supplementation of substrate in the form of fibrinogen, prothrombin, and other coagulation factors. The prevention of shock is probably the most important single indication for blood transfusions in acute fibrinolysis.

Administration of human serum albumin is a direct attack, for it is in the albumin fraction of blood that antifibrinolysin resides. Fibrinogen supplies large amounts of substrate to expend the lytic enzyme and also restores the clotting mechanism. I have alternated 1 Gm. of fibrinogen and 100 ml. of albumin every half hour until there is clinical lessening of bleeding.

Toluidine blue or Klot has been given intravenously for inhibition of circulating lysin. The dosage of toluidine blue found effective is 100 mg. and of Klot 1 ml. per 15 lb. of body weight. Toluidine blue must be diluted to 100 ml. in a vehicle such as glucose and water.

Stefanini and Gendel[5] have reported satisfactory control of the bleeding tendency of disseminated prostatic carcinoma by the administration intramuscularly of ACTH (80-120 units daily in divided doses) or cortisone (150-200 mg. daily in divided doses) until bleeding is arrested. The chronic fibrinolysis of disseminated prostatic carcinoma can often be controlled by stilbestrol therapy. As remission sets in and dissemination of the prostatic tissue is reduced, the bleeding tendency regresses and fibrinolysis disappears.

Comment

It is probable that fibrinolytic activity developing spontaneously in patients who have undergone transurethral resection is due to release into the blood stream of prostatic proteolytic enzyme. Further resection, with open venous sinuses or capsular perforation, provides possible sites for entry into the circulation of prostatic proteolytic enzymes or prostatic tissue activators to trigger the plasma enzyme system. Further evidence for this is the observation that men undergoing transurethral resection of bladder tumors maintain essentially constant plasma fibrinogen levels in the postoperative period. A possible deduction from this is that manipulation or massage of the prostate by a sheath riding over the prostate is not sufficient for intravascular release of prostatic proteolytic activators or enzymes. Further studies of localized prostatic fossa fibrinolytic activity may lead to remedies of the problem of postprostatectomy bleeding and secondary hemorrhages.

Summary

Fibrinolysis in prostatic surgery may be due to intravascular release of the prostatic proteolytic enzyme or of enzyme activators from the prostate triggering the plasmin system. Two prostatic fibrinolytic enzyme inhibitors, toluidine blue and Klot (a parenteral preparation of 7% *n*-butyl alcohol with 0.002% toluidine blue in isotonic sodium chloride solution), were found effective in in vitro and in vivo studies. Acute fibrinolysis after transurethral resection was demonstrated in two surgical patients, one with benign prostatic tissue and one with malignant prostatic carcinoma while on hormonal therapy. Observation of the blood clotting and the subsequent integrity of the clot is a diagnostic test and is also helpful in following the effectiveness of therapy. In acute fibrinolysis, immediate and vigorous measures must be taken.

1801 Wilshire Blvd. (57).

The toluidine blue (Blutene) used in this study was supplied by Abbott Laboratories, North Chicago, Ill. Klot, hemostatic injection, code 71A-47, was supplied by the Warren-Teed Products Company, Columbus, Ohio.

PLANNED DEVELOPMENT OF LATENT ANAL SPHINCTER

J. James Duffy, M.D., Los Angeles

This presentation has for its object the demonstration of a plan to accomplish the reconstruction and development of a workable anal sphincter, many years after birth, for patients born with imperforate anus and helped at the time of birth by colostomy. As the plan unfolds it will be seen to involve a composite concept of the embryology, the myoneural mechanism latent in the anal plate, reconstructive surgery, a highly disciplined regimen of muscle exercises in conjunction with counter-pressures, and finally the restoration of bowel continuity and abolition of the colostomy. The principles may be applied in other situations.

The first case of an attempt of this kind was reported in The Journal in 1951.[1] As a progress note on that case it is to be noted that since the definitive surgery in 1949, the patient has had no dilatations and no dietary restrictions and fully controls his bowel movements. He is happily married and has a family; he is fully employed and carries standard rate life insurance. In short, he leads a normal life.

The present case, however, presented a slightly different problem. As a result of the encouragement and experience gained from the first case, I believe the present plan to be an improvement.

Report of a Case

On June 18, 1951, a father brought his 12-year-old son for examination and opinion. The complaint was a permanent colostomy and foul-smelling anal sinus.

History.—The patient was born May 12, 1939, and weighed 3,856 Gm. (8.5 lb.); delivery was normal. Immediately it was noted that he had a totally imperforate anus, probably a Ladd type 3,[2] but there could be located a dimple of faint outline. Within two hours, through this dimple, a surgical opening was made and dilatation was done. In spite of strong laxatives, enemas, and repeated dilatations he remained at all times very constipated. Stricture was thought to be the problem, but by 9 years of age, when fecal impaction reached the splenic flexure, a colostomy was necessary. He was considered to possibly have a megacolon (Hirschsprung's disease).

The colostomy was of the double-barreled type. It brought new problems, although it saved the patient's life. In the first 11 years of his life he had had 11 major operations, the first series having been directed at the anal opening and the subsequent ones at the colostomy problem. Shortly after the first colostomy was established, it prolapsed several inches. This was shortened surgically. Within a few months' time the colostomy then retracted. At operation, the descending colon was fixed to the parietal peritoneum. In August, 1949, a permanent single-barreled colostomy was done. In October, the single-barreled colostomy had stenosed, and this was corrected surgically. In December, 1949, the colostomy again prolapsed and a plastic surgical procedure was done. After this the colostomy gave no further technical troubles.

Unsatisfactory attempts to correct an imperforate anus in a boy at birth were followed by progessive difficulty in defecation until, at the age of 9 years, fecal impaction reached the spenic flexure and colostomy became necessary. Subsequent examination of the remaining fistulous anal tract suggested that restoration of continence might still be possible. This was accomplished at the age of 12 by carefully planned plastic surgery in two stages. The second stage, in which the colostomy was closed, was carried out only after the patient had acquired and demonstrated satisfactory sphincteric control by carefully graduated, highly disciplined exercises, with use of a perineometer and water pressure. Observations seven years after the operation show that the patient is active in athletics and has made an excellent scholastic and social adjustment.

The fistulous anal tract meanwhile had persisted in incontinent foul-smelling discharge and soiling. From the human interest point of view it produced quite a family problem. The mother stated that the boy was totally immune to the odors not only from the fistulous drainage but from the colostomy soiling as well. Three teen-aged daughters in the family objected to the odors in their home when they brought in their friends. Beyond all this, the parents could well foresee the ostracism which would be in store for their son as he matured. The family history was negative for any developmental anomalies.

Diagnostic Survey.—Height, weight, and other body measurements and results of studies of the endocrine system were all within normal limits for a male of this age (fig. 1). On physical examination no other anomalies could be found. Results of laboratory studies of urine and blood were within normal limits. X-ray survey, including intravenous pyelograms, of heart, lungs, gallbladder, and gastrointestinal tract showed normal results except for x-rays of the colon. X-rays of the skull were normal. A scout film of the abdomen taken on June 21, 1951, showed a remnant of rectal pouch containing two large scybala, each measuring several centimeters in diameter. After this a catheter was inserted into the fistulous tract and barium introduced. At the same time a barium enema was done through the colostomy stoma. The film (fig. 2) shows the relationship of the rectal pouch and the colon. Except for considerable shortening of the descending colon, the colon appeared quite normal.

This boy had a higher than average I.Q. He did very well in school. He had no discernible conflicts.

Analysis.—After a great deal of thought and study had been applied to this boy's problem it did not appear to be hopeless. The number one problem was whether or not a workable, functioning sphincter ani muscle could be constructed and developed. He had the rectal pouch and the

---

From the Department of Surgery, Hollywood Presbyterian Hospital—Olmstead Memorial.

anal fistulous tract, totally divorced from the single-barreled permanent colostomy. This was fortunate in that it provided an isolated unit of the problem for attack, which would in no manner disturb his health or digestive tract otherwise, while the plan for construction and development of the anal sphincter would be in progress. If a fully functioning sphincter could be provided, then transplanting of the colon to the rectal pouch would be justified. If the sphincter could not be made to perform fully, then the patient would be spared any further ordeal with his colostomy or any further abdominal surgery.

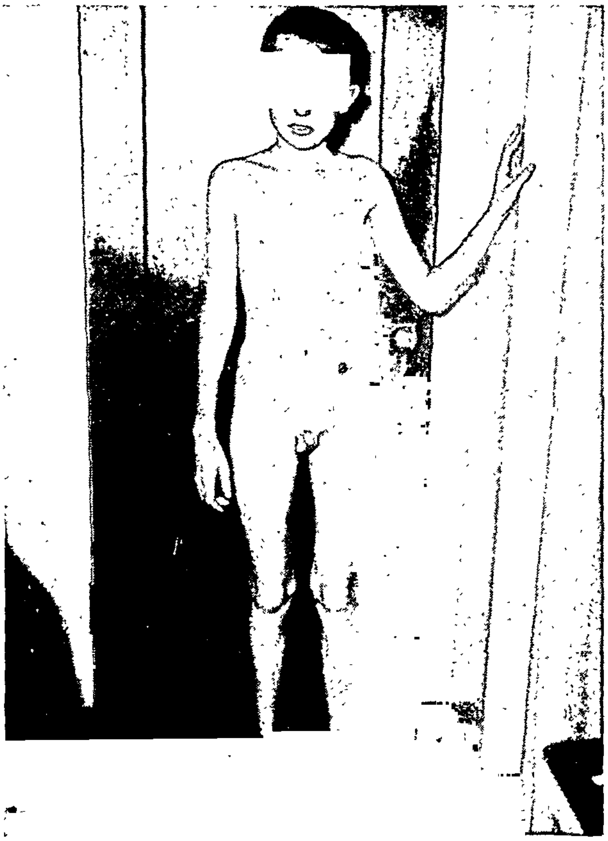

Fig. 1.—Twelve-year-old boy with permanent colostomy and anorectal fistula.

The Plan.—The projected plan was essentially simple. The first procedure would be a plastic reconstruction of the area of the anal plate. When healing had occurred, this would be followed by a regimen of carefully graduated exercises, scheduled, highly disciplined, and over a period of weeks or months. If successful, the results would not be elusive. A sphincter either works or does not work satisfactorily. If a satisfactory sphincter could be developed, then the colon would be brought down and joined with the rectal pouch and the colostomy removed.

While the plan appears simple, there are some basic factors to be considered. Each has an important bearing. Embryologically the internal and external anal sphincters are distinct entities, the external having a myoneural mechanism almost totally voluntary in control. Aside from subsequent aid from the accessory muscles of defecation, the external sphincter would be what we would have to work with. But this boy had never known a sphincter reflex, since he had always been incontinent and at 9 years of age had had the colostomy. The myoneural units of the external sphincter were surely present, even though totally undeveloped. This is readily demonstrable. As an example of undeveloped voluntary muscle, consider the three external ear muscles for moving our ears: Few people can move their ears because these muscles have not been developed. That they can be developed for entertainment purposes is readily recognized. It requires diligent exercise.

The next factor lay in the extensive scar tissue enveloping the anal sinus around which would be distributed the myoneural units of the external sphincter. This scar tissue had been built up over the 11 years from repeated attempts at repair and dilatations and the localized infections that naturally followed. By careful and diligent dissection followed by well-founded plastic surgical principles, there was the possibility of salvaging enough of the myoneural units to reconstruct the sphincter.

Assuming success to this point we come to the commonest problem of imperforate anus, common indeed to any tubal tract, namely, scar tissue contracture and stenosis. This I was prepared to deal with from past partly related experiences.[3] If the new anal opening was packed in wide dilatation, with use of a vented pack and not less than 4 cm. in diameter, the new scar tissue would be laid down in this radius within the first 24 hours. Now, if the pack were to be left in for four or five days it would fall out of its own accord, leaving a widely dilated anal opening. After healing was satisfactory, the muscle exercises, if successful, would bring the opening down to zero, since the muscle pattern is such as to close the opening; and the scar tissue, having been cast in wide dilatation, would have to follow, not lead. A technical point here is that no raw surface be permitted in the anal opening to give rise to pain and later scar tissue. With absolute hemostasis and administration of antibiotics a primary healing could be anticipated.

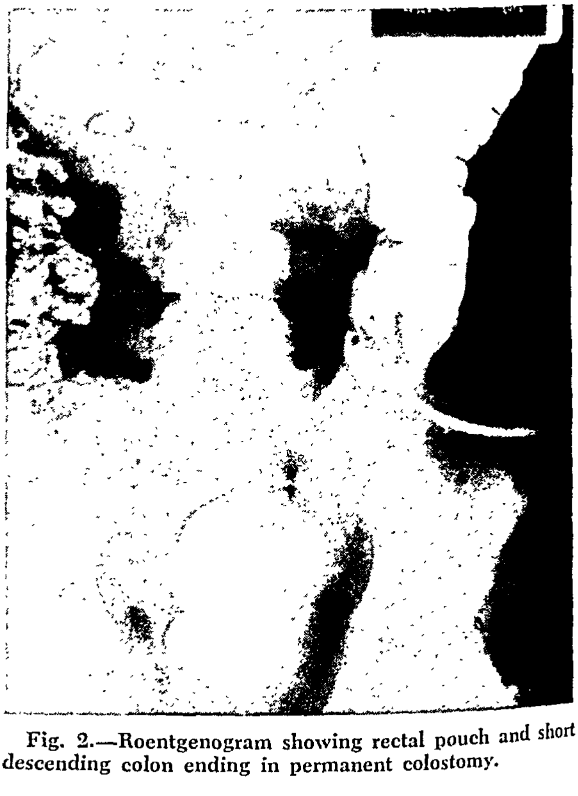

Fig. 2.—Roentgenogram showing rectal pouch and short descending colon ending in permanent colostomy.

If the surgical aspect of the sphincter problem went well, the next step would be the regimen of exercises, planned and graduated over a period of months if necessary. For the voluntary exercises of a muscle a counterpressure is necessary. For this purpose I planned to use the Kegel perineometer, for a number of reasons. The new anal orifice would be large to start with, and the compression cylinder of the perineometer is also large, having been designed for vaginal purposes. Additionally, the perineometer has a gauge which would indicate progress from day to day. If the patient succeeded with the perineometer, the next step would be a colon tube with graduated water pressure being increased as the boy made progress. If the progress with the colon tube were satisfactory, then the same routine with a catheter would be followed. Finally, if the plan were to be effective, the patient would have to be able to hold fluid in the rectal pouch for prolonged periods of time while he went about his daily routine at home and at school. If this last accomplishment could be obtained to the absolute satisfaction of the boy, his parents, and the surgeon, then the restoration of the bowel continuity would be warranted.

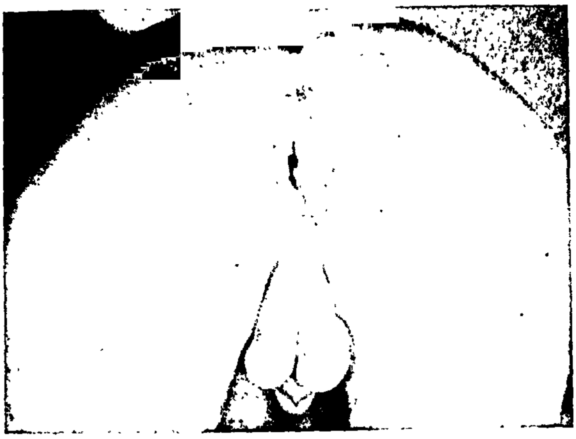

Fig. 3.—New anal opening healed in wide dilatation, before exercise regimen was begun.

This discussion and plan was presented to the boy and his parents. The parents readily accepted it. The boy wanted none of it since it meant at least one more operation and, if successful, still another operation. But he agreed to it. On July 23, 1951, I did the plastic reconstruction of the anal opening.

Surgical Procedure.—Under intratracheal anesthesia, the patient was placed in reverse Trendelenburg position on the table with the buttocks widely retracted by adhesive bands secured to the table. Beginning with the lubricated little finger, slow steady pressure was applied until the finger was fully beyond the stricture. Next the same procedure was carried out with use of the index finger and then the thumb; then the index finger of one hand and the little finger of the other hand were applied simultaneously until it was possible to insert a speculum into the opening. When the retractor was in place, the next procedure was directed at removal of the two large scybala which were known to be in the rectal pouch. It was possible to grasp the first fecal mass with a placenta forceps which served to steady the scybalum for further manipulation within the rectal pouch, since it was much too large to deliver through the opening. Thus steadied, the mass, which was very tough in consistency, was gradually divided and removed by morcellation. The same procedure was applied for the removal of the second large fecal mass, after which the rectal pouch was irrigated with sterile saline solution.

At this time careful examination of the nature of the stricture demonstrated that the anorectal mucosa came up to the inner border of the stricture in a reasonably sharp margin radially and had withstood the dilatation of the stricture without being torn. There was an extremely dense transverse scar tissue band on the border of the anus anteriorly. This appeared to present the greatest mechanical factor involved in the stricture. At this point I divided this band in the middle by an incision transverse to the band but in the longitudinal body axis. It then became apparent that dilatation was readily accomplished. This incision was extended inwardly down on to the normal mucosa and outwardly down to normal skin. With a slow tedious sharp dissection, with use of small instruments, the scar tissue was now dissected back from the center to normal skin externally. Most of the scar tissue appeared to be in the skin itself without too much invasion of the subcutaneous tissues. Dissection was carried inward to the mucosa where the scarring was minimal. In only a few points was it necessary to elevate the mucosa in order to eradicate the scar tissue.

The dissection having been completed, the anal opening was widely open. In order to gain the maximum mechanical advantage in the size of the opening, I now sutured the wound transversely to its original axis, using interrupted 000 chromic catgut suture on intestinal needles. The mucosa was likewise sutured to the skin margin with interrupted 000 atraumatic catgut suture, in those places where it had been elevated. This having been completed, it was possible to admit three fingers into the new anal opening. There were no denuded areas, and there was mucosa to skin apposition at all points. After this a large-gauge gum rubber tube was tightly wrapped with 4-in. gauze and impregnated with tetracaine (Pontocaine) hydrochloride ointment, until the diameter of the pack was approximately 4 cm. This was placed in the anorectal opening without any difficulty and secured firmly with dressings and tape. The patient lost very little blood during the operation. Postoperatively he received antibiotics. The pack came away on the fifth postoperative day. Healing was primary. Figure 3 shows the anal opening, widely dilated, after healing.

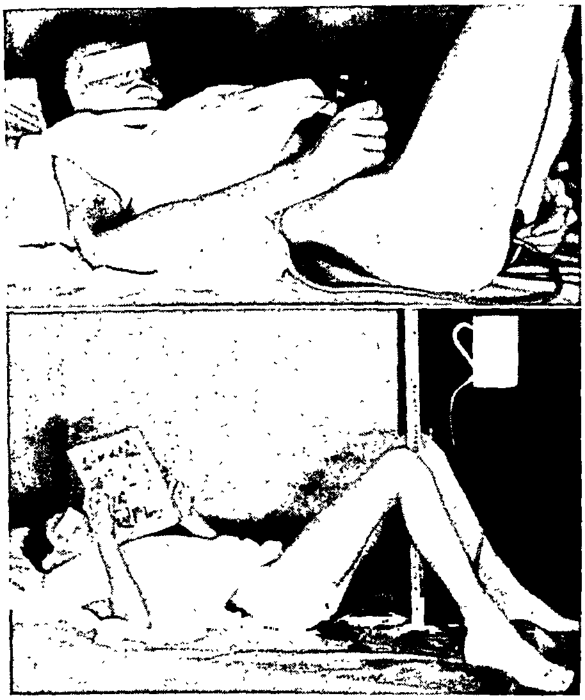

Fig. 4.—*Above,* first series of exercises begun with perineometer. *Below,* hydraulic phase of exercises with use of colon tube and enema can for pressure.

On July 31, 1951, the boy and his mother were instructed on the use of the perineometer in conjunction with a demonstration (fig. 4, *above*). It was necessary to impress on the boy that this was his project, that he would have to keep a daily log of all dates, readings attained, and time spent in exercises, and that he would have to bring this record to the office each time for inspection. This was necessary since he was prone to delegate all problems to his mother. The exercises with the perineometer consisted of 15 minutes of voluntary contractions on the pneumatic cylinder, performed three times each day while lying supine, and recording each time the height to which the gauge rose. His log records were extremely meticulous and neat.

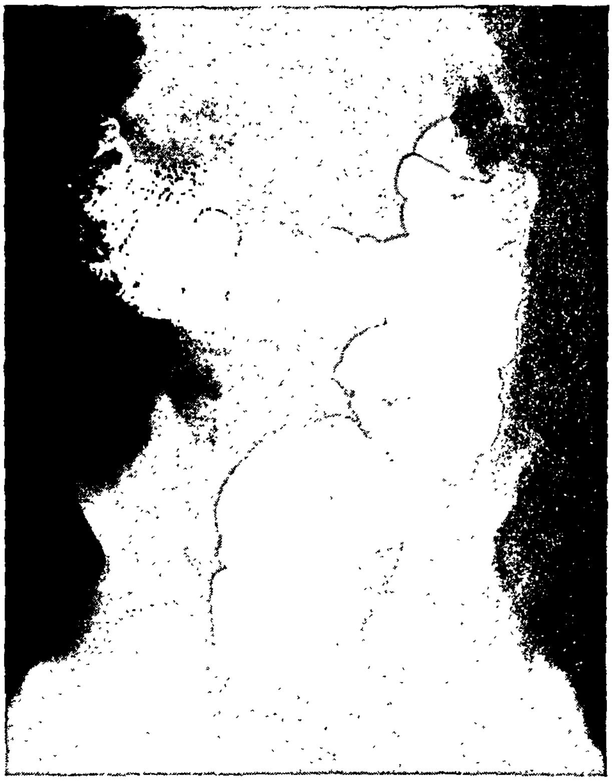

Fig. 5.—Roentgenogram of colon 10 months after restoration of intestinal continuity.

By Aug. 31, 31 days after the start of the exercises, his progress was so successful that he had exceeded the capacity of the perineometer. A satisfactory sphincteric contraction could be felt over the index finger. At this time the plan advanced to the hydraulic phase as scheduled. A colon tube was inserted into the anal opening, an enema can attached, and a yardstick used for a gauge (fig. 4, *below*). Again the program was for three 15-minute periods of exercise per day, being carried out in the bathtub at the start. By arrangement he was permitted to raise the can 2 in. if he had been successful in holding it without leakage in the previous exercise period. He was to continue his log. By Oct. 17, 1951, he had exceeded the yardstick elevation by an estimated 2 ft., for pressure. His sphincter contraction on the index finger was good. The colon tube was replaced with a catheter and the same exercise-pressure program carried out.

By Nov. 13, 1951, he could fill the rectal pouch under pressure, remove the catheter, play football for two hours, have no soiling, and then electively go to the toilet and expel it. The anal opening readily admitted the index finger without pain. He had positive satisfactory sphincteric control, in my opinion. I advised the parents that I was prepared to proceed with the abdominal phase of the plan but would prefer that they first have the boy checked by another surgeon of their choice in order to evaluate any enthusiasm which might seem warranted. This was immediately done by an officer of the U. S. Maritime Hospital. He concurred in the satisfactory status of the anal sphincter.

On Dec. 8, 1951, I did the abdominal phase of the plan. A detailed outline of the proposed surgery had been prepared for all assistants and nurses. Plan A called for the simplest procedure one could hope for, that is, mobilization of the descending colon and anastomosis of it to the rectal pouch. In view of the previous shortening and ventral fixation of the intestinal segment, plan A might not be workable. Under plan B I proposed to mobilize the splenic flexure in order to gain adequate length. Ordinarily this would not have appeared too formidable, but in view of the many previous operations and the shortening and ventral fixation, this plan might also not be feasible. Under plan C an alternative appeared, which had been noted in an upright film of the colon. This is not apparent in figure 2 because it is a prone film. The patient had an extensive ptosis of the transverse colon, and under plan C, if necessary, I planned to bring down the distal end of the transverse colon for the anastomosis.

After the abdomen was opened and the conditions estimated, they were found to be better than expected. It was possible to mobilize enough descending colon from above and enough rectal pouch from below to do an end-to-pouch anastomosis without any tension. The colostomy was removed. An appendectomy was done.

Postoperative convalescence was uneventful. On the third postoperative day the patient went to the toilet and had a bowel movement—fully controlled. He surprised us with his lack of enthusiasm over this event. On the morning of the fourth postoperative day he was in a state of great elation. He had been to the toilet and had sat for 30 minutes before allowing his bowels to move. His explanation for this happiness on this morning was that "It was the first time that I thought it would work." He left the hospital on the eighth postoperative day.

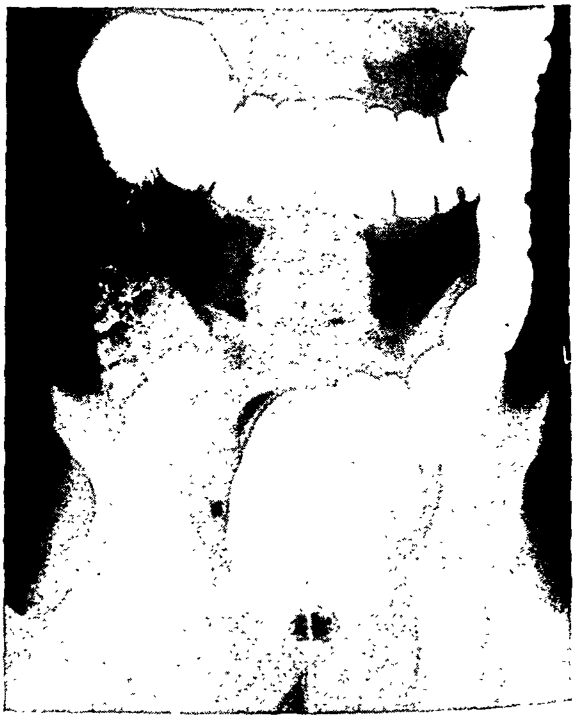

Fig. 6.—Roentgenogram of colon six and one-half years after restoration of intestinal continuity.

Results.—The patient returned to school after the Christmas holidays without loss of time. Contrary to plan he indulged himself in all of the varieties of the hamburger and

Coke diet, but without ill-effects. He has participated in athletics through high school and three years of college. *He has never had any dietary restrictions. He has never had* any dilatations of the anal opening nor need for them. His bowels move normally without any laxatives. He controls gas successfully. He can carry out the 2 oz. of castor oil regimen and drive 25 miles for a barium enema study. The first postoperative barium enema was done Oct. 11, 1952 (fig. 5). The last and only other study was done June 30, 1958 (fig. 6). The anal opening readily admits the index finger without pain. A fully satisfactory sphincteric contraction over the finger is readily demonstrated. The patient is now 6 ft. 5½ in. (197 cm.) tall and very successful in his third year of college.

Summary

A planned procedure for the problem, fortunately not common, of a young person with a colostomy and anal incontinence was carried out. It represented the combined application of sound plastic surgical principles, rehabilitation procedure for the development of the latent sphincter ani muscle, and restoration of bowel continuity and abolition of the colostomy. The theory advanced for the reconstruction of the anal sphincter in wide dilatation to avoid contractures, together with the subsequent muscle development program, may be a new approach. That it has been fully successful is encouraging. The principles can be applied in other procedures. It will be noted that this report has been delayed for seven years. This has been so elected in order that the boy reach maturity, that enough time elapse to permit proper evaluation of the results without undue enthusiasm.

BLEEDING TENDENCY IN UREMIA

Joseph A. O'Grady, M.D., Jackson, Miss.

Clues as to the reason for hemorrhagic phenomena among uremic patients were sought in a study of 65 men whose blood urea nitrogen levels were either above 24 mg. per 100 ml. or fluctuating about uremic levels. In 49 of the patients the blood urea nitrogen level was over 50 mg. per 100 ml. A series of tests was done, including the clotting time in glass, clotting time in silicone-treated glassware, one-stage prothrombin time, prothrombin consumption, platelet count, and, in some cases, thromboplastin generation, clot retraction, and capillary fragility. No impairment of clot retraction could be demonstrated in any of the patients, and no single test gave consistently abnormal results in these patients. There was, however, a rough correlation in that more of the tests gave abnormal results at the higher levels of uremia.

That uremia is associated with bleeding has been known since the turn of the century.[1] Mason[2] has reported that bleeding from the mucous membranes of the gastrointestinal tract occurs in 21.1% of the cases. Despite this knowledge, however, the mechanism of such bleeding is not known. Recently there have appeared in the literature several articles[3] which deal with this aspect of this perplexing problem. These articles have been inconclusive in their results. In few of them have serial determinations been done on a series of patients.

Since patients in a Veterans Administration hospital tend to be rehospitalized in the same hospital, it was decided to check the coagulation mechanism on any patient with a blood urea nitrogen level of more than 30 mg. per 100 ml., expecting that in this way more than one determination would be done on an individual patient as the uremic process progressed. By this method of selection, single coagulograms[4] were done on 42 patients with blood urea nitrogen levels ranging from 24 to

---

From the Research Laboratory, Veterans Administration Hospital, and the Department of Medicine, University of Mississippi Medical School.

186 mg. per 100 ml. and multiple coagulograms were done on 23 patients whose blood urea nitrogen levels were changing. This change was usually a progressive increase of the blood urea nitrogen level, although in some patients the level fluctuated and in others it showed a decline. The diseases represented in the multiple determinations are given in table 1.

Methods

A series of tests (coagulogram)[4] was done, consisting of clotting time in glass, clotting time in glassware treated with an organosilicate compound (Desicote), one-stage prothrombin time, prothrombin consumption, and platelet count. In selected cases, thromboplastin generation and capillary fragility tests were done.

The clotting time was done in three 75-by-8-mm. glass tubes at room temperature, the time of clotting in the third tube being taken as the clotting time. The same method was used in determining the clotting time in siliconized, treated glassware. Times up to 15 minutes were considered normal in glass, and times up to 55 minutes were considered normal in siliconized glassware.

TABLE 1.—*Disease Entities in Patients Given Multiple Coagulograms*

Disease	No. of Patients	No. with Clinical Bleeding
Arteriolar nephrosclerosis	6	2
Chronic pyelonephritis	3	0
Chronic glomerulonephritis	3	2
Chronic renal disease and cirrhosis of liver	2	1
Hydronephrosis and pyelonephritis	1	0
Adenocarcinoma of pancreas with acute pancreatitis and lower nephron nephrosis	1	0
Intercapillary glomerulosclerosis (Wilson-Kimmelstiel syndrome)	1	1
Diffuse hemorrhagic pericarditis of unknown etiology	1	1
Hemorrhage, shock, and oliguria after prostatectomy	2	2*
Nephrosclerosis and cortical necrosis	1	0

*Fibrinolysin found not to be a factor.

Prothrombin consumption was determined according to the method of Sussman and associates.[5] Commercially prepared fibrinogen was used. A time of less than 25 seconds was considered abnormal.

The one-stage prothrombin time was determined according to the method of Quick,[6] with use of thromboplastin prepared from human brain during the early part of the study and, later, commercially prepared rabbit brain. A control was recorded with each determination and the patient's value checked against it. The thromboplastin was prepared to give a normal value in the 14-to-15-second range.

The platelet count was done with a counting chamber, with use of both sides of the chamber and a calibrated red blood cell pipet. The diluting fluid used was a 1% solution of edathamil disodium (Sequestrene), colored with a few crystals of cresyl blue. Normal values were between 200,000 and 400,000 per cubic millimeter. The specimens were collected from siliconized glassware, and the value obtained by the direct count was checked against a coverslip preparation made from the same specimen and stained with Wright's stain.

The prothrombin consumption index was obtained by dividing the observed one-stage prothrombin time by the observed prothrombin consumption time. Since the same batch of thromboplastin was used in both determinations, variations due to the thromboplastin should be equalized. The normal range obtained on patients without known coagulation defects or bleeding tendencies was found to be 30-55%. This index was based on a formula devised by Merskey.[7] Abnormal consumption is denoted by values greater than 55%.

The thromboplastin generation test was done according to the method of Biggs and Douglas,[8] as modified by Bell and Alton.[9] Clot retraction was done according to the method of Budtz-Olsen.[10] No impairment in clot retraction could be demonstrated in any of the patients. These results are not quoted below. In no instance was any evidence of dissolution of the clot observed.

One hundred two coagulograms were done on 65 patients, 23 of whom had more than one coagulogram done during the course of illness. Of this latter group, 17 died. The thromboplastin generation test was done on 19 occasions on 15 patients, and results were always within normal limits, as judged by a concomitant examination on a normal control subject. Forty-nine of the coagulograms were done on patients having a blood urea nitrogen level of more than 50 mg. per 100 ml.

Results

The incidence of abnormalities occurring at the different ranges of blood urea nitrogen level is summarized in table 2. Table 3 shows the changes in the various tests of the coagulogram in relation to the change in the blood urea nitrogen level in the 23 patients who had more than one coagulogram. In addition to the patients included in these tables, two patients were studied who showed increasing abnormalities as the blood urea nitrogen level increased and then returned to normal as it decreased.

Since no constant defect in the coagulogram was demonstrated as the blood urea nitrogen level increased, it was decided to analyze the results according to the number of coagulation defects found at different ranges of the blood urea nitrogen level. The results are presented in table 4.

Comment

In table 2 are presented the results of the various tests in the coagulogram in all the patients with uremia included in this study. The percentages of abnormal results seem quite high in the lower levels of blood urea nitrogen, and this is particularly true of the prothrombin times. However, an analysis of the degree of abnormality reveals that of the 12 abnormal prothrombin times encountered in patients having a blood urea nitrogen level of more than 100 mg. per 100 ml., a group in whom it would be expected that such an abnormality would be significant, the range of difference between the patients and their controls was 1.4 to 8.5 seconds, with an average of 3.3 seconds. It is doubtful that such minor prolongation of the prothrombin time would be directly responsible for the clinical bleeding observed. Moreover, some of the patients studied had evidence of liver disease which was not related to or associated with the uremic process.

*Highest level, 186 mg. %.
†Totals show which tests were most frequently abnormal in patients with uremia.

From tables 2 and 3 it appears that the coagulation measurements most affected by an increasing blood urea nitrogen level are the one-stage prothrombin time, the platelet count, the prothrombin consumption, and the prothrombin consumption index. These tables reveal that the coagulation impairment is directly related to the height of the blood urea nitrogen level.

It has been claimed that the bleeding tendency in uremia is due to increased fragility of the capillaries.[3d] During the course of this study, several tourniquet tests were done and in none of them was there a greater response than 15 to 20 petechiae per circle of 2.5-cm. diameter. In one patient no coagulation defect could be demonstrated at a time when his blood urea nitrogen level was 120 mg. per 100 ml. and again when it was 140 mg., although he was oozing blood from his mucous membranes on both occasions and the tourniquet test finding was only 2+.

Table 3.—*Changes in Individual Coagulograms in Twenty-three Patients with Uremia, as Correlated with Changes in Blood Urea Nitrogen Level*

Clotting time, glass	1	1	0	1	20
Clotting time, siliconized	5	0	1	0	17

Other investigators in the field have felt that the platelets are at fault.[11] Larrain and Adelson[3a] and Larrain and Langdell[3b] felt that an inhibitory substance might be present. In all these investigations the platelet levels have been found to be low in some of the patients, but in few of them have they been low enough to be felt responsible for the clinical evidence of bleeding. These same investigators[12] have also found that in some of their patients there is a shortening of the prothrombin consumption time,[12] prolongation of the clotting time in siliconized glassware,[13] and abnormal thromboplastin generation.[3e] Lewis and co-workers[3c] found reduced thromboplastic function of the platelets in 8 patients, reduced accelerator activity in 7, and both in 4 of 12 patients studied.

My results are much in accord with these investigations with one important exception, namely, that the thromboplastin generation results were all within normal limits. Of the 19 such examinations performed, 6 were found to be in patients with abnormal prothrombin consumption and prothrombin consumption index yet having platelet counts in excess of 150,000 per cubic millimeter. It is most unlikely that the prothrombin consumption shortening and the prothrombin consumption index increase can be assumed to be on a basis of low platelet counts in these persons. In the method used,[9] a brain extract is substituted for the patient's platelets. This extract does not have thromboplastic activity but is capable of normalizing the thrombo-

Table 4.—*Total Incidence of Abnormal Coagulograms, Correlated with Blood Urea Nitrogen Levels*

100+	102	49	48.9

plastin generation test in platelet-deficient plasma. Therefore, this finding would seem to indicate that the platelets not only are quantitatively abnormal in some instances of bleeding but also may be qualitatively abnormal, as suggested by Rath and associates.[3e]

Whatever the underlying mechanism is, it is evident that, as the uremic process progresses, the number of coagulation abnormalities increases. Whether this is due to a deterioration of one of the factors which results in defects in the others measured, or whether the bleeding tendency is due to multiple coagulation deficiencies occurring separately as a result of the generalized deterioration of the patient, cannot be stated from this study. The normal clotting time (siliconized glassware) in most of these patients would make the possibility of a circulating anticoagulant unlikely. Also, the fact that the thromboplastin generation findings were normal would seem to argue against the presence of an inhibitor unless it had a specific effect on the platelets themselves. It does seem from the study that, if the bleeding is due to one factor, it is probably due to the defective formation of thromboplastin on a basis of a qualitative defect in the platelets.

Summary

A series of tests, including clotting time, one-stage prothrombin time, prothrombin consumption, platelet count, and, in selected cases, thromboplastin generation and the Rumpel-Leede test were done on 65 males whose blood urea nitrogen levels were elevated. Twenty-three of these patients had multiple tests as the blood urea nitrogen level was changing; most of them were tested as it was increasing. It was found that there was a rough correlation between the number of abnormal results and the height of the blood urea nitrogen level, with more of the tests giving abnormal results at the higher levels. While no single test finding tended to be consistently abnormal, the platelet count, the prothrombin consumption, and the prothrombin consumption index seemed to be most regularly affected. The bleeding tendency in uremia may be due to a qualitative defect in the platelets.

INFECTION AND DIABETES.—Even a mild infection may considerably increase the severity of the diabetes and require much more insulin than is usually given. When the infection is severe, as in carbuncles, appendicitis with peritonitis, or empyema of the gallbladder, the diabetic patient may be easily pushed into acidosis or coma. Greatly increasing the amount of insulin may or may not control the acidosis or the coma, and in order to restore the patient to his pre-acidotic condition it may be necessary to operate upon him and rid him of the infection. In such an emergency, one would have to operate in the presence of uncontrolled diabetes and then try to control the acidosis in the postoperative period. Attention should also be called to the fact that, once the patient is free of the infection, his insulin requirements may rapidly diminish. The physician must be on guard for this probability in order to avoid producing insulin shock.—D. H. Wagner, M.D., The Preparation and Care of Diabetic Patients Requiring Surgery, *The Surgical Clinics of North America*, February, 1959.

SAFFLOWER OIL-PYRIDOXINE AND CORN OIL-PYRIDOXINE EMULSIONS

THEIR EFFECT ON SERUM CHOLESTEROL LEVELS IN YOUNG ADULT MALES WHEN USED AS SUPPLEMENTS TO A NORMAL DIET

Richard Perkins, M.D., Irving S. Wright, M.D.
and
Barbara W. Gatje, B.S., New York

The effects of using safflower oil and corn oil as supplements to the usual diet were studied in 22 young healthy men. Serum was obtained weekly from each subject by venipuncture, to be analyzed for total cholesterol. Determinations during an initial observation period of five weeks afforded a basis for dividing the subjects into two matched groups with equal mean serum cholesterol levels (221 mg. per 100 cc.). One group thereupon received a supplement of safflower oil for seven weeks followed by corn oil for seven weeks; the other group received corn oil for seven weeks followed by safflower oil for seven weeks. In both groups a consistent decline in the mean cholesterol levels was observed as the experiment progressed, but the changes were not convincing because of the wide individual variations and no differences between safflower and corn oil were revealed under the conditions of this experiment. Significant cholesterol-lowering effect of these two oils can be demonstrated only if they are used as replacements for, rather than additions to, some of the saturated fats in the usual diet.

When unsaturated vegetable oils are substituted for saturated animal fat in the human diet, sustained reductions in levels of serum lipids can usually be achieved.[1] It was therefore to be hoped that vegetable oils could be used as supplements to the regular diet, so that reductions in levels of total serum cholesterol and other lipids might be possible without the restrictions of a low-fat diet. Several vegetable oil emulsions have been marketed recently and have been widely used in the treatment of patients with hypercholesteremia and arteriosclerosis.

Safflower oil and corn oil are the two oils most commonly used at present. Several of the emulsions of these oils now available also contain pyridoxine, which may be involved in fat metabolism.

An earlier report [2] from this laboratory described an experiment in which a safflower oil emulsion (without pyridoxine) was administered, with placebo controls, as supplements to young male volunteers who were maintained on an otherwise normal diet. Figure 1 is reproduced to show the results of that study, in which essentially the same group of volunteers participated as were used in the present study. No demonstrable depressant effect on total serum cholesterol levels was observed, although the volunteers took 50 Gm. of the oil daily for seven weeks.

The present experiment was designed to test the effects on the serum cholesterol level in 22 young male subjects of a safflower oil emulsion with pyridoxine and of a corn oil emulsion with pyridoxine, each used as a supplement to the usual diet.

Materials and Methods

Selection of Subjects.—Twenty-two young male medical students, averaging 24 years of age (range 22 to 26) were selected to serve as paid volunteers. All but one of these had served as volunteers in the previous experiment. None had a history or clinical evidence of atherosclerosis or thyroid disease.

Control of Diet.—Questionnaires were used to establish the following average composition of the diet: total calories, 2,400 (range 1,900 to 3,100); calories derived from fat, 40% (range 32 to 45%); and total daily fat intake, 102 Gm. (range 86 to 116 Gm.). The subjects were asked to adhere as closely as possible to their usual diets throughout the experiment but were allowed to omit desserts if they found themselves gaining weight. Each subject was weighed weekly.

Experimental Design and Method.—Serum was obtained weekly by venipuncture, with the subject in the fasting state, and analyzed for total serum cholesterol level by a modification of the method of Bloor. Most determinations were made with fresh serum, although some were performed with serum which had been frozen for several days at –15 C.

There was a preliminary control period of five weeks, during which time the subjects followed their usual activities and diets. At the end of this period, the 22 subjects were matched according to nearest average serum cholesterol levels observed

that far in the experiment. Half of the volunteers were then given a safflower oil emulsion supplement and half a corn oil emulsion supplement. Because the two preparations available differed in their water content, 150 cc. daily of safflower oil and 90 cc. daily of corn oil were prescribed. However, these dosages both contained an equal amount by weight of the particular oil, approximately 45 Gm. daily.

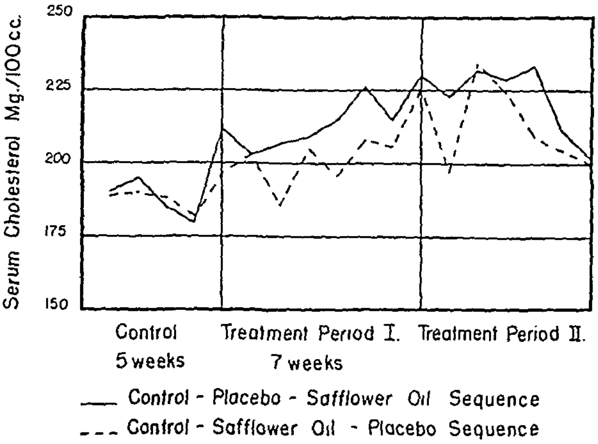

Fig. 1.—Mean total serum cholesterol levels in two groups of 12 subjects each.

The safflower oil emulsion contained linoleic acid (as safflower oil), mixed tocopherols, glycerine, emulsifying agents, polysorbate 60, sorbitan trioleate, artificial sweetener calcium cyclamate, artificial flavoring, 0.1% sodium benzoate, and 0.004% propyl gallate plus pyridoxine hydrochloride. The daily dose used contained 45 Gm. of safflower oil and 50 mg. of pyridoxine hydrochloride. The corn oil emulsion contained corn oil, polyoxyethylene sorbitan monostearate and fatty acid monostearate and fatty acid monoglyceride and diglyceride as emulsifiers, natural and artificial flavors, coloring material, 0.005% propyl gallate, and 0.1% sodium benzoate plus pyridoxine hydrochloride. The daily dose used contained 45 Gm. of corn oil and 20 mg. of pyridoxine hydrochloride.

* Final determination after 1 wk. without any supplement.

After seven weeks of therapy, the two experimental groups were reversed, so that those who had taken safflower oil then took corn oil and those who had taken corn oil then took safflower oil. After a total of 14 weeks of therapy, use of the vegetable oil supplements was discontinued and one final cholesterol level determination was performed after each subject had been without any supplement for a week.

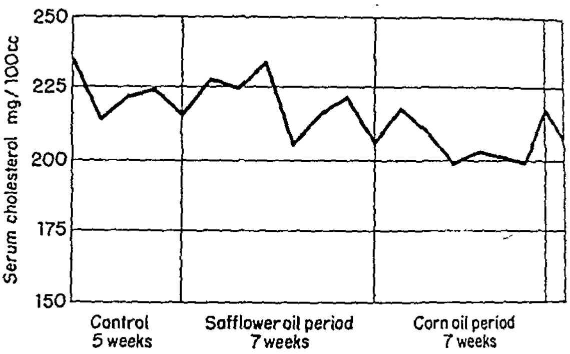

Fig. 2.—Mean total serum cholesterol levels in 11 subjects: control, safflower oil, corn oil treatment sequence.

Plasma studies in certain of the volunteers were done serially by means of the thrombelastograph, the results of which will be the subject of a separate report from this laboratory.[3]

Results

As had been the case in our previously reported study,[2] there was a considerable variation from week to week in the cholesterol levels of the individual subjects. The over-all average, however, during five weeks without therapy was 221 mg. per 100 cc. (range 125 to 311 mg.).

The addition of 150 cc. of safflower oil emulsion with pyridoxine (containing 45 Gm. of oil) to the daily diet of 11 of the subjects was followed by a slight decrease in the average serum cholesterol level (fig. 2). When, after seven weeks of this, 90 cc. of a corn oil-pyridoxine emulsion (again containing 45 Gm. daily of vegetable oil) was substituted, there continued to be a gradual downward trend in the average cholesterol level (table 1).

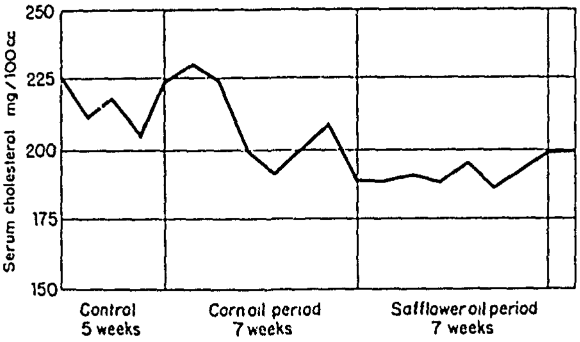

Fig. 3.—Mean total serum cholesterol levels in 11 subjects: control, corn oil, safflower oil treatment sequence.

In the other group of 11 subjects, with whom the sequence of therapy was reversed, similar results were obtained, i. e., a slight, gradual decrease in the average serum cholesterol level (fig. 3, table 2). In each group the corn oil-pyridoxine emulsion appeared to be slightly more effective.

However, the decrease in average serum cholesterol level during therapy was at no time statistically significant, whether any single week or the entire seven-week treatment period was taken as an example. That is, the decrease in average serum cholesterol level at no time was more than twice the standard deviation from the mean established during the control period.

* Final determination after 1 wk. without any supplement.

There was very little weight gain noted in these subjects. The average weight gain after 14 weeks' therapy with both vegetable oil emulsions was 0.6 kg. (1.3 lb.). In general, the oil emulsions were tolerated well, despite the large doses used. Occasional episodes of loose stools were reported.

Comment

Rivin and associates [1] have recently emphasized the fact that there may be a considerable biological fluctuation from time to time in total serum cholesterol levels of patients; they pointed out that caution is necessary in drawing inferences from a single cholesterol level determination. The results of the present study, in which wide fluctuations from week to week were observed in individual subjects' cholesterol levels (during both control and treatment periods) reinforce this view.

There is little doubt, however, from the reports of other experimenters, that the use of either corn oil or safflower oil, substituted for most of the fat in the diet, will produce a significant decrease in serum cholesterol levels. But, in this study, the results of the use of these oils as supplements to a regular diet were not significant enough to justify this as a therapeutic procedure.

Similar studies were made on a small group of patients with elevated serum cholesterol levels (more than 300 mg. per 100 cc.). These results will not be reported here in detail, but they resemble the results obtained in the young male volunteers. That is, no significant decrease in serum cholesterol level followed the use of vegetable oil supplements when the diet contained moderately high amounts of saturated fat. But, when a strict low-fat diet was used, the addition of corn oil or safflower oil supplements usually produced a greater decrease in the serum cholesterol level than had the low-fat diet alone.

The results of the experiment reported here support the idea that, when a lowered serum cholesterol level is desired, corn oil and safflower oil are best used as supplements to diets markedly reduced in their content of saturated fat. Significant results should not be expected from the use of corn oil or safflower oil, even with the addition of pyridoxine, as a supplement to the usual American diet. The slight downward trend noted in this study may have been related to the pyridoxine or other ingredients included in the emulsion, since it was not noted with safflower oil alone. Since the effect was, however, not significant statistically, this question is not clearly answered.

Summary

Twenty-two young male subjects were studied during a three-phase experiment lasting 19 weeks. After a five-week control period, they were given, in sequence for seven-week periods, a daily dietary supplement of an emulsion containing pyridoxine hydrochloride and 45 Gm. of either corn oil or safflower oil. The slight decrease observed in average serum cholesterol level was not found to be statistically significant.

This study reemphasizes the fact that, if one wishes to produce a significant lowering of the serum cholesterol level, unsaturated fats should be used only when combined with a diet which sharply limits the use of saturated fats.

525 E. 68th St. (21) (Dr. Wright).

This study was supported by grants from the Lasker, Hampil, Hyde, and Fullerton foundations and from the National Heart Institute.

The safflower oil emulsion used in this study was supplied as Linodoxine by Pfizer Laboratories Division, Chas. Pfizer & Co., Inc., New York. The corn oil emulsion was supplied as Atheroxin by Gray Pharmaceutical Co., Newton, Mass.

Mrs. Lorraine Rose and Miss Ann Florio provided technical assistance in this study.

SUBLUXATION OF THE HEAD OF THE RADIUS IN YOUNG CHILDREN

George M. Hart, M.D., Minot, N. D.

Subluxation of the radius at the elbow in children results easily from a combination of pulling and twisting forces. In the seven cases here described the most frequent age was 3 years; the youngest and oldest patients were 10 months and 4 years of age. Three fell while at play, two fell while being held by the arm, one was lifted by the arm, and one had his arm twisted by a playmate. Reduction of the dislocation required but little force and sometimes occurred spontaneously or during examination. The technique for reduction here described involves supination of the forearm while the elbow is held in the extended position and slight pressure is applied to the head of the radius by the physician's thumb. The success of the maneuver is usually attended by a slight clicking sound and immediate relief of pain.

A frequently occurring condition which responds to simple treatment is subluxation of the head of the radius in young children. The injury usually occurs between the ages of 2 and 4 years and is rare after the age of 6. The cause is forcible traction on the extended and pronated forearm and frequently is brought about when the child is lifted by the arm or stumbles while walking when held by the hand, throwing his weight on the arm. After injury there is pain in the region of the elbow, the child refuses to use the arm, and he holds the elbow slightly flexed and the forearm pronated.

The injury was described many years ago and has been known by a variety of names; among these are Malgaigne's luxation, luxation by elongation, nursemaid's elbow, and Gromeyer's injury. Griffin[1] credits Fournier[2] with the first accurate description in 1671. As described by Fournier, the injury caused incomplete dislocation of the head of the radius, relaxation of the ligaments, and downward separation or elongation of the bone. Treat-

---

From the Section of Orthopaedic Surgery, Northwest Clinic.

ment consisted of supination of the forearm with pressure on the head of the radius followed by flexion of the forearm at the elbow.

Van Arsdale,[3] in a paper read before the surgical section of the New York Academy of Medicine, noted that Hippocrates and Celsus "referred to the matter" and that histories of the subject were given by Malgaigne[4] and Streubel.[5] One hundred consecutive cases were presented in tabular form, giving the age and sex of the child and the nationality of the parents in each instance. He noted that the frequency of the condition was over 1% of surgical injuries in children. Most of his cases were in children 4 years of age or younger. One child was aged 8 years and 6 months. Reduction was accomplished by forced supination and followed by splinting to prevent recurrence.

Stone[6] in 1916 noted that Van Arsdale attributed the injury to the eccentric shape of the radial head, the epiphysis of which became pushed to one side, impinging on the ulna. In an attempt to determine the anatomic explanation of the subluxation, he carried out a number of experiments on 12 arms from material in the anatomic laboratory of the Washington University Medical School. The muscles were removed from these arms, but the ligaments were left intact. When forcible traction was applied to the first arm, the annular ligament could be seen to spring inward, but, on powerful adduction, the external lateral ligament ruptured. In the remaining 11 elbows, subluxation of the radial head was produced in 6. In each of these arms the annular ligament always slipped over the head when the hand was pronated. In the four arms the ligament tore when traction was applied with the hand supinated.

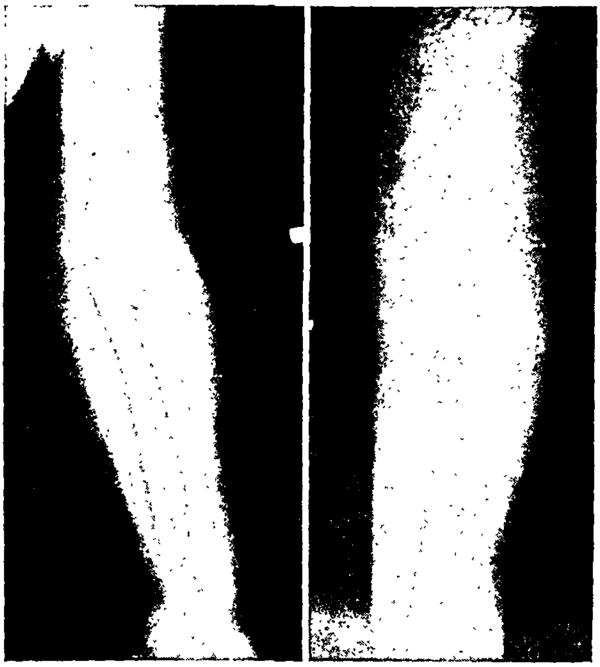
Stone also noted that, whereas standard textbooks on anatomy gave the shape of the radial head as round, measurements of 100 specimens revealed one diameter to be 1.5 mm. greater, on the average, than the other. In some bones the diameter difference was as great as 3 mm. The long diameter was always found to be in the same sagittal plane as the interior portion of the tuberosity of the radius. From these findings Stone explained the reason for subluxation occurring when the forearm was in pronation as follows: "Anteriorly, from the neck of the radius to the head, the rise is an abrupt one. Any traction with the hand supine pulls the ligament against this. Laterally and posteriorly the ascent is quite gradual, so that in pronation the ligament lies over this part and is stretched until it suddenly slips over the head."

Diagnosis

The injury occurs in a child usually between the ages of 2 and 4 years. A history of forcible traction on the extended and pronated forearm is usually described but not always obtained. After injury the child complains of pain in the region of the elbow and holds the elbow slightly flexed with the forearm pronated. The parent notes that the child refuses to use the arm and that attempts to supinate the forearm are painful. Palpation may reveal slight tenderness over the head of the radius, and occasionally the head of the radius may be somewhat more prominent than on the opposite side. Extension and flexion of the elbow are normal. Results of roentgenologic examination are usually negative, but occasionally slight separation between the head of the radius and the capitellum may be visible (see figure).

Treatment

Treatment of subluxation of the head of the radius in children is simple. The subluxation is easily reduced by manipulation as follows: The affected elbow is grasped with one hand with the thumb on the head of the radius. The forearm is held with the opposite hand at the wrist and extended. The forearm is then forcibly supinated, and at the same time slight pressure is made on the head and neck of the radius with the thumb. Upward pressure may be made on the forearm along the shaft of the radius compressing it against the capitellum of the humerus. As supination is carried out a slight click is often felt over the head of the radius, and pain and limitation of supination are relieved. Reduction is usually so easy that it may occur spontaneously or be accomplished by the parent or x-ray



Left, slight widening of joint space between proximal radius and capitellum of humerus, with elongation of radius at wrist. *Right,* normal forearm.

technician during manipulation of the arm. After reduction it is advisable to place the arm in a sling for a few days. The parents should be warned to avoid traction on the child's forearm for several weeks.

Report of Cases

CASE 1.—A 10-month-old child fell while being held by the right arm by his mother on Oct. 15, 1951. The child immediately began to cry and refused to use the arm. Examination revealed normal extension and flexion of the arm at the elbow. Supination of the forearm was limited, with pain on forcing. As supination was carried out, a mild click was palpated over the head of the radius and pain was relieved. An x-ray of the elbow was made and was normal. A long arm plaster splint holding the elbow at 90 degrees was applied and remained for four days.

CASE 2.—A 3-year-old boy was seen April 7, 1952, complaining of pain in the right wrist. Two days previously, while playing, his sister had rolled on his right arm. After the injury his parents noted that he refused to use the arm and complained of pain whenever the arm was touched. Examination revealed extension of the right forearm at the elbow to 175 degrees and flexion to 30 degrees. There was tenderness over the head of the radius. The child held the arm slightly flexed at the elbow with the forearm pronated. X-rays of the extremity were normal. A diagnosis of subluxation of the radial head was made. The dislocation was easily reduced by extension of the forearm at the elbow, followed by supination with pressure over the radial head.

CASE 3.—A 4-year-old boy, while playing with his 13-year-old cousin, complained of pain in the left elbow. The parents were unable to give a clear explanation of the mechanism of injury, but the child stated that the cousin twisted his arm. He was seen in the office July 28, 1952, the day after the injury. Examination disclosed tenderness over the head of the radius and pain and limitation of supination of the forearm. Extension and flexion of the elbow were normal. An x-ray of the elbow and forearm was normal. A diagnosis of subluxation of the head of the left radius was made. Reduction was carried out by extension of the elbow, followed by supination of the forearm with pressure over the radial head.

CASE 4.—A 2-year-old girl was seen May 27, 1953, because of pain in the left arm and elbow. The mother stated that one week previously, while she was walking downstairs holding the child by the left arm, the child fell, sustaining a pulling injury to the arm. Since the accident the child failed to use the arm normally and complained of soreness about the elbow. Examination revealed supination of the left forearm to be limited, with pain on forcing. Flexion and extension of the elbow were normal. An x-ray of the left upper extremity was made and was normal. A diagnosis of subluxation of the left radial head was made. The forearm was forcibly supinated with the elbow extended, with relief of pain. A posterior plaster splint was applied holding the elbow at 90 degrees flexion and was worn for one week. At the time the splint was removed full supination was present and the child had no pain in the extremity.

CASE 5.—A 2-year-old boy was lifted by his left arm on June 5, 1954. The child immediately began to cry and refused to use the extremity. Examination revealed the child to hold the left forearm in pronation. Attempts to move the wrist or elbow were resisted. X-rays were made of both upper extremities and were normal. Forced supination of the forearm resulted in an audible click, and pain was immediately relieved. A plaster splint was applied to the extremity, holding the elbow at 90 degrees. A week later the cast was removed and the child moved the extremity normally and without pain.

CASE 6.—A 3-year-old girl was seen in the office July 26, 1958. The day previous, while playing with a water hose in the yard, she had fallen and injured the left arm. After the injury she complained of pain about the elbow and refused to use the arm. Examination revealed that the child held the left forearm pronated with the elbow slightly flexed. There was tenderness over the head of the radius, and supination of the forearm was limited, with pain on forcing. The child was sent to the x-ray department for an x-ray of the elbow, and as the forearm was extended during exposure of the films a slight snap occurred in the region of the head of the radius and pain disappeared. The x-rays of the elbow were normal. A diagnosis of reduced subluxation of the left radial head was made.

CASE 7.—A 3-year-old girl was seen Aug. 5, 1958. The mother stated that while playing the child fell, injuring the left arm at the elbow. Examination revealed the left elbow to be held slightly flexed and the forearm pronated. There was no definite tenderness about the elbow, forearm, or wrist. An x-ray was made of the left upper extremity and revealed slight widening of the joint space between the head of the radius and the capitellum of the humerus. A diagnosis of subluxation of the radial head was made. The forearm was extended at the elbow and forcibly supinated, producing a click at the radial head with relief of pain.

Summary

Subluxation of the head of the radius is a traumatic injury occurring in children usually between the ages of 2 and 4 years. The injury is produced by traction on the pronated and extended forearm and causes symptoms of pain in the region of the elbow and limitation of supination of the forearm. X-ray examination may show negative results, but occasionally slight widening of the space between the head of the radius and the capitellum of the humerus is present. Reduction is accomplished by supination of the forearm with the elbow extended, accompanied by slight pressure over the head of the radius and compression of the shaft of the radius against the capitellum of the humerus. A slight click may be palpated as reduction occurs. After reduction the arm should be supported by a sling for several days and traction on the forearm should be avoided for several weeks.

SPONTANEOUS DISAPPEARANCE OF BILATERAL PULMONARY METASTASES

REPORT OF A CASE OF ADENOCARCINOMA OF KIDNEY AFTER NEPHRECTOMY

Leizor Kessel, M.D., Rocky Hill, Conn.

A 65-year-old man, hospitalized because of general weakness and striking weight-loss, was found by roentgenography to have pulmonary lesions suggesting metastases of a tumor. Intravenous pyelography gave evidence of a malignant tumor of the left kidney. A nephrectomy was performed, and the lesion proved to be a clear-cell serous papillary cystic adenocarcinoma. The condition of the patient remained poor for about three months, and the pulmonary lesions increased in size and number. The patient then improved, and at the time of discharge from the hospital the pulmonary lesions were no longer visible. Similar observations have been made in the past. They suggest the hypothesis that these tumors have distinctive properties as to origin and biological activity.

There are only a few cases reported in the literature of spontaneous disappearance of pulmonary metastases of an adenocarcinoma of the kidney. Mann[1] described three cases in which the metastases were present before nephrectomy and disappeared after the primary tumor was removed. One similar case was reported recently by Arcomano and co-workers[2] in which the metastases present before nephrectomy disappeared eight months after operation. There are two more cases, one reported by Bumpus,[3] the other by Beer,[4] in which the metastases appeared after nephrectomy and disappeared spontaneously about five months later.

The number of these cases is rather low if we take into consideration the facts that kidney tumors constitute about 2% of all malignant tumors in adults and that about 80% of all malignant renal tumors are adenocarcinomas.[5] The reason for this may be the prevailing opinion that nephrectomy in the presence of metastases is a questionable procedure[6] and should be done only if the metastatic lesion is isolated and can be removed at the same time as the kidney. Campbell[7] expressed a similar opinion that nephrectomy is the preferred treatment for renal adenocarcinoma (hypernephroma) in the absence of metastases. Referring to the cases of Mann,[1] Bumpus,[3] and Beer[4] he also recommends nephrectomy when only a single metastasis is present, but without removal of the metastasis.

Report of a Case

A 65-year-old man was admitted with the chief complaints of general weakness and loss of 20 lb. (9.1 kg.) of weight in the four weeks before admission. He had been treated in this hospital in 1952 for a left-sided hemiparesis due to cerebral thrombosis, with complete recovery after six months of treatment. He had had no other diseases until the present admission.

Physical findings on admission were essentially unremarkable. The chest x-ray showed several bilateral nodular densities considered to be metastatic lesions. A series of x-ray studies of bone showed no further metastases. Laboratory findings were essentially within normal limits, except for a leukocyte count of 19,920 per cubic millimeter with a normal differential count, and 12 erythrocytes per high-power field in the urine sediment.

In search for a primary tumor intravenous pyelography was performed and the findings showed evidence of a malignant tumor of the left kidney. A nephrectomy was performed and a clear-cell serous papillary cystic tumor (papillary adenocarcinoma) was found. The patient's general condition remained poor for three months postoperatively. A roentgenogram of the chest made two months after surgery showed the metastatic nodules increased in size and number (fig. 1). During the next several weeks the patient started to improve slowly and a chest x-ray made three months after operation showed striking regression of the multiple nodular lesions. The patient continued to improve and gained 20 lb. in weight. A chest x-ray made four months after operation showed complete clearing of both lung fields. The patient was discharged and was followed up on an outpatient basis. The last roentgenogram of the chest, made seven months after operation, showed both lung fields to remain clear (fig. 2).

Comment

Adenocarcinomas of the kidney are classified into three groups[6]: (1) serous papillary cystic tumor (papillary adenocarcinoma) with clear cells or with granular cells, (2) malignant cystadenoma, and (3) alveolar carcinoma. These tumors differ to some extent as to the degree of malignancy. The papillary adenocarcinoma with clear cells, previously called hypernephroma,[7] constitutes the most frequent type of renal tumor.[6] It is interesting that, in all reported cases in which the pulmonary metastasis disappeared after nephrectomy, the kidney tumor was a clear-cell adenocarcinoma. This could lead to the assumption that these tumors may be different in origin and biological activity from other adenocarcinomas of the kidney, as they are less malignant, grow slowly, and often become very large before causing any symptoms.

It is known that metastasis of choriocarcinoma (chorioepithelioma) to the lung may also disappear after removal of the primary tumor.[8] Peterson[8a] first suggested that this may be due to specific antibodies (syncytiolysins), which are produced when chorionic cells reach the maternal blood

---

From the State Veterans Hospital.

stream during pregnancy or labor. Bumpus,[3] referring to Peterson's theory of lysins, suggested that the same theory could also be applied to the cases of hypernephromas in which the pulmonary metastases disappeared spontaneously.

It can be assumed that during operation some microscopic parts of the tumor reach the blood stream and cause the production of antibodies (lysins). Some of the particles may develop into metastases before the titer of the antibodies has reached a level sufficient to dissolve them; they are, however, dissolved later, when the titer has increased to a high enough level. This would explain the cases reported by Bumpus[3] and Beer[4] in which the metastases appeared after nephrectomy and disappeared about five months later.

Sometimes the metastases do not appear at all after operation in spite of extension of tumor tissue into the renal veins (eight cases mentioned by Bumpus[3]). In these cases the titer of the antibodies probably increased so fast that the small particles which reached the blood stream during surgery were dissolved before they could grow. It is even more probable that small amounts of antibodies were present in blood before operation, as small tumor particles may break into the blood stream under normal conditions. The titer of these antibodies would be low before nephrectomy because of reaction to the primary tumor; but after nephrectomy, the titer would be high enough to dissolve the particles reaching the blood stream during operation and thus prevent metastases.

It was also observed that the general condition of almost all patients in the described cases was poor for several months after nephrectomy. This could be due to increased amounts of toxic products from the destroyed tumor cells. The morbidity of the patients before nephrectomy could also be due to these toxic products rather than to toxins produced by the tumor cells as is generally supposed.

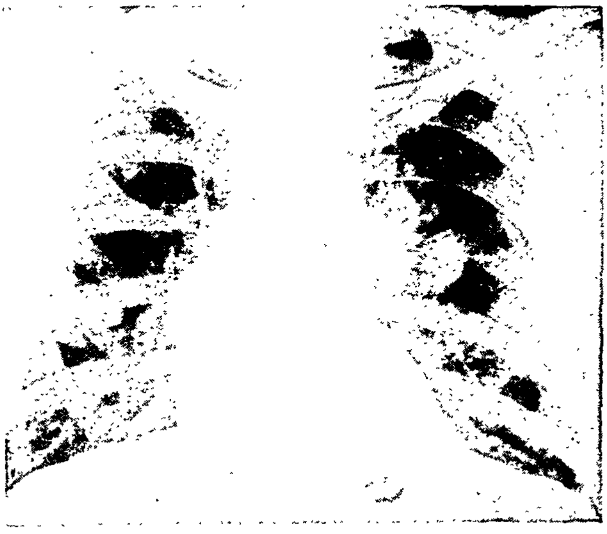

Fig. 1.—Roentgenogram of the chest made two months postoperatively, showing enlarged metastatic nodules.

The case presented by Arcomano and co-workers[2] is interesting because the patient developed a metastasis to the brain one year after the disappearance of the pulmonary metastases. This single metastasis was removed and the patient remained asymptomatic for 17 months after surgery. If we accept the hypothesis that antibodies are responsible for the disappearance of the pulmonary metastases, then the development of a metastasis to the brain would suggest that the antibodies either cannot pass the blood-brain barrier or are present there in much smaller concentrations than in the blood and, therefore, cannot prevent the growth of the metastatic cells.

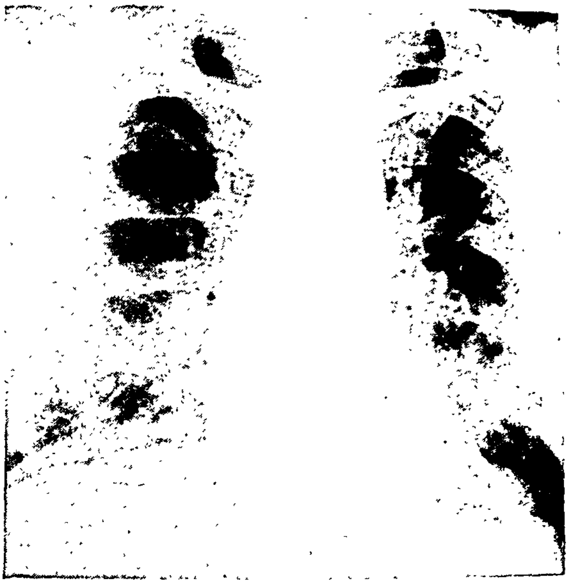

Fig. 2.—Roentgenogram of the chest made seven months postoperatively, showing clear lung fields.

The antibody theory of Peterson[8a] and Bumpus[3] could also explain why in some cases the metastases appear only after many years. An antibody titer which is not high enough to dissolve metastatic cells would still prevent their growth for many years rather than destroy them completely. If for some reason the antibodies disappear from the blood, then these cells are able to develop again and produce metastases.

All these considerations are of hypothetical nature, as in the last 30 years only these few cases have been described in the literature, and further investigations are needed to explain these interesting findings.

State Veterans Hospital, West Street.

Dr. Miriam Liberson, Chief of the Radiology Department, interpreted the roentgenograms.

Dr. Charles E. Jacobson Jr. performed the nephrectomy.

DOUBLE-BLIND EVALUATION OF METHYLPHENIDATE (RITALIN) HYDROCHLORIDE

ITS USE IN THE MANAGEMENT OF INSTITUTIONALIZED GERIATRIC PATIENTS

Fred T. Darvill Jr., M.D., Sedro Woolley, Wash.

The effects of methylphenidate were compared with those of a placebo in 70 senile patients committed to a state institution because of mental disturbances. Neither the patients nor those who rated their behavior (orientation, appetite, continence, cooperativeness, activity, rationality, personal care, and irritability) knew whether a given patient was receiving the drug or the placebo. Among those who received the drug, two dosage schedules were used, the doses being increased weekly until some patients were receiving 60 mg. daily during the sixth week of the study. No significant differences were found between the test and contratest groups as regarded weight, pulse rate, or behavior ratings. A statistically significant lowering of the blood pressure was found among the subjects who received a maximum daily dose of 30 mg. of methylphenidate but was not found among those who received the maximum daily dose of 60 mg. No undesired side-effects were observed in this study, but the drug in the dosages used did not have any convincing effect on the physical or mental status of the patients.

Methylphenidate (Ritalin) hydrochloride, a psychotropic amine, has been evaluated as to its effect in a variety of psychiatric conditions, including depressions of the aged,[1] severe regression,[2] and schizophrenia.[3] Control groups were used in these studies. Benefit was reported in the first two of the above groups as a result of administration of this drug.

Dube and co-workers[4] evaluated 20 senile patients utilizing a double-blind technique and reported that methylphenidate in a dosage of 10 mg. given four times a day definitely improved behavior when compared to reserpine (1 mg. daily) or to placebos. Patients so studied served as their own controls. However, the number of patients studied is too few to permit drawing other than tentative conclusions.

Ferguson and Funderburk[5] have reported methylphenidate to be of value in the management of primarily retarded committed geriatric patients. Davidoff and associates[6] gave the drug to 10 geriatric patients and reported good results in 6. Side-effects (tension and insomnia) were seen in six patients and were especially evident in those who did not show improvement while receiving the drug.

The latter two studies did not use control groups. The rating of subjective phenomena depending primarily on the judgment of the investigators is known to be unreliable and the results subject to question unless the study is carried out with the double-blind technique.[7] This is particularly true in investigating senile behavior, where any degree of attention or interest will frequently result in an improvement in the parameters being evaluated.[8] To date, no serious effect in any organ or system or in blood pressure or pulse rate has been noted with the use of this drug.[9]

From the Northern State Hospital, Sedro Woolley, Wash., and the Department of Medicine, University of Washington School of Medicine, Seattle.

After reviewing the above papers it was felt worthwhile to evaluate the effect of this drug on senile behavior in a controlled fashion, with use of a sufficient number of patients to allow accurate statistical evaluation. Accordingly, a double-blind evaluation of methylphenidate in the management of institutionalized geriatric patients was undertaken.

Method of Study

All patients studied in this series were committed to Northern State Hospital, Sedro Woolley, Wash., by the superior courts of the state of Washington. Sixty of the subjects who completed the course of study were selected from newly admitted patients, 60 years of age and older, sent directly to the medical geriatric admission ward.[10] All newly admitted patients had a complete history and physical examination and a mental status examination; laboratory studies included a white blood cell count, hematocrit value determination, urinalysis, blood urea nitrogen level determination, serologic tests for syphilis, chest x-ray, and electrocardiogram. After the above evaluation was completed, all patients who were diagnosed as having chronic brain syndrome due to cerebral arteriosclerosis or to senility were considered for the study. A study of higher priority was being conducted simultaneously which required the rejection of patients found to have the following physical conditions: angina, past or present; previous myocardial infarction; congestive heart failure, past or present; diabetes mellitus requiring insulin or tolbutamide therapy; chronic renal disease manifested by a blood urea nitrogen level of over 40 mg. %; diastolic hypertension manifested by a sustained diastolic pressure of over 110 mm. Hg; adrenal cortical hypofunction (Addison's disease); and peripheral vascular insufficiency of severe nature. The 60 newly admitted patients finally selected for this study all had one or more of the above physical disabilities; it can be seen, then, that these patients included in this study had poorer physical health than the average geriatric patient admitted to this hospital. Further indication of this selection was the fact that the average age of the patients in this group was 78 years, whereas the over-all average age of the geriatric patients was 74 years on admission.

Ten of the patients who completed the course of study were long-term occupants of geriatric wards. These patients were not screened on the basis of physical disease or laboratory findings and therefore represented the average geriatric patient as far as physical health and metabolic status was concerned. Five additional patients were started on this study but did not complete the eight-week course for reasons to be detailed later.

After a minimum of 10 days of hospitalization, the weight, pulse rate, and blood pressure were determined and the following eight parameters evaluated: orientation, appetite, continence, cooperativeness, activity, rationality, personal care, and irritability. A word description of the baseline state was then entered on the patient's rating sheet. These ratings were made in conference with the ward nurse, the ward physician, the attending staff, and the investigating physician. With the case number used as the sole criterion, these patients were then assigned alternately to either drug A or drug B, one of which was of methylphenidate, 10 mg., and one of which was a physically indistinguishable placebo. No one in the institution was aware of which drug was the active one and which was the placebo. No effort was made to assign patients to the study because of the degree of mental defect present, the degree of activity or retardation, or the findings in any of the evaluated parameters.

In 30 patients (group 1), 24 men and 6 women aged 65 to 91 years, the dosage was as follows: first week, one tablet daily; second week, one tablet twice a day; third to sixth weeks, one tablet three times a day; and, seventh to eighth weeks, no medication. For those patients who received the active drug, the dosage was 10 mg. daily the first week; 20 mg. daily the second week; and 30 mg. daily for the third to sixth weeks.

In 40 patients (group 2), 22 men and 18 women aged 65 to 98 years, the dosage was as follows: first week, one tablet daily; second week, one tablet twice a day; third week, one tablet three times a day; fourth week, one tablet four times a day; fifth week, one tablet five times a day; sixth week, two tablets three times a day; and, seventh to eighth weeks, no medicaments. For those who received the active drug, the dosage was 10 mg. daily the first week and weekly increments of 10 mg. daily were given for the next five weeks, so that the dose on the sixth week of the study was 60 mg. daily.

Toward the end of each of the eight weeks the blood pressure, pulse rate, and weight were again determined and the eight behavior parameters were reevaluated by the same rating team and compared to the base line on the following scale: much improved, some improved, no change, worse, and much worse. At the conclusion of the eight-week period an over-all evaluation of the response to therapy was made, both in words and with the rating scale. Any medical diseases or additional behavioral manifestations occurring during the study were noted.

Results

Of the 75 patients at the start of this study, 70 completed the eight-week course of medication and observation. Two patients, one receiving methylphenidate and one receiving the placebo, died suddenly during the study. Clinically, these deaths were presumed to be due to coronary artery disease. One patient receiving methylphenidate had a cerebral vascular accident which necessitated cessation of oral drug therapy. One patient receiving the placebo became so agitated that emergency electroshock therapy was imperative. One patient was dropped from the study for treatment of hypothyroidism bordering on myxedema which was suspected clinically but not confirmed before the study was instituted.

In the 30 patients completing the study in group 1, there were no significant medical illnesses occurring in those patients who received methylphenidate. Among those given the placebo, a carbuncle, one case of pneumonia, and one case of paroxysmal supraventricular tachycardia appeared. Of the 40 patients in group 2, one case of bronchitis, one case of lethargy, and one grand mal epileptic seizure were noted in the patients treated with methylphenidate. Two cases of pneumonia and one case of congestive heart failure were noted in the placebo group.

Over-all Response to Methylphenidate and Placebo Therapy in Geriatric Patients

	Much Improved, No.	Some Improved, No.	No Change, No.	Some Worse, No.	Much Worse, No.
Group 1					
Placebo	2	5	7	1	0
Methylphenidate	2	3	8	2	0
Group 2					
Placebo	1	6	10	3	0
Methylphenidate	2	4	12	1	1

No significant changes occurred in weight or pulse rate in either the experimental or control group. In group 1 (but not group 2) a significant ($p=0.01$) reduction in blood pressure occurred in the group treated with methylphenidate, as compared to the group treated with the placebo.

No statistically significant differences in any of the evaluated parameters could be demonstrated between the experimental and control groups in either dosage range. No statistically significant difference could be detected in the over-all response between the experimental and control groups in either dosage range. The table details the over-all response in both groups.

Comment

It is apparent that, in this group of elderly, senile, institutionalized patients, methylphenidate in adequate doses was of no value in improving the senile state. The improvement noted on previous studies and in this study was most likely due to the increased attention and interest which the patients received when selected for study. The need to carefully control studies in evaluating drugs of all kinds, and particularly drugs which may improve or influence the senile state, is again demonstrated.

The blood pressure change noted in group 1 is interesting, and it is suggestive that this drug may conceivably act as an antihypertensive agent. However, no blood pressure change of significance was noted in group 2. Although the blood pressure changes noted were statistically significant, it seems probable that these changes were coincidental. Further study is needed in this regard.

Summary

Seventy senile, institutionalized patients were studied with use of the double-blind technique during treatment with methylphenidate (Ritalin) hydrochloride and an identical placebo. No significant toxicity was noted in two groups receiving different dosages. No statistically significant improvement in the senile state could be demonstrated as a result of such treatment with methylphenidate.

MEPHENTERMINE SULFATE FOR TREATMENT OF ARTERIAL HYPOTENSION

Travis Winsor, M.D., Los Angeles

The possibility of using mephentermine sulfate to treat various types of hypotension was studied in three groups of patients. Group 1 consisted of 10 patients who had hypotensive episodes during a rigorous course of treatment for essential hypertension or hypertensive renal disease. Group 2 consisted of 10 patients who had hypotensive episodes related either to diabetes or to cerebral arteriosclerosis. Group 3 consisted of 10 patients with a variety of nonspecific hypotensive syndromes. Measurements of blood pressure, of maximum ventricular excursion by roentgenkymography, of the I-J wave in ballistocardiograms, of blood flow in the finger, and of peripheral vascular resistance showed that mephentermine in the dosages used corrected the hypotension by both central and peripheral action. It was active when given orally, intramuscularly, or intravenously. For the type of hypotension seen in group 2, a daily oral dose of 12.5 mg. after the morning or noonday meal usually sufficed.

Hypotension may be caused by or associated with diabetes, cerebrovascular insufficiency, and a miscellaneous group of other diseases commonly characterized by a tendency to lethargy, fatigability, daytime drowsiness, and postural dizziness. The same symptoms also are produced in a certain percentage of patients by the ganglion-blocking agents, although considerable research has been directed toward reducing the severity of this complication to antihypertensive treatment. Trimethidinium methosulfate, for example, one of the newer asymmetric bisquaternary compounds (fig. 1), which exerts a potent ganglioplegic activity, induces postural hypotensive symptoms in about the same incidence as do other ganglion blockers. Its formula is d-[N-methyl-N-(γ-trimethylammoniumpropyl)] 1-methyl-8,8-dimethyl-3-azobicyclo [3.2.1] octane dimethosulfate. Parenteral or oral dosage, in the usually recommended range, exerts ganglioplegic activity for approximately 12 hours.

Mephentermine sulfate (N,α,α,trimethylphenethylamine sulfate) is a sympathomimetic pressor amine. This compound produces an antiarrhythmic [1] and positive inotropic action and also vasoconstriction.[2] In dogs, coronary flow has been increased under constant coronary perfusion pressures.[3] Mephentermine may be administered orally or parenterally and has been used clinically for prevention or treatment of hypotension associated with spinal anesthesia [4] and for correction of depressed blood pressure associated with shock in myocardial infarction [5] and obstetric delivery.[6]

The present study was designed to determine the effectiveness of mephentermine in controlling an excessive hypotensive response to the ganglionic blocking agent, trimethidinium methosulfate, and management of hypotension in a variety of other conditions.

Methods and Materials

The series consisted of 45 outpatients 23 to 72 years old, with an average of 49 years. Eighty per cent were men.

Group 1 (table 1) comprised 10 patients (7 men and 3 women), with an average age of 48 years, who had essential hypertension or whose elevated blood pressure was caused by polycystic kidney disease, glomerulonephritis, or obstruction of the renal artery (Goldblatt's hypertension). Retinopathy of grade 2 or 3 severity, according to the Keith-Wagener criteria, was present in every case. All had been maintained on a low-sodium diet and had been receiving diuretics and Rauwolfia serpentina. Trimethidinium methosulfate also had been administered orally, on a fasting stomach, at intervals of 12 hours, for one to five months. Total daily dosages ranged from 40 to 120 mg., with an average of 60 mg. Under this regimen most of the patients obtained reduction in blood pressure but occasionally experienced postural hypotension three to four hours after the morning medication. When hypotensive symptoms occurred during the course of trimethidinium therapy, 30 mg. of mephentermine was administered intramuscularly; later a dose of 25 mg. was administered orally for each hypotensive episode. The blood pressure was then read at intervals for two hours.

Group 2 (table 2) consisted of 10 patients, 4 with diabetes and 6 with cerebrovascular insufficiency caused by arteriosclerosis. In these patients orthostatic hypotension was particularly troublesome during hot weather, during convalescence from infection or operation, and in the presence of fatigue. During hypotensive periods 25 mg. mephentermine was administered orally after breakfast each morning.

Of the 10 patients in group 3 who had nonspecific hypotensive syndromes, 4 had neurasthenia, 3 were suffering from malignant processes, 2 had chronic infections, and 1 was convalescing after operation.

From the Department of Medicine, University of Southern California School of Medicine, and the Heart Research Foundation.

Orthostatic hypotension, with postural dizziness, depression, and lethargy, was episodic and aggravated by heat and fatigue. The control blood pressure with the patients standing averaged 92 mm. Hg systolic (range, 88 to 100) and 55 mm. Hg diastolic (range, 42 to 62). Mephentermine was administered orally, in a dose of 25 mg., after breakfast.

Determinations of Blood Pressure, Cardiac Output, and Pulse Volume.—Segmental and digital plethysmograms were taken with equipment previously described.[7] Roentgenkymograms were recorded with the Liebel-Flarsheim kymograph. Ballistocardiograms were taken with the Nickerson low-frequency standardized table. Blood pressure was determined with a mercury manometer or with the Colson automatic blood pressure recorder.

Orthostatic hypotension was arbitrarily defined as blood pressure, with the patient in the standing position, of 100 mm. Hg systolic or less and 60 mm. Hg diastolic or less.

Results

Group 1 (table 1).—After administration of mephentermine, a rise in blood pressure occurred for all patients in group 1, in both standing and supine positions. The highest pressure with the patient standing is listed for each in table 1. Most patients were symptomatically improved; weakness and dizziness were eliminated or diminished.

Table 1.—*Effect of Mephentermine on Orthostatic Hypotension Produced by Trimethidinium*

				Blood Pressure, Mm. Hg

Minimum				120	85	90	60	130	90	120	82
Maximum				185	102	102	72	185	115	148	99

The blood pressure response of the patient in case 6 is shown in figure 2. The hypotension was demonstrated by segmental plethysmographic record taken from the arm (fig. 3). With the patient in the supine position, the arm cuff was inflated to 100 mm. Hg (pressure at which the maximum pulsation was obtained). The blood pressure was 160/100 mm. Hg; the amplitude of the pulse curve was 0.6 cc. per pulse. As soon as the patient assumed the standing position, with the same pressure in the cuff, the amplitude was 0.1 cc. per pulse. On prolonged standing the amplitude of pulsation was reduced. One hour after intramuscular administration of 30 mg. of mephentermine the cuff was inflated to 115 mm. Hg (pressure at which the maximum pulsation was obtained). With the patient supine, the blood pressure was 185/115 mm. Hg and the pulse volume 0.93 cc. per pulse. As soon as the patient stood, the pulsation was reduced to 0.5 cc. per pulse and the blood pressure to 120/80 mm. Hg.

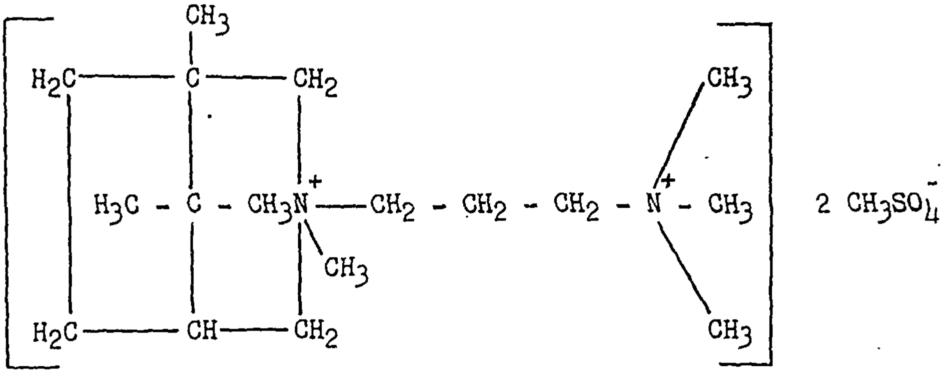

Fig. 1.—Trimethidinium methosulfate.

Group 2 (table 2).—A definite increase occurred in systolic and diastolic blood pressure with the patients standing as well as in the supine position. Three patients reported that they experienced less dizziness on standing, two were less fatigued during the day, three had less daytime drowsiness, and two reported subsidence of depression. On the 25-mg. dose, two patients reported nervousness and two insomnia and one each experienced quivering, vertigo, and nausea. For these the dose was reduced to 12.5 mg., after which there were no side-effects. Five of the group continued taking mephentermine in daily doses of 12.5 mg. for four months. A satisfactory antihypotensive action was maintained throughout this period; no tachyphylaxis occurred.

Figure 4 shows the effect of mephentermine on the blood pressure of the patient in case 17 (table 2) after an oral dose of 12.5 mg. taken in the fasting state. The blood pressure rose from 110/68 to 118/73 mm. Hg. Similar results were obtained in five patients (table 1) whose blood pressure was determined with the Colson recorder.

Maximum	70			119	82	100	79	134	88	120	82

Group 3.—One hour after the oral dose of mephentermine the systolic blood pressure averaged 107 mm. Hg (range, 98 to 118) and the diastolic 64 mm. Hg (range, 52 to 78). For three patients the dose of mephentermine was reduced to 12.5 mg., since the 25-mg. dose seemed excessive and had induced some nausea or nervousness.

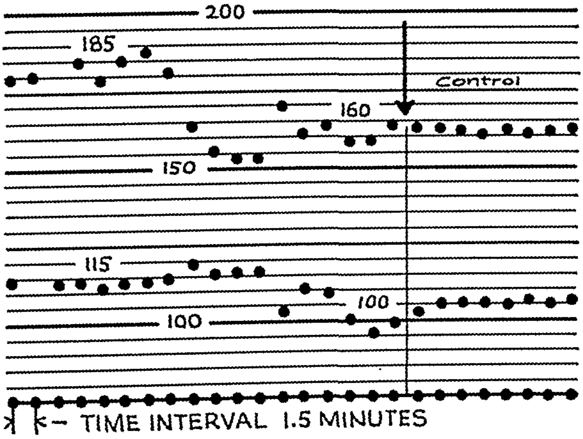

Fig. 2 (case 6).—Blood pressure of patients with severe essential hypertension. Postural hypotension occurred after administration of trimethidinium methosulfate and patient was dizzy on standing; hypotensive symptoms were controlled by intramuscular injection of 30 mg. of mephentermine. Arrow indicates time of injection. Read record from right to left.

Mechanism of Action.—The mechanism of action was studied by observing the effects of mephentermine on the heart, as recorded on the roentgenkymogram and the ballistocardiogram, and on the peripheral circulation by determination of the finger blood flow and local peripheral resistance.

A roentgenkymogram was taken for five patients. The maximum amplitude of pulsation of the left ventricular border was recorded before administration of mephentermine and one hour after intramuscular injection of 25 mg. (table 3). The studies made before antihypotensive medication were done during episodes of orthostatic hypotension. The roentgenograms were taken with the patient in the standing position. A definite increase occurred in the amplitude of pulsation one hour after administration of the dose.

Ballistocardiograms were taken for five patients, three with diabetes and two with cerebrovascular insufficiency (table 4). All had a tendency toward hypotension in the supine position. The height of the I-J wave was measured in millimeters before administration of mephentermine and one hour after intramuscular injection of 25 mg. In all cases the amplitude of the I-J wave increased after the injection.

TABLE 3.—*Mechanism of Action of Mephentermine for Correction of Hypotension: Results of Roentgenkymography of Chest*

		Maximum Excursion Left Ventricle (Mm.)

21	Diabetes	3.0	4.0
22	Diabetes	2.5	3.5
23	Diabetes	2.5	3.5
24	Cerebrovascular insufficiency	3.0	4.5
25	Cerebrovascular insufficiency	2.5	3.5
Mean		2.7	3.8
Minimum		2.5	3.5
Maximum		3.0	4.5

Finger flow and peripheral resistance were measured in five patients, three of whom had Raynaud's disease, for which sympathectomy affecting the upper extremities had been done. Two had thromboangiitis obliterans. The blood pressure was recorded by the auscultatory method, with use of a mercury manometer at the elbow. Finger flow was determined with a vein-occluding digital cuff. Peripheral resistance was calculated by taking the sum of the systolic blood pressure and twice the diastolic pressure, dividing by 3 to obtain the mean arterial pressure, and inserting this figure into the formula, as follows: Mean pressure in millimeters of mercury÷blood flow in cubic millimeters per 4 cc. of digit per second=the peripheral resistance units (PRU).

Comment

The positive inotropic action of mephentermine has been demonstrated by Freiheit[8] and others.[9] Oppenheimer[10] has shown that this compound decreases the refractory period and increases the conduction velocity in the cardiac muscle. A peripheral effect of mephentermine is suggested by the beneficial action of the compound when it is used in conjunction with spinal anesthesia.[4]

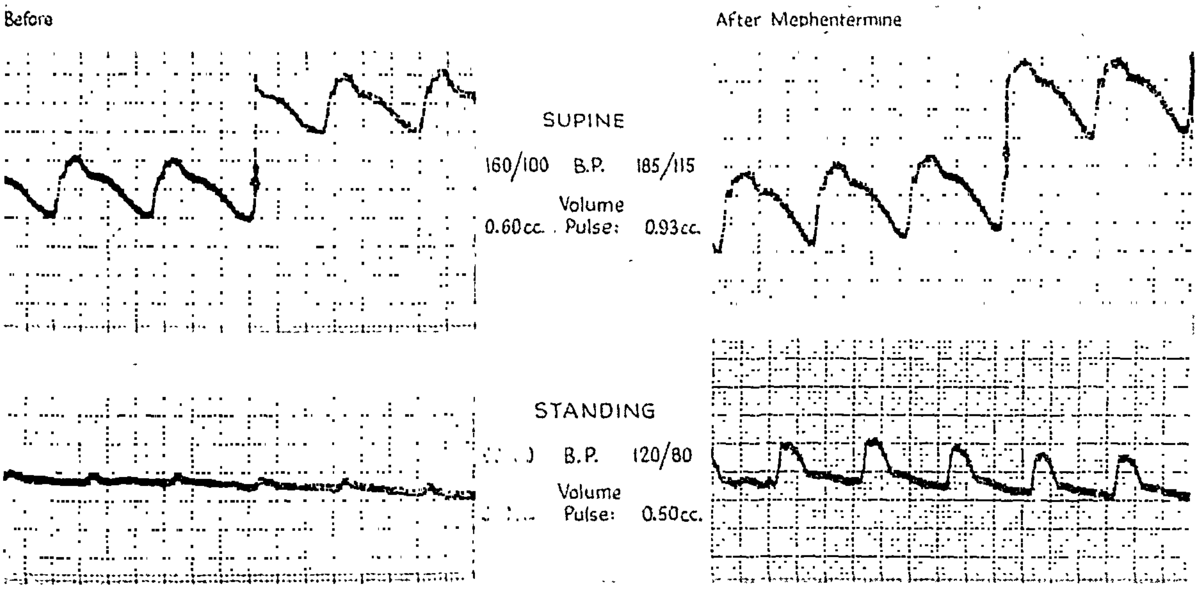

Fig. 3 (case 6).—Pulse volume in arm before and after administration of mephentermine. Standardization represents volume change of 1 cc.

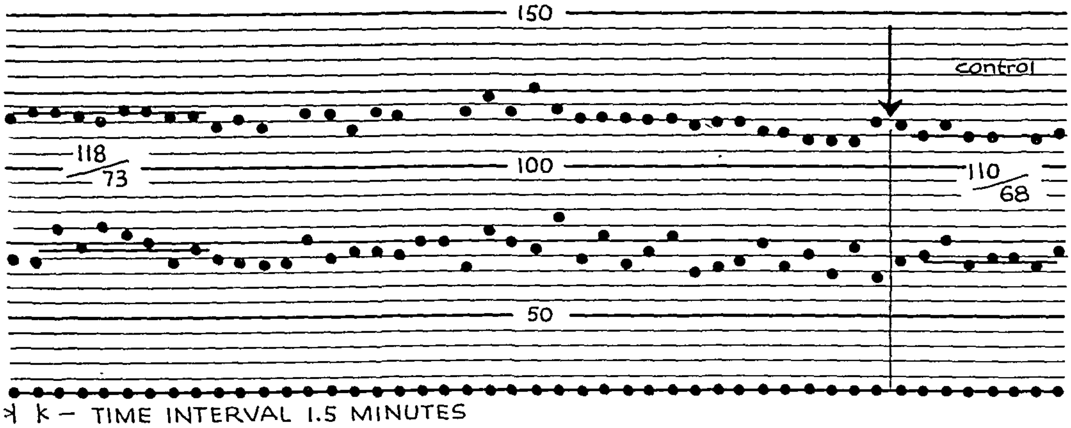

Fig. 4 (case 17, table 2).—Effect on blood pressure of oral dose of 12.5 mg. of mephentermine administered on fasting stomach (read from right to left).

Measurements made before administration of mephentermine and one hour after intramuscular injection of 25 mg. showed decrease in blood flow with increase in peripheral resistance (table 5).

As a result of the antihypotensive medication, there was a definite decrease in the amplitude of pulsation in the digit from an average of 2.0 to 0.5 cu. mm. per pulse. A typical record is that of the patient in case 32 (table 5), which is shown in figure 5.

The findings in this study indicate that mephentermine is useful for correction of hypotension from various causes and that the mechanism of action is both central and peripheral. The excursion of the left ventricular pulse and the force of the cardiac contraction were increased, and there was a mild increase in the local peripheral resistance and decrease in the amplitude of the pulsation at the fingertip. A positive inotropic and a peripheral action were induced by intramuscular injection of

25 mg. of the compound. This dose is small in comparison with that used for reversal of acute shock in myocardial infarction. In such cases an initial intramuscular or intravenous injection of 50 mg. is often required to return the blood pressure to normotensive levels.

The usefulness of mephentermine has been demonstrated for treatment of hypotensive episodes during medication with ganglionic blocking agents.

TABLE 4.—*Data from Ballistocardiogram Taken Before and After Intramuscular Injection of Mephentermine*

		Height of I-J Wave (Mm.)	
Case No.	Diagnosis	Before	After 25 Mg. IM
26	Diabetes	3.0	5.0
27	Diabetes	4.5	7.5
28	Diabetes	5.0	6.5
29	Cerebrovascular insufficiency	4.5	7.0
30	Cerebrovascular insufficiency	6.0	9.0
	Mean	4.6	7.0
	Minimum	3.0	5.0
	Maximum	6.0	9.0

When symptoms of postural hypotension are severe the compound should be administered intramuscularly or intravenously. For mild symptoms the oral form is adequate.

Hypotension associated with diabetes or cerebrovascular insufficiency often can be treated adequately with a daily oral dose of 12.5 mg. of mephentermine, administered after breakfast. This dose is well tolerated, appears not to produce tachyphylaxis, and is usually sufficient to support the blood pressure of patients who exhibit a nonspecific hypotensive syndrome.

Since mephentermine exerts a prolonged activity (e. g., in this series a dose of 12.5 to 25 mg. sufficed for 12 to 24 hours), the compound should not be taken later than 4 p. m. because of the possibility of insomnia. The larger the dose, the longer is the action and the greater the tendency toward sleeplessness. In properly adjusted dosage, mephentermine medication may be continued indefinitely.

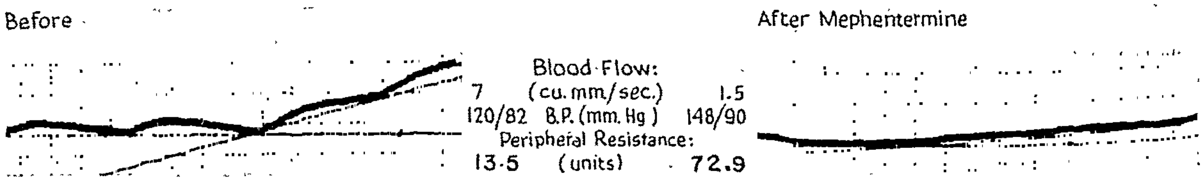

Fig. 5 (case 32, table 5).—Effect of mephentermine on finger blood flow and peripheral resistance.

Summary

Hypotension may be caused by or associated with a variety of diseases in which abnormality of the cardiovascular system is involved and may attend use of the ganglionic blocking agents. Mephentermine sulfate was given intramuscularly to 45 adult patients to correct an excessive response to use of trimethidinium methosulfate and orally, after a meal, to control hypotension associated with diabetes, arteriosclerotic cerebrovascular insufficiency, and a variety of nonspecific hypotensive syndromes.

The cardiac output, pulse volume, and peripheral resistance were measured by segmental and digital plethysmograms, roentgenkymograms, and ballistocardiograms; the blood pressure was recorded with a mercury manometer or the Colson automatic recorder. Orthostatic hypotension was defined as systolic pressure of 100 mm. Hg or less and diastolic pressure of 60 mm. Hg or less with the patient in the standing position.

TABLE 5.—*Finger Blood Flow and Peripheral Resistance Before and After Intramuscular Injection of Twenty-five Milligrams of Mephentermine*

		Brachial Blood Pressure, Mm. Hg		Finger Flow, Cu. Mm./4 Cc./Second		PRU*	
Case No.	Diagnosis	Before	After	Before	After	Before	After
31	Raynaud's disease	130/70	150/85	14	2.0	6.4	53.3
32	Raynaud's disease	120/82	148/90	7	1.5	13.5	72.9
33	Raynaud's disease	128/82	158/98	12	1.0	8.1	118.0
34	Thromboangiitis obliterans	110/68	150/92	19	4.0	4.3	27.8
35	Thromboangiitis obliterans	118/78	160/102	24	6.0	3.8	20.3
	Mean	121/76	153/93	15.2	2.9	7.2	58.5
	Minimum	110/70	148/85	7	1.0	3.8	20.3
	Maximum	130/82	160/102	24	6.0	13.5	118.0

* PRU = Peripheral resistance unit.

Intramuscular injection of 25 to 30 mg. of mephentermine sufficed to counteract the excessive response to a ganglionic blocker. For mild symptoms the orally given form was adequate. For hypotension associated with diabetes, cerebrovascular insufficiency, or other conditions, a daily oral dose of 12.5 mg. after a meal was sufficient; for severe symptoms 25 mg. might be required. In properly adjusted dosage, mephentermine medication may be continued indefinitely.

The mechanism of action of mephentermine is both central and peripheral. Intramuscular injection of the compound produces a positive inotropic action and induces a mild increase in local peripheral resistance with decrease in the amplitude of the pulsation at the finger tip. The pressor activity is prolonged; hence, the dose should not be administered after 4 p. m. because of the possibility of insomnia.

3875 Wilshire Blvd. (5).

The mephentermine sulfate used in this study was supplied by Wyeth Laboratories, Los Angeles.

This study was supported, in part, by a grant from the Ventura County (Calif.) Heart Association.

Sally Cody supplied technical assistance in this study.

CLINICAL NOTES

SWEAT BAND DERMATITIS—REPORT OF THREE CASES

George E. Morris, M.D., Boston

Sweat band dermatitis has not recently been described in the medical literature of the United States, and one of the underlying reasons for its low incidence is the fact that chrome-tanning compounds are not used in the preparation of sweat bands. Therefore, the leather of sweat bands contains, if any, only a limited amount of chromium. The vegetable tannins which are used are not potent sensitizers.

The use of chrome-tanned leather in sweat bands obtained under its procurement program has been specifically prohibited by the United States government in the two pertinent specifications which are now in force. "Military Specification MIL-B-3577A (S&A), Jan. 19, 1954, Band, Sweat, Cap (Leather)," which covers the requirements for sweat bands used in caps worn by military personnel, states that "chrome-tanned leather will not be permitted." "Interim Federal Specification GG-H-00166a (GSA-FSS), April 18, 1956, Headbands, Mirror," which covers mirror headbands for use by practitioners and specialists, states that "the leather shall be well tanned with vegetable tanning materials."

These governmental restrictions, as well as the self-imposed restrictions of the larger manufacturers of sweat bands in the United States, against the use of chrome-tanned leather now appear to have been in the best interests of the public. For it has now been established [1] that the lactic acid and lactate portions of human perspiration can leach chrome salts from chrome-tanned leather and deposit them onto the skin and that sensitization dermatitis can result from the basic chromic sulfate—$[Cr(H_2O)_5OH]\ SO_4$—thus deposited on the skin. Considering the uniquely close contact of the sweat band with the forehead, it would have been inevitable, had these restrictions not been in effect, that some persons would have developed dermatoses from this trivalent chromium sensitizer. This basic chromic sulfate is not related to either chromates or dichromates, as is evident from figure 1. The soluble chromates and dichromates form yellow and orange solutions for the most part, whereas the basic chromic sulfate salt found in chrome-tanned leather forms a green solution.

This basic chromic sulfate compound is now available for patch-testing purposes and has caused positive patch-test reactions in a 0.2% solution.[1] It is the chemical that should be used if one suspects

---

Member, Committee on Occupational Dermatoses, Council on Industrial Health, the American Medical Association.

that the chromium of the leather is the cause of a person's dermatitis. There is neither chromate nor dichromate in shoe leather. The leaching of basic chromic sulfate by the lactic acid and lactate portions of the perspiration has caused dermatoses of the hands and feet from the wearing of chrome-tanned leather gloves and shoes in sensitized persons.[2]

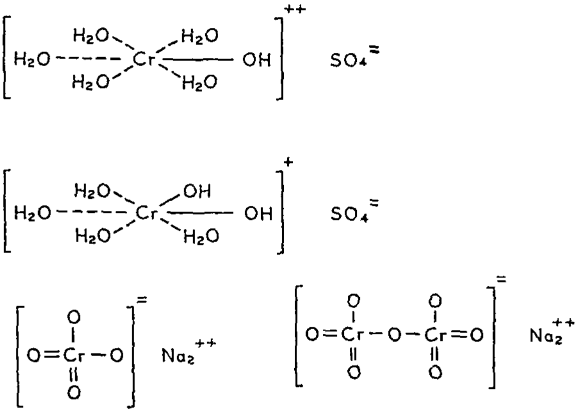

Fig. 1.—Formulas of complex coordination compounds found in a chrome-tanned leather: (*top*) one-third basic; (*center*) two-thirds basic; (*bottom left*) chromate ion; and (*bottom right*) dichromate ion.

Chemical analysis of a nurse's stockings (whose white shoes had shown green chrome-discoloration) has shown that they contained a considerable quantity of trivalent chromium salts. This is the first report of the finding of trivalent chromium salts in stockings. The sample was extracted in a Soxhlet extractor with water and the extract concentrated. A qualitative test for hexavalent chrome was run with use of diphenylcarbazide as a reagent. This test gave negative results. A portion of the extract was then dried down and oxidized to the hexavalent form and the diphenylcarbazide test repeated. In this case there was a very strong positive reaction for hexavalent chrome. This means that in the stocking there was practically a complete absence of hexavalent chrome but a considerable quantity of trivalent chrome.

Chromium salts, however, are rarely used in the tanning of sweat bands in the United States, and the only recent cases of sweat band dermatitis that have been reported (both were in the foreign literature) have been described as being due to Thioprene latex used as a sizing agent in paper or cloth sweat bands[3] or as being due to a laurel oil with which some hats are treated.[4]

This report deals with three cases of typical sweat band dermatitis seen in my practice, one from paper and the other two from rubbing substances onto the sweat band by the hands.

Report of Cases

Case 1.—A worker in a cordage plant developed a generalized dermatitis (extending from his neck to his feet) from the oiled fibers of the rope. He was kept out of work, given treatment, and completely cleared of his eruption. He was told to destroy all his old clothing, and new protective clothing was supplied. He returned to work and was seen one week later with a dermatitis of the sweat band area. The only article of clothing he had not discarded was an old hat that he was accustomed to wear at work. He volunteered the information that over a period of months he was in the habit of wiping the accumulated sweat off the sweat band with his oily hands, and it was evident that the band had thus become saturated with oil. When he wore the hat subsequently, the oil caused an eruption on his forehead, although it had not done so at the time of his previous eruption. Oil was extracted from the sweat band with ether; the ether was then evaporated; and the patient had a positive reaction to the residual oil thus extracted from the sweat band.

Case 2.—This patient was employed as a painter and wore the typical painter's hat. The sweat band was a piece of paper impregnated with a sizing material, the nature of which could not be determined. After he had worn the hat some months, a typical crusted sweat band dermatitis ensued. There was a sharp outline of erythema, with scaling and hemorrhagic crusting encircling the head where the sweat band contacted the skin. A patch test to the paper gave positive results after 24 hours. The man was given treatment.

Case 3.—A worker in a tannery had suffered from a dermatitis from a tanning solution over a period of 10 years. During the last eight months it had been spreading. On examination, he showed a papular eruption of the arms, forearms, and hands, parts of his body in immediate contact with the solution, and similar dermatitis in areas about the knees where splashes of the chemical came in contact with his clothing above the high boots that he wore. He had a rash of the sweat band area, where he said he had been wiping the perspiration off of the sweat band.

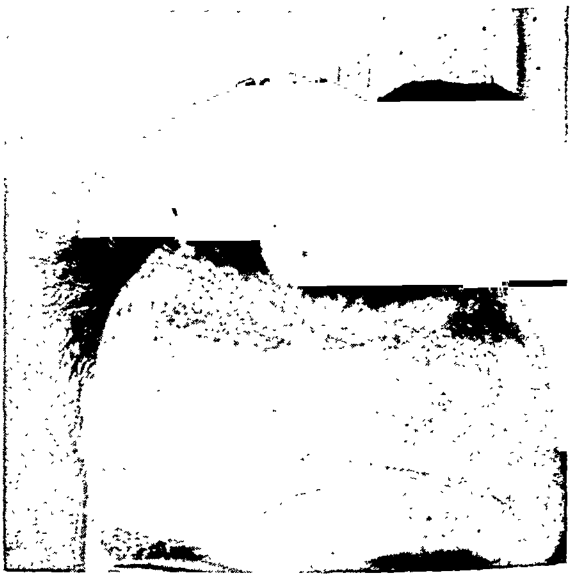

Fig. 2 (case 2).—Typical case of sweat band dermatitis.

Summary and Conclusions

Chrome-tanned leathers are not used in sweat bands. This is the first report that trivalent chromium salts have been found in stockings. Basic chromic sulfate is a cause of dermatitis among sensitized persons. Sweat band dermatitis is not common. However, the diagnosis is simple, and the cause may be the finishing material of synthetic fibers or of paper dissolved onto the skin by perspiration or it may be due to substances rubbed onto the sweat band by the hands.

SHOCK AFTER ADMINISTRATION OF PROCHLORPERAZINE IN PATIENT WITH PHEOCHROMOCYTOMA

REPORT OF A CASE WITH SPONTANEOUS TUMOR DESTRUCTION

Irwin A. Brody, M.D., Durham, N. C.

Severe hypotension after administration of chlorpromazine is not common. Conventional doses may sometimes induce a moderate fall in blood pressure, but this is not usually sufficient to cause symptoms.[1] I have recently observed the sudden development of shock after administration of 10 mg. of prochlorperazine (Compazine) ethane disulfonate intramuscularly to a patient with a subsequently proved pheochromocytoma. This episode was followed by loss of function of the tumor. The purpose of this case report is to suggest that patients with pheochromocytomas may be unusually susceptible to the hypotensive effects of phenothiazine derivatives and that the occurrence of shock in this patient may have precipitated the degeneration of the tumor.

Report of a Case

An 18-year-old girl was admitted to Duke Hospital on July 25, 1958, for evaluation of recurrent abdominal pain. She had had headaches for six months, induced by exertion and relieved soon after lying down. Four weeks prior to admission she began to have recurrent attacks of generalized abdominal "pain" lasting about 30 minutes and often accompanied by vomiting. During the week preceding admission she had developed exertional dyspnea and orthopnea. Her health had previously been good. On physical examination her weight was 75 lb. (34 kg.); temperature, 101.4 F (38.6 C); pulse, 128 per minute; and blood pressure, 190/150 mm. Hg. The arterial pressure showed an orthostatic fall to 130/110 mm. Hg, and the pulse rate increased to 140. Her skin was pale and dry; the ocular fundi showed arteriolar spasm, venous compression, hemorrhages, and exudates. Neck veins were moderately distended. Examination of the heart revealed a loud split-second pulmonic sound; a harsh systolic murmur, accompanied by a thrill, was heard at the second left parasternal space. The liver was palpable just below the right costal margin. There was mild right costovertebral angle tenderness but no peripheral edema.

Laboratory studies on the blood showed hemoglobin level, 9.4 Gm. per 100 cc.; hematocrit value, 36%; red blood cells, hypochromic; white blood cells, 15,960 per cubic millimeter. Urine showed a trace of protein, a trace of sugar, and was otherwise normal. The fasting blood sugar level was 121 mg. per 100 cc. and the nonprotein nitrogen level 27 mg. per 100 cc. Urine and blood cultures showed no growth. The electrocardiogram showed isolated T-wave negativity from V_2 to V_4. X-ray studies showed that the heart was at the upper limits of normal in size and the lungs were clear. An intravenous urogram demonstrated prompt excretion of the dye, but the right kidney was displaced downward.

Hospital Course.—The patient remained febrile but felt well until the fourth hospital day when she suddenly developed severe abdominal cramps and vomiting. Four hours later 10 mg. of prochlorperazine was administered intramuscularly to allay her symptoms. The patient's blood pressure fell within 10 minutes from 190/150 to 80/60 mm. Hg, and she had the clinical appearance of shock. She was placed immediately in the Trendelenburg position and levarterenol (Levophed) bitartrate was administered by intravenous drip. After five hours her blood pressure had stabilized at 120/80 mm. Hg and the levarterenol was discontinued. During the next 24 hours her blood pressure rose to a new level of 160/120 mm. Hg. The abdomen remained diffusely tender and distended without guarding and intestinal sounds were hypoactive.

By the seventh hospital day, about 96 hours after its onset, abdominal pain had subsided and the patient tolerated oral feedings. Thereafter she had only minor attacks of "pain." Her temperature gradually declined to normal by the 13th hospital day, and the intensity of her cardiac murmur diminished. Her blood pressure, which had remained at 160/120 mm. Hg during her period of severe pain, slowly decreased to 100/70 mm. Hg by the 16th hospital day. Intravenous administration of 5 mg. of phentolamine (Regitine) hydrochloride on the 11th hospital day produced a fall in blood pressure from 166/120 to 98/62 mm. Hg within 2 minutes, with a return to pretest levels within 10 minutes.

Urinary catechol amines were measured in the laboratory of Dr. M. Goodall by a bioassay utilizing cat's blood pressure and hen's rectal cecum.[2] The fluorometric method of Von Euler and Floding[3] was also used. The significantly elevated values of the 7th and 13th hospital days fell to normal by the 21st day (see table). Seventy-two hours elapsed between the

---

From the Department of Medicine, Duke University Medical Center.

end of the levarterenol infusion and the beginning of the first urine collection. This time interval seems long enough to preclude the possibility that exogenous norepinephrine (noradrenalin) was being measured in the urine.[4]

After normotension had become established a hypertensive response could be provoked neither by the intravenous administration of 200 mg. of tetraethylammonium (Etamon) chloride or of 100 mcg. of histamine base nor by vigorous massage of the right flank.

*Urinary Catechol Determinations—Micrograms per 24 Hours**

41	17.9	29.5	3.2	31.8

* Average normal values [2]. epinephrine, 15.7; norepinephrine, 32.3

At laparotomy, on the 27th hospital day, a mass was found between the upper pole of the right kidney and the adrenal gland (see figure). This mass could be freed from the surrounding structures, but it was penetrated by the renal artery; consequently, the right kidney was excised after the renal artery was tied in removing the tumor. The adrenal gland was left intact. Throughout the procedure there was no significant change in blood pressure despite manipulation and removal of the tumor.

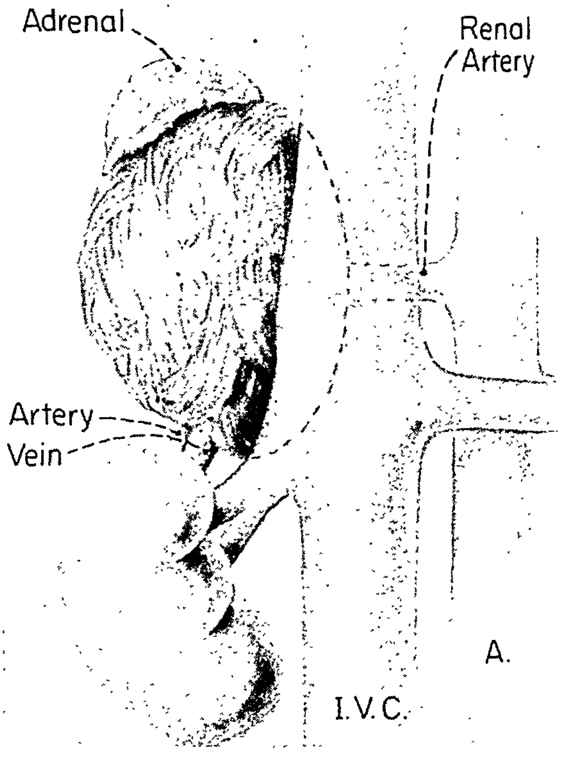
The patient's postoperative course was uneventful. She maintained a blood pressure of 110/80 mm. Hg and a pulse rate of 80 to 90 per minute, with orthostatic tachycardia. She felt entirely well on a return visit seven weeks after the operation, and her blood pressure was normal. Her eyegrounds showed complete resolution of the hemorrhages and exudates, and the arteriolar attenuation had disappeared.

Pathological Examination.—The gross specimen consisted of an encapsulated mass that weighed 5.4 oz. (153 Gm.) and measured 8 by 6.5 by 4 cm.; the capsule measured 7 mm. There was no connection with either the adrenal gland or the kidney. Cut section revealed that the tumor was yellowish brown, soft, and predominantly necrotic. Microscopic examination confirmed the impression of pheochromocytoma. There were no thrombi but the entire central mass was necrotic and had the appearance of an infarct. The infarcted area was organized from the periphery and among this fibrous tissue were small groups of chromaffin cells. Ghost-like cells in the necrotic center resembled these. The resected kidney appeared completely normal.

Comment

Phenothiazines and Shock.—The prompt development of shock in our patient after administration of prochlorperazine suggests that the drug precipitated her circulatory collapse. The pheochromocytoma may have predisposed her to this reaction or she may have been unusually sensitive to phenothiazines because of constitutional or other factors. An apparently normal individual rarely develops a marked fall in blood pressure in response to chlorpromazine.[1a] In our patient, however, another administration of 10 mg. of prochlorperazine intramuscularly seven weeks after the operation produced only a gradual, moderate decline in blood pressure without symptoms other than drowsiness, which made a constitutional basis for her severe hypotensive reaction appear unlikely. Hypertension itself does not seem to render a person more susceptible to shock induced by the phenothiazines. Stevenson and Sjoerdsma[5] studied the effect of intramuscular doses of 25 to 100 mg. of chlorpromazine in adults with benign essential hypertension and found no significant change in recumbent blood pressures.

On the other hand it seems that a patient with a pheochromocytoma, whose blood pressure is elevated by increased secretion of sympathetic amines, may be unusually sensitive to the hypotensive effects of the phenothiazines. There is much indirect evidence to support this view. Courvoisier and co-workers[6] found that chlorpromazine administered intravenously to dogs counteracted the pressor effect of infusions of norepinephrine and, to an even greater extent, of epinephrine (adrenalin). They stated that in large doses the effect of chlorpromazine resembled that of dibenzyl betachlorethylamine (Dibenamine) hydrochloride. Their animals were protected against a quantity of epinephrine equal to six times the lethal dose by the administration of 1 mg. of chlorpromazine per kilogram of body weight. Other studies have amply confirmed the adrenolytic properties of chlorpromazine.[7] Finkelstein and co-workers[8] showed that chlorpromazine in the fluid bathing an isolated heart muscle greatly reduced the positive inotropic action of epinephrine and norepinephrine.



Position of pheochromocytoma. Dotted lines show penetration by renal artery.

Although the adrenolytic effect of chlorpromazine might be the primary factor in causing a drop in the blood pressure of a patient with a tumor producing sympathetic amines, this response might be intensified by some of the other pharmacological actions of chlorpromazine, including depression of the vasomotor center,[9] ganglionic blockade,[10] and direct peripheral vasodilatation.[11]

A survey of the literature reveals only one description of a case of hypertension associated with pheochromocytoma in which the effect of administration of a phenothiazine derivative is discussed. Lima and co-workers[12] reported a patient in Brazil with a pheochromocytoma to whom 25 mg. of chlorpromazine was given intramuscularly for sedation during a hypertensive crisis. The blood pressure fell from 280/160 to 70/30 mm. Hg and a vasopressor agent was required. During subsequent paroxysms the administration of chlorpromazine was invariably followed by a prompt hypotensive response. When therapy was maintained with prophylactic oral doses of chlorpromazine the hypertensive crises became less frequent and intense.

The symptomatology often associated with a hypertensive paroxysm may prompt the physician to administer one of the phenothiazine analogs, or the symptoms may be interpreted as an acute anxiety syndrome requiring a tranquilizer. The diagnosis of pheochromocytoma should be considered if a severe hypotensive response follows the administration of the drug.

Pheochromocytoma and Shock.—Another feature of interest in this case is the apparent association of the hypotensive reaction to the degeneration of the tumor. The development of shock in a patient with a pheochromocytoma before surgical excision has been described.[13] In many of these instances the tumor appeared degenerated at operation or autopsy, and the peripheral vascular collapse was attributed to the destruction of the tumor with abrupt cessation of pressor hormone output.[14] In the case here presented it seems possible that the sudden development of shock was responsible for initiating or accelerating infarction of the tumor and that generalized circulatory failure was thus the cause of tumor necrosis rather than its consequence.

It is conceivable that some degree of local vasoconstriction is present within a tumor containing large quantities of norepinephrine. Hence the tumor, with its great metabolic demand, may suffer chronically from a relative deficiency of blood supply. The cystic and necrotic areas frequently seen on pathological examination of actively functioning pheochromocytomas[15] may be a reflection of this state. The sudden superimposition of generalized circulatory failure may then precipitate massive infarction in the already ischemic tissue, leading to progressive loss of its highly specialized function.

The sequence of events here proposed has not been considered in the available case reports of shock occurring in patients with pheochromocytoma. It is conceivable that drugs were the real cause of shock in some of these patients or that their shock was similar to the circulatory failure observed in animals infused with large doses of epinephrine.[16] However the shock was produced, the necrosis of the tumor may have been merely a secondary phenomenon.

The evidence for tumor degeneration in our patient rests not only on the profound morphologic changes but also on the disappearance of hypertension, the negative responses to the provocative tests, the decline to normal of the urinary catechol amine levels, the absence of a hypertensive response during manipulation of the tumor at surgery, and finally on the stability of the blood pressure after removal of the tumor. The functioning pheochromocytoma had become converted into a physiologically inactive mass, rendering the patient asymptomatic before surgical intervention. A similar demonstration of loss of function of a pheochromocytoma was not found in the literature.

Summary

In a case of pheochromocytoma the administration of prochlorperazine was followed by generalized circulatory failure and then by loss of tumor function, documented by successive catechol amine determinations. Patients with pheochromocytomas may be extraordinarily sensitive to the phenothiazine drugs, and shock after their administration might point to the diagnosis of pheochromocytoma when the clinical picture is otherwise unclear. It is suggested that an episode of shock may play a significant role in promoting necrosis of a pheochromocytoma.

The catechol amine determinations were made by Dr. M. Goodall and the pathological examination by Dr. Bernard F. Fetter. The operation was performed by Dr. George J. D'Angelo.

ACUTE ALLERGIC COLITIS PRESENTING THE CLINICAL PICTURE OF ACUTE APPENDICITIS

REPORT OF A CASE

Harold L. Karpman, M.D., Boston

This case report describes the effect of parenterally given epinephrine on colonic lesions in a case of acute colitis presenting the clinical picture of acute appendicitis.

A 47-year-old woman entered Beth Israel Hospital, Boston, on Sept. 1, 1955, with the chief complaint of abdominal pain of 24 hours' duration. The patient had been in good health until the evening before admission when, while sitting quietly, she noted the gradual onset of lower abdominal pain which became severe enough to cause fainting. The pain diminished somewhat but recurred; an analgesic was given subcutaneously for relief. The pain was described as cramping in nature with occasional severe exacerbations felt throughout the lower part of the abdomen. Between these exacerbations the patient noted a persistent ache in the lower part of the abdomen. She also experienced mild diarrhea. On the night prior to admission the patient had eaten lobster for dinner, as did several members of her family (no other members of the family were ill). Her history and a systemic review were completely negative except that the diagnosis of allergic rhinitis had been made in 1938.

Physical examination revealed a slightly obese, alert, cooperative female in no acute distress. Her pulse, respirations, and blood pressure were within normal limits, and the oral temperature was 99 F (37.2 C). Physical examination gave normal findings except for the presence of deep, right lower quadrant abdominal tenderness which could be demonstrated only with the patient in the right lateral decubitus position. Urinalysis revealed 1+ albuminuria. The white blood cell count was 19,600 per cubic millimeter. The diagnosis of acute appendicitis was made, and the patient was taken to the operating room.

At operation, performed by Dr. L. Hermansen, the cecum and transverse colon appeared normal, as did the sigmoid colon. However, a 12-cm. segment of the upper portion of the descending colon was involved in a bizarre reaction which ended abruptly at the junction of the descending colon and the sigmoid flexure; the entire intestinal wall was thickened and edematous but not discolored. Along the mesenteric borders of the intestine were numerous large bullae containing a clear fluid which was seen to extrude through the intestinal wall. The process resembled a local sensitivity phenomenon. Apparently the mesecolon and the adjacent peritoneum were not involved.

Biopsy was not deemed advisable. All fluid was aspirated from the bullae and 0.3 cc. of a 1:1,000 solution of epinephrine (Adrenalin) was administered parenterally with prompt partial regression of the process. Incidental appendectomy was performed, and the abdomen was closed in layers without drainage.

The postoperative course was benign, and the patient was discharged from the hospital on the sixth postoperative day. White blood cell counts prior to discharge from the hospital were normal and eosinophils were not present either in a differential smear or in an eosinophil count. Culture of the peritoneal fluid revealed no growth. The gross and microscopic examination of the appendix revealed a normal appendix. Routine scratch tests at the allergy clinic all gave negative results.

Assistant Resident in Medicine, Beth Israel Hospital. Dr. Karpman is now Instructor in Medicine, Department of Medicine (Cardiology), University of Southern California, Los Angeles.

Comment

Although mortality and morbidity from appendectomy have been reduced to extremely low levels,[1] there are many patients in whom it would be most desirable to avoid operation. In these patients one should use all available diagnostic techniques before scheduling even a "benign" surgical procedure. This report demonstrates the effect of epinephrine on acute bullous lesions of the serosal surface of the descending colon. As would be expected if the condition were allergic, these lesions regressed within minutes after the subcutaneous injection of epinephrine. It is, of course, impossible to correlate definitely the presence of these lesions with the clinical picture preoperatively, as it is also impossible to correlate the presence or absence ot these lesions with the lack of symptoms postoperatively. One can say only that (1) the only intra-abdominal pathology found at laparotomy were these bullous lesions, (2) the appendix was normal histologically, (3) these lesions regressed rapidly after epinephrine was given parenterally, (4) the patient had no symptoms postoperatively, and (5) the patient had a definite allergic history in the past. The clinical syndrome apparently was due, therefore, to some vague allergic factor which produced the bullous lesions and which was counteracted by parenterally administered epinephrine.

Allergic symptoms of the gastrointestinal tract have been reviewed extensively by Withers,[2] Andresen,[3] and Miller.[4] Andresen [5] describes three types of colonic syndromes which apparently have an allergic component: a mild reaction commonly called "mucous colitis" or "irritable colon"; a more severe reaction which he terms "colon spasm" or "colitis"; and a very severe reaction simulating intestinal obstruction, acute inflammation, or perforation. Andresen notes that in the very acute phase of the severe reaction ephinephrine chloride, 1 cc. or less of a 1:1,000 solution, will afford immediate and almost miraculous relief of symptoms. Eusterman [6] describes a patient with recurrent painful gastrointestinal allergy in whom subcutaneous injection of epinephrine relieved symptoms within 20 minutes. Merrill,[7] too, notes that epinephrine often is useful in treating gastrointestinal allergy. He describes a patient with acute abdominal distress who received epinephrine to combat initial shock with a lessening of her abdominal symptoms; subsequent laparotomy revealed changes in the terminal ileum and cecum which supported a diagnosis of allergy.

Although epinephrine or ephedrine sulfate administered subcutaneously or atropine given orally may relax allergic spasm and aid in differential diagnosis, Ratner [8] cautions that surgical intervention may be imperative despite an allergic component: a too pronounced or prolonged allergic reaction may develop into a condition amenable only to operation. Therefore, even in the face of an allergic background, if the signs resemble appendicitis or intussusception, surgical intervention may be imperative.

Had epinephrine been administered prophylactically, it is quite possible that in the patient reported here the symptoms would have disappeared or at least abated in much the same manner as the intestinal lesions did. Therefore, one might suggest a therapeutic trial with parenterally given epinephrine in patients presenting a clinical picture of acute appendicitis where a history of allergic disorder is present and especially where it would be desirable to avoid operation. The epinephrine should be given immediately and the patient observed closely while preparations for operation are in progress; then, if operation is required it need not be delayed.

A note of caution regarding the use of epinephrine: Needless to say, epinephrine should not be used in anyone in whom a specific contraindication for its use exists, but, equally important, the administration of epinephrine should not lull the physician into a false sense of security even if the signs and symptoms abate. The patient should be watched closely for a reasonable period of time so that any evidence of persistence or recurrence of symptoms may be detected immediately and appropriate steps taken before serious complications occur.

Summary

In a patient, bullous lesions of the serosal surface of the descending colon (presumably allergic in nature) regressed after the parenteral administration of epinephrine. A preoperative diagnostic test with parenterally given epinephrine may be done in such patients. This test will be of help in the differentiation of acute appendicitis from acute allergic colitis, and it should also reduce the frequency of unnecessary laparotomies.

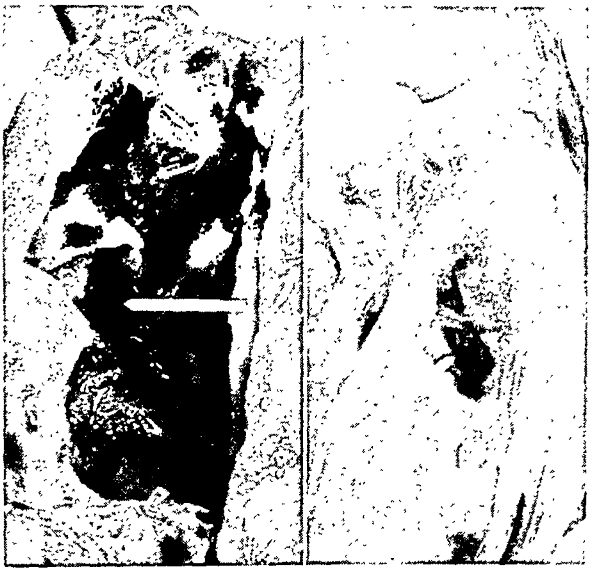
SPONTANEOUS RUPTURE OF AN ABDOMINAL AORTIC ANEURYSM INTO THE INFERIOR VENA CAVA

REPORT OF A CASE

Seymour M. Greenstone, M.D., Theodore Massell, M.D.
and
E. Craig Heringman, M.D., Sherman Oaks, Calif.

Although sporadic reports of arteriovenous fistulas between the aorta and inferior vena cava have been noted in the literature, these were the results of trauma, usually a gunshot wound. The spontaneous rupture of an abdominal aortic aneurysm into the inferior vena cava is a rare occurrence. Viar and Lombardo[1] reported in 1952 what they believed to be the first case. Their patient survived about six weeks after the development of such a spontaneous fistula, manifesting signs of severe progressive right heart failure, unresponsive to all medical therapy. Autopsy revealed a 13-cm. aortic aneurysm with a 1-cm. opening into the inferior vena cava.



Left, opening in arteriosclerotic aneurysm, revealing large fistula into inferior vena cava. *Right*, opening in inferior vena cava, revealing arteriovenous fistula.

More recently, Eiseman and Hughes[2] and Shumacker and Jontz[3] each described successful resection of an abdominal aortic aneurysm which had ruptured into the inferior vena cava and the replacement with a graft after closure of the caval defect. Both patients manifested severe cardiac failure, massive peripheral edema, widened pulse pressures, and pulsating abdominal masses with loud bruits. A case report describing some of the findings associated with this vascular catastrophe is given below.

A 69-year-old man, who had not been under prior medical care, was admitted on Nov. 23, 1956, with a six-hour history of severe abdominal pain followed by shock. Examination revealed an acutely ill elderly man with marked dyspnea and shallow respirations, pulse rate 120 per minute, and blood pressure 80/30 mm. Hg. The skin was cold and wet. Heart and lungs were within normal limits. A pulsating mass was present in the mid-abdomen and was associated with a to-and-fro murmur in this region and also along the vertebral spines posteriorly in the lumbar region. The pedal pulses were normal. Initial hemoglobin level was 13.1 Gm.%; his blood type was A positive. The initial impression was that a leaking abdominal aortic aneurysm was present. Emergency treatment consisted of nasally given oxygen and the infusion of 2 units of blood. The skin became warm and dry, but the rapid pulse and low blood pressure persisted. About three hours after admission he was taken to the operating room. During the induction of anesthesia he developed cardiac arrest. The left side of the chest was opened immediately through the fourth intercostal space, and cardiac massage was instituted. The heart developed ventricular fibrillation which was successfully defibrillated with the electric defibrillator. Cardiac massage was continued, but a satisfactory cardiac rhythm could not be reestablished.

Autopsy revealed a large fusiform aneurysm of the abdominal aorta arising about 2 cm. beyond the origin of the renal arteries. The aneurysm measured 10 cm. in diameter, and it extended downward to the bifurcation (see figure). The aneurysm was partially filled with pale, yellow-tan, laminated thrombus measuring up to 3 cm. in thickness. This thrombotic layer was thinnest in the right posterior portion adjacent to the vena cava. In the center of this area the thrombus was eroded, and the attenuated aneurysm wall had ruptured through the wall of the inferior vena cava, producing an arteriovenous fistula which measured slightly more than 2 cm. in its greatest diameter. There was no evidence of rupture into the retroperitoneal space. The other regions of the aorta showed considerable arteriosclerotic changes in the ascending portion, arch, and major branches. The coronary arteries also showed extensive arteriosclerosis with calcification but no serious impairment of the lumen. The remainder of the autopsy showed essentially normal findings.

Microscopic examination of the aorta in the region of the fistula revealed extensive infiltration of the wall of the aorta and the inferior vena cava with lymphocytes and plasma cells. The walls of both the aorta and the vena cava were markedly attenuated and showed fresh hemorrhage splitting the vessel walls.

Comment

The classic signs of an arteriovenous fistula with right heart failure—widened pulse pressure, peripheral edema, venous distention, enlarged liver—were not apparent in this case due to the rapidity of onset and the large diameter of the fistula. The to-and-fro murmur over the aneurysm and lumbar region was the only objective finding, and its significance was not recognized at the time. Holman[4] has stated that it is an experimentally observed fact that, when a fistula is established between the aorta and vena cava 1-1.5 cm. in diameter, it is invariably fatal. It would appear that the smaller fistulas and those that develop gradually increase the cardiac return at a rate slow enough to allow initial compensation and, finally, the findings of right heart failure. Large fistulas that develop rapidly, such as is reported here, throw such a large burden on the heart that rapid cardiac failure or cardiac arrest is more likely.

Since the inferior vena cava is so closely applied to the aorta and since it is involved in the nonspecific inflammatory reaction that is so characteristic of arteriosclerotic aneurysms, it is interesting that more complications such as this have not been observed. The usual course is leakage into the retroperitoneal space with secondary rupture into the free peritoneal space. Rupture into the duodenum and other portions of the intestine is observed less frequently. With the progressively increasing number of aged persons in our population, more arteriosclerotic aneurysms will be encountered; the possibility of a fistula into the inferior vena cava should be considered in those persons who develop intractable right-sided cardiac failure.

Summary

In a patient with spontaneous rupture of an arteriosclerotic abdominal aortic aneurysm into the inferior vena cava, the fistula developed rapidly, was of large diameter, and precipitated cardiac arrest. Patients with smaller fistulas are more likely to develop intractable right heart failure and this should be considered in the differential diagnosis of this condition. Treatment should consist of resection of the aneurysm, replacement with a graft, and closure of the fistula into the inferior vena cava.

DIABETIC NEUROPATHY PRECIPITATED BY DIABETIC CONTROL WITH TOLBUTAMIDE

Max Ellenberg, M.D., New York

Tolbutamide (Orinase), a sulfonylurea derivative, is an orally given hypoglycemic agent which has recently been added to the therapy of diabetes mellitus. The introduction of any new drug into the therapeutic armamentarium necessarily requires careful observation to detect any toxic manifestations. This applies even more to tolbutamide, since, in addition to being a new drug, it is chemically related to the sulfonamides which have many known undesirable side-effects, the site and mode of action are not clearly defined, its use requires a prolonged period of administration, and it is a substitute for insulin, a known nontoxic agent which has been used safely and successfully for the past 25 years. On the other hand, it is equally important not to attribute to a drug undesirable but coincidental clinical phenomena that are inherent in the course of the disease under treatment and, hence, unrelated to any injurious effects of the medicament per se.

To date, tolbutamide seems to have proved its clinical effectiveness and in many situations has facilitated the control of diabetes. So far, there have been remarkably few reactions and virtually none of any serious nature. Observed side-effects include relatively few hematological reactions, dermatological manifestations, gastrointestinal symptoms, and, more rarely, such ill-defined accompaniments as malaise, headache, weakness, and paresthesias.[1] A case of nephrosis during tolbutamide administration has been reported,[2] but its coincidental association has not been ruled out nor have any similar instances been recorded.

No previous reports of neurological complications have appeared in the literature. The following case reports are presented as instances of diabetic neuropathy after the use of tolbutamide to control the diabetes. It is the aim of this paper to indicate that the neuropathy is not a toxic manifestation of the drug but, rather, it has been precipitated or severely

---

From the Department of Medicine, Mount Sinai Hospital.

exacerbated after the institution of good control and while the patients' diabetes remained under good control.

Report of Cases

CASE 1.—On her first Mount Sinai Hospital admission, a 47-year-old woman had the chief complaint of pain in the right armpit, right upper part of the chest, and left lower extremity. The patient's diabetes was discovered five years before, when she visited a physician for weight-reducing instruction. At this time she was obese, weighing 230 lb. (104.3 kg.). Since then, she has lost 120 lb. (54.5 kg.)–100 lb. (45.4 kg.) up until six months before the present admission and another 20 lb. (9.1 kg.) since the onset of the present illness. During this five-year period she tested her urine about once a month, always detecting glycosuria but never having it treated. Six months prior to admission, in the course of a medical examination, glycosuria was again noted and hyperglycemia (blood sugar level 288 mg.%) was documented.

In view of the long-standing untreated diabetes and persistent weight loss, specific therapy in the form of tolbutamide was instituted. The patient received 1 Gm. a day. Fourteen days later she experienced the sudden onset of severe burning pain in the right scapular area radiating into the right axilla and the right breast. Two weeks after this, she noted tingling pain and paresthesias beginning in the left buttock which radiated down the lateral aspect of the left lower extremity to the midthigh. The pains were persistent, severe, and always worse at night and were relieved only by large amounts of narcotics, salicylates, and tranquilizers in combination. There was progressive weakness of both lower extremities, of the left more than of the right, with an accompanying sensation of numbness "as though my feet were no longer part of me." In association with these symptoms, the patient, although usually a jovial person, became depressed and developed anorexia. The patient was given 1,000 mcg. of vitamin B_{12} parenterally daily for three months. Because of the persistence of symptoms and their association with the administration of tolbutamide, the drug was withdrawn after four months. Nevertheless, the symptoms continued unabated.

Her history included total hysterectomy at the age of 23 years for fibroid tumors. The family history revealed the presence of diabetes in her mother, father, and two paternal aunts, one of whom had an amputation of an extremity for diabetic gangrene.

Physical examination revealed a middle-aged woman complaining of pain. Weight loss was evident. Examination of the fundi revealed pinpoint hemorrhages and exudates. Heart and lungs were normal; blood pressure was 130/80 mm. Hg; and the liver was palpable one fingerbreadth below the costal margin. Neurological examination revealed slow cautious gait, difficulty in arising from a squatting position, weakness of flexion at the hips and both knees, absent knee jerks and ankle jerks, hyperalgesia over the right upper thoracic segments T-7 to T-10 and on the left between S-1 and S-3, and decreased vibratory sensation over all the toes. The pupils were unequal and irregular and reacted poorly to light.

Laboratory investigation revealed a normal blood cell count, a trace of albumin in the urine, glycosuria of 1 to 4+, blood urea nitrogen level 13 mg.%, cholesterol level 345 mg.%, alkaline phosphatase level 6.8 King-Armstrong units, sedimentation rate 4 mm. per hour; blood Wassermann test result negative, and fasting blood sugar level 230 mg.%. X-ray of the chest and thoracolumbosacral spine showed normal findings. Lumbar puncture revealed clear fluid under normal pressure with normal manometric reading, cell count, and Wassermann and colloidal gold test results; the total protein level was elevated to 90 mg.%.

In view of the uncontrolled diabetes, the patient was started on tolbutamide therapy, 2 Gm. per day. This dosage was soon reduced to 1 Gm. a day and has been maintained uninterruptedly. While she was in the hospital, her symptoms started to abate and have progressively improved.

The symptoms, signs, elevated spinal fluid protein level, and course in this case were entirely compatible with diabetic neuropathy. Although tolbutamide was suspected as being a toxic agent for the radiculoneuropathy, the course was unaffected by withdrawal of the drug and later by reinstitution of the medication. In fact, the improvement started while she was receiving tolbutamide and continued progressively during maintenance of this therapy.

CASE 2.—A 70-year-old woman had been carefully observed for the possible occurrence of diabetes for many years since her mother, each of her five sisters, and both brothers were known diabetics; two of them had died after amputation for diabetic gangrene. One month ago, she developed pruritus vulvae accompanied by mild polyuria and polydipsia but no weight loss. She quickly recognized the potential significance of these symptoms and instituted dietary restrictions but achieved little success. She therefore presented herself for more specific therapy. There were no complaints referable to the extremities, nor were there any sphincter disturbances. Her history included several attacks of cholelithiasis without jaundice.

On examination the pupils were normal, fundi showed no hemorrhages or exudates, heart and lungs were normal, blood pressure was 160/100 mm. Hg, the liver edge was palpable, and the peripheral pulses were palpable. Neurological examination, including tests of all reflexes and sensory modalities, showed entirely normal findings.

Laboratory examination revealed a normal blood cell count, blood urea nitrogen level 19 mg.%, cholesterol level 254 mg.%, blood Wassermann test result negative, electrocardiogram normal except for left axis deviation, fasting blood sugar level 184 mg.%, and urine normal except for a 2+ glycosuria.

The patient was given 2 Gm. of tolbutamide daily and a diet with 150 Gm. of carbohydrate, 80 Gm. of protein, and 80 Gm. of fat. Within one week she showed definite improvement: the fasting blood sugar level fell to 128 mg.% and the pruritus cleared considerably. The dosage of tolbutamide was reduced to 1 Gm. daily given before breakfast. Three weeks after starting treatment with tolbutamide and diet, the patient complained of numbness in the feet, more marked on the left than on the right and increased at night. The fasting blood sugar level at this time was 150 mg.%. Because of aglycosuria, the dosage of tolbutamide was lowered to 0.5 Gm. daily. However, the numbness continued to become increasingly severe. In addition, the patient now stated that her feet felt cold and "lifeless." At this time, the neurological examination revealed absent ankle jerks with depression of the knee jerk. There was stocking distribution of diminished light touch and vibratory sensations in both feet. Further observation of the patient revealed good control of the diabetes on the therapy with one tablet (0.5 Gm.) of tolbutamide daily. Although the drug was never withdrawn, the symptoms began to disappear two months after onset and were completely gone five months after institution of therapy.

The initial course of this patient seems to relate the neuropathy to the tolbutamide. However, the subsequent course, during which the neuropathy cleared despite continued medication, clearly puts this case into the category of neuropathy after institution of good diabetic control.

CASE 3.—A 72-year-old man had developed diabetes 15 years before. His symptoms at that time consisted of polyuria, polydipsia, and weight loss. He was treated with diet and insulin until four years before the present illness, when his physician died. Since then there had been no observation of his diabetic status. Although he continued to take 15 units of protamine zinc insulin daily, there was slow but steady, progressive weight loss of 20 lb. accompanied by polyuria, nocturia, and dryness of the mouth. He finally consulted a physician, who found uncontrolled diabetes and started the patient on tolbutamide therapy. The patient soon began to feel much better; polyuria, nocturia, and dryness of the mouth disappeared and he began to gain weight. However, four weeks after starting to take the drug, he developed a severe headache in the right temporofrontal area which was followed in five days by diplopia and inability to open his right eye.

Examination at this time revealed a complete ophthalmoplegia on the right. In addition, there was neuropathy involving the lower extremities manifested by absent knee jerks, absent ankle jerks, and absent vibratory sensation below the iliac crests. The blood pressure was 190/100 mm. Hg, urine showed 4+ albuminuria, the fundi did not reveal any hemorrhages or exudates, x-ray of the skull showed normal bones without evidence of injury or increased intracranial pressure, and the edrophonium (Tensilon) chloride test showed negative findings. The diabetes remained well controlled on 1.5 Gm. of tolbutamide, and this dosage was continued without interruption. With no other therapy, the oculomotor paralysis started to clear spontaneously in about one month and disappeared entirely over the course of the next three months.

This case illustrates the occurrence of extraocular muscle paralysis shortly after the institution of good diabetic control with tolbutamide and with complete disappearance of the involvement despite the continued use of the drug. The premonitory severe headache corresponding to the distribution of the first portion of the trigeminal nerve, followed by the nerve paralysis, the complete spontaneous resolution, and the absence of any other neurological disease is entirely compatible with the usual picture and course of extraocular nerve paralysis occurring in patients with diabetes.

Comment

The precipitation or exacerbation of diabetic neuropathy after the institution of control of diabetes has been previously recorded.[3] Recently, this sequence of events has been stressed with emphasis on the fact that the control of the diabetes is the factor involved.[4] Regardless of the means of achieving control, similar results have been noted. For example, although originally referred to in the literature as "insulin neuritis," the neuropathy may occur under comparable circumstances after the control of the diabetes by diet alone.[5] The arguments presented to establish this sequence of events with insulin include these statements: 1. The clinical picture, findings, and course were identical with all other forms of diabetic neuropathy. 2. The neurological syndrome cleared even though insulin administration was continued. 3. The same phenomena have been observed with diabetic control by diet.[4]

The same considerations apply to the case reports presented here. The neurological syndrome in each instance conformed to the accepted criteria of diabetic neuropathy, and the course was compatible with known experience. Above all, the manifestations cleared even though the administration of tolbutamide was maintained. In fact, in case 1, the tolbutamide therapy was reintroduced with no untoward effects; if the neuropathy were a toxic manifestation of the drug, then one would have expected this reintroduction to act as a "challenge" dose. Hence, it may be concluded that the tolbutamide is not the noxious agent but merely acts as the medium for control of the diabetes which in turn, in certain instances, leads to neuropathy. In the same vein, one may confidently predict that, with the forthcoming introduction of other orally given hypoglycemic agents, similar instances of neuropathy after control of diabetes will be encountered.

The etiology and mode of onset of diabetic neuropathy, along with many other factors, remain obscure.[6] It is possible that the relatively sudden change of the homeostasis may produce the equivalent of a stress phenomenon and thus precipitate the neuropathy. This suggestion stems from the observation that other stress phenomena, such as surgery, trauma, and infection, have been known to immediately precede the onset of neuropathy in the diabetic patient.

Summary

In three patients, the onset of diabetic neuropathy followed the institution of control of hyperglycemia and glycosuria with tolbutamide. Although this drug was suspected as being a toxic etiological agent, several factors absolve it of this role: The neuropathy in these circumstances was identical with the recognized forms of diabetic neuropathy, including symptoms, signs, and course; the neurological picture improved and symptoms disappeared despite the continued use of tolbutamide; and similar experiences have been reported with control of diabetes by insulin or dietary restrictions. Thus, tolbutamide is not the noxious agent but acts as the medium for control of the diabetes which, in certain instances, leads to neuropathy.

SPONTANEOUS REGRESSION OF MALIGNANT DISEASE

GUEST EDITORIAL

Tilden C. Everson, M.D.
and
Warren H. Cole, M.D.

FOR DECADES the reported disappearance or regression of malignant tumors, without significant therapy to explain it, has intrigued the profession, and has given rise to controversy as to whether or not the phenomenon actually exists. Spontaneous regression of cancer may be defined as the partial or complete disappearance of a malignant tumor in the absence of all treatment or in the presence of therapy which is considered inadequate to exert a significant influence on the growth of neoplastic disease. Indeed, spontaneous regression is a somewhat inaccurate term for this phenomenon because any change in the growth pattern of malignant tissue must have a biological explanation.

Efforts to find an explanation of this phenomenon have been thwarted by the fact that, fortunately, only a small fraction of patients with malignant disease go untreated. Thus, spontaneous regression of cancer has been mainly reported in patients in whom the cancer was beyond the scope of cure by the accepted techniques of surgery and/or radiation.

To help find an answer to this phenomenon we have studied the hundreds of cases which have been reported in the world literature since 1900 as examples of spontaneous regression of cancer, and have solicited unpublished reports of cases from our medical and surgical colleagues. The majority of the published cases have been too poorly documented to be considered as valid examples. Most frequently microscopic diagnosis of the malignancy has been lacking.

Of the entire group of cases reported, or made available by our medical friends, we have collected 112 cases which appear to have adequate documentation (including histological diagnosis of the malignancy) to be acceptable as probable examples of spontaneous regression of cancer. This phenomenon was reported most commonly in neuroblastoma (25 cases), choriocarcinoma (14 cases), carcinoma of the kidney (11 cases), malignant melanoma (10 cases), soft-tissue sarcoma (9 cases), and carcinoma of the bladder (7 cases). Spontaneous regression was more rarely reported in the commonly occurring cancers such as carcinoma of the breast (5 cases), carcinoma of the stomach (3 cases), cancer of the colon and rectum (3 cases), and carcinoma of the uterus (3 cases).

The regressions in these collected cases have been divided into two general types: (1) regression of the primary tumor and (2) regression of metastases. In some of the patients with regression of metastases, microscopic confirmation of the metastases is lacking, although in every case microscopic diagnosis of the primary lesion is available. Clinical and x-ray examinations have been the basis of diagnosis of the unconfirmed metastases.

In looking for an explanation of the spontaneous regression of cancer the first consideration is that the original histological diagnosis of cancer may have been incorrect. However, in 67 of the 112 cases tissue slides or photomicrographs have been available for review. Clinical and experimental knowledge indicates the probable importance of endocrine factors in at least some spontaneous regressions of choriocarcinoma, carcinoma of the kidney, malignant melanoma, malignant teratoma, carcinoma of the ovary, and carcinoma of the breast. An impairment of the blood supply appears to be a possible explanation, particularly in the neuroblastomas, since some of these were partially removed at operation and the remaining portion traumatized by the attempt to remove it. Most of the patients with regression of a bladder tumor had had diversion of the urine by transplantation of the ureters. In these cases it would seem that a carcinogenic agent in the urine was necessary for the development and continued growth of the tumor. Fever and/or infection may be implicated as the cause of spontaneous regression in several cases.

Although our study has led us to the conclusion that spontaneous regression of malignant tumors may occur on very rare occasions, we are unable to offer a figure as to its true incidence. This inability to establish a figure of incidence is partly related to the fact that we have no way of knowing how many patients are alive or dead without treatment. We believe the phenomenon is very rare, but it is barely possible that a few of the good results after therapy are related to spontaneous regression.

From the Department of Surgery, University of Illinois College of Medicine, Chicago.

The probability of spontaneous regression occurring in any single case of cancer is so extremely small, however, that any patient would be most foolish to reject orthodox methods of treatment in the hope that his cancer would regress spontaneously.

Evidence of the occurrence of spontaneous regression of cancer supports the concept of biological control of cancer and reinforces the hope that more satisfactory methods of treating cancer than surgery and/or radiation may be found in future years. Also, the occurrence of spontaneous regression of cancer demonstrates the need for caution in the assessment of the value of chemotherapeutic and unorthodox therapeutic measures in isolated "cures" of cancer.

The remote possibility of spontaneous regression of cancer may be of some psychotherapeutic value in offering hope to patients and relatives of patients with "incurable" cancer. Often, indeed, the mere thought that regression might possibly take place changes their attitude from that of complete despair to that of hopeful toleration. The profession should use knowledge of this phenomenon, rare as it is, in an endeavor to comfort the patient and his relatives in the trying days of terminal cancer. With proper precaution the physician can do this without being guilty of offering false hopes.

NATIONAL CANCER INSTITUTE STUDY OF KREBIOZEN

The American Cancer Society statement dated March 9, 1959, which appears in this issue of The Journal, page 1790, urged that the Krebiozen Research Foundation accept the proposal of the National Cancer Institute of the U. S. Public Health Service to test the controversial cancer substance, Krebiozen, in "a manner acceptable to the scientific community." This statement reviews the history of Krebiozen; it clarifies the issues and presents the society's position regarding it.

Since the Krebiozen Research Foundation, its spokesmen, and advocates have "long claimed they have a useful tool against cancer," the American Cancer Society indicated that "it is then their clear duty to thousands of cancer patients to cooperate with the National Cancer Institute or any group of competent, objective scientists in an objective test of the drug." Furthermore, the society indicated that the "delays" which have recently been given so much publicity by the Krebiozen Foundation "are now clearly the responsibility" of that foundation.

The American Medical Association concurs with the American Cancer Society that the prolonged and continued agitation associated with the Krebiozen controversy has a disturbing and unsettling effect on many cancer patients as well as on their relatives and friends, who are bewildered and wonder whether or not the many extraordinary claims made for Krebiozen are actually true.

In 1952 the Committee on Research of the Council on Pharmacy and Chemistry of the American Medical Association published a lengthy report which did not support the contentions of the promoters of the substance at that time. A Committee on Cancer Diagnosis and Therapy of the National Research Council came to essentially the same conclusions. A committee of six distinguished physicians from several medical schools, headed by Dr. Warren H. Cole, reviewed 500 cases of cancer treated with "Krebiozen" and came up with a number of conclusions, including: "Ignorance of the material interferes with a sound evaluation of its therapeutic effectiveness. . . . no acceptable evidence that any malignant tumor had been cured by Krebiozen. . . . no evidence of prolongation of life. . . . no histological evidence that Krebiozen produced degenerative or regressive changes in tumor cells."

Even though no convincing scientific evidence has been presented during the intervening eight years since the substance was announced, the American Medical Association is currently of the opinion that it is in the public interest that this controversy be terminated. It is in complete agreement with the American Cancer Society that this can be accomplished only through the medium of a thoroughly objective study such as that which the National Cancer Institute has indicated it is prepared to undertake.

Sound research in medicine calls for precise chemical and biological studies, for extensive work on animals, for sustained work in recognized laboratory and clinics, for prior publication in technical journals, for criticism, and for the encouragement of like technical studies elsewhere. These are the proper channels for scientific evaluation of any drug or substance and there is no logical reason why they cannot be followed with Krebiozen.

The American Medical Association, along with the American Cancer Society and, it is believed, with the concurrence of all other scientific organizations expresses the hope that the Krebiozen Research Foundation will recognize the integrity of the National Cancer Institute of the U. S. Public Health Service and proceed to cooperate with this agency that is endeavoring to scientifically evaluate actual and alleged cancer therapy. The American Medical Association believes that in this way the public interest would best be served.

The Krebiozen Research Foundation should desist in its demands for an evaluation of the efficacy of Krebiozen dictated according to its own terms, rules, and procedures which are contrary to the soundly established scientific approaches utilized in the evaluation of substances alleged to be of therapeutic value in malignant disease.

If the representations of the owners and promoters of Krebiozen possess any degree of validity there is nothing to lose and much to gain from such an objective analysis. Failure to accede to such an objective evaluation can be interpreted as an expression of fear or doubt concerning the results of removal of the secrecy which has persistently shrouded Krebiozen through the eight years of its promotion.

ORGANIZATION SECTION

STATEMENT TO SENATE ARMED SERVICES COMMITTEE ON H. R. 2260

March 2, 1959

The Honorable Richard B. Russell, Chairman
Committee on Armed Services
U. S. Senate
Washington 25, D. C.

Dear Chairman Russell:

The purpose of this letter is to submit for the consideration of the Committee on Armed Services the position of the American Medical Association on H. R. 2260, 86th Congress, a bill, which, in part, would extend until July 1, 1963, the induction provisions of the Universal Military Training and Service Act.

With respect to the extension of the special provisions of this Act applicable to medical, dental, or allied specialists, the American Medical Association wishes to reaffirm its position which was outlined in testimony presented in 1957, on the bill which subsequently was enacted as Public Law 85-62, approved June 27, 1957. At that time, the Association testified that, ". . . if the demands for the defense and security of our nation are such that, in the opinion of Congress, it is necessary to have a draft act to maintain the strength of our Armed Forces, then the extension of the present legislation would be one method to insure sufficient physicians for the military services."

The Association also recommended retention of the provisions of the law relating to the national, state and local committees which advise the Selective Service System in regard to the selection of medical, dental and allied specialists required by the services. These advisory committees consider, among other factors, the needs of the civilian population in the communities from which these physicians would be taken. The Association is pleased that this provision is a part of the current law.

In regard to specialist categories, the Association recommends, as it did previously in May, 1957, that the word "other" should be substituted for the word "allied" in this section of the law. This would authorize a selective call for other specialists, such as engineers, physicists, other scientists, et cetera, which might be needed by the military forces. Presently, the law provides only for the selective callup of medical, dental, or "allied" specialists.

The Association believes that physicians should be registered and classified in the same manner as other citizens in the same age group, deferred for educational purposes in the same manner as other registrants and called to active duty or inducted under the same general provisions as other registrants deferred for educational purposes.

It is noted that the pending bill proposes a four year rather than a two year extension of the Universal Military Training and Service Act. We believe the additional two year extension of time should be fully explained and justified to the Committee. We believe that this justification is necessary because scientific and technological advances have resulted in rapidly changing concepts of military manpower requirements. Consequently, there have resulted, directly or indirectly, current and projected reductions in the strength of the Armed Forces. It is conceivable that future manpower requirements may be subject to further downward revisions. A two year extension of the law would permit a timely review of military manpower requirements in light of pertinent changes in the then current military situations. The Association believes that this would be particularly desirable with respect to the callup of medical and allied specialists because of the increasing demands and requirements of the civilian population for the nation's medical and health resources.

As you know from our previous appearances before your Committee, the Association has had a keen and sustained interest in military medicine for many years. Through the Surgeons General of the military services, we have maintained a friendly and close working arrangement in the consideration and advancement of military medical affairs. We feel that the health of the nation requires a careful correlation of military and civilian medicine. In furtherance of this objective, the Association, working with the military services, has attempted to insure improvement in the utilization of medical manpower by the Armed Services and a strengthening of the career incentive program for medical officers.

On behalf of the American Medical Association, I would like to thank you for this opportunity to present our views on H. R. 2260 and to assure your Committee of our willingness to continue our assistance in providing the members of the military services with the finest medical care.

Yours sincerely,
F. J. L. Blasingame, M.D.
Executive Vice-President

STATEMENT OF THE AMERICAN MEDICAL ASSOCIATION ON S. J. RES. 41, 86th CONGRESS

THE INTERNATIONAL HEALTH AND MEDICAL RESEARCH ACT OF 1959
SENATE COMMITTEE ON LABOR AND PUBLIC WELFARE
BY GUNNAR GUNDERSEN, M.D.
FEB. 25, 1959

Mr. Chairman and Members of the Committee:

I am Dr. Gunnar Gundersen, a practicing physician from LaCrosse, Wisconsin. I currently am serving as the President of the American Medical Association, on whose behalf this statement is presented.

In addition to my position with the A. M. A., I am a member of the Council of the World Medical Association, an organization of 53 national medical associations comprising a membership of more than a half million physicians.

With your permission, Mr. Chairman, I should like to discuss briefly the interest and activities of the American Medical Association in connection with international health, medical care and medical education, and the philosophy and position of the A. M. A. with respect to the subject resolution which would establish a National Advisory Council for International Medical Research.

For many years the American Medical Association has played an active and far-reaching role in the international health field, because of its belief that physicians on every continent are dedicated to the assistance of all people regardless of race, color, creed, or social class in attaining the highest possible level of health.

Here briefly are a few of the ways in which the A. M. A. has acted specifically upon this belief:

1. The Association helped to organize and support the World Medical Association in 1948. We also approved and encouraged a United States Committee to aid the World Medical Association financially. This committee has provided, and is furnishing, funds to help finance the W. M. A. Secretariat, the publication of the *World Medical Journal,* and specific scientific investigations.

2. An A. M. A. representative has served with the U. S. delegation to the Assembly of the World Health Organization, a subsidiary of the United Nations representing governments in the field of medicine.

3. THE JOURNAL of the American Medical Association is promoted in foreign countries, and now serves as an "up-to-the-minute" medical textbook for approximately 10,000 subscribers overseas. It can be found in every recognized medical library in the world.

4. Likewise, our nine specialty journals reach thousands of physicians outside the United States, providing them with the latest medical information on subjects relating to their specialties.

5. The A. M. A. has established, developed, and maintained the valuable "Standard Nomenclature of Disease and Operations," the only international publication of its type.

6. The A. M. A. library staff compiles the "Quarterly Cumulative Index Medicus," a publication providing pertinent information on medical periodicals, literature, and books. Currently there are more than 1,300 foreign subscribers.

7. Other A. M. A. publications which have wide appeal among physicians abroad include "New and Non-Official Remedies" and "Useful Drugs." These publications provide physicians with information on the actions, uses, limitations, and dosages of new drugs.

8. A. M. A. medical films are loaned to medical societies all over the world. In the past 10 years the A. M. A. has received approximately 775 unsolicited requests from 70 countries for medical films. While it was impossible to fill all the requests, hundreds of films have been provided on a loan basis.

In addition, the A. M. A. has cooperated with many national medical societies in arranging film programs. This year a special film program has been prepared for the Japan Medical Society.

9. The A. M. A. has been vitally interested in the training, in American hospitals, of physicians educated abroad and is a participating member of an evaluation service for foreign medical graduates. In 1957-1958 a total of 7,622 physicians from 90 countries were trained in American hospitals as interns or residents. (Open Doors, 1958, prepared by Institute of International Education.)

10. This year the American Medical Association, along with the Association of American Medical Colleges, will play host to the Second World Conference on Medical Education in Chicago (Aug. 30-Sept. 4). Our Association again is giving its wholehearted cooperation to this conference which is expected to draw more than 1,500 persons from all parts of the world.

I am sure all of you are familiar with the dramatic television production, "MD International," sponsored by Smith, Kline & French Laboratories and the American Medical Association. The film was inspired by President Eisenhower's People to People speech, in which he said that one of the best roads to international understanding was through constructive personal contact among individuals of all nations.

"MD International" was premiered at the 1957 Clinical Session of the American Medical Association in Philadelphia. In introducing it, Dr. David B. Allman, who was then President of the Association, said:

"MD International is a warm and inspiring account of the activities of American doctors who chose to practice in the far corners of the world.

These physicians, and many like them, act as our unofficial medical diplomats. Not only do they carry modern medicine to people in remote areas but they also—through their daily lives and through dedication to their patients—help spread good will and understanding.

"The contribution of these doctors of medicine is a great steppingstone on the path to peace."

I have mentioned some of the ways in which the American Medical Association is working, with others around the world, to promote better health, medical care, medical facilities, and medical education.

Our Association feels that medicine has no geographical boundaries, for it truly is an international science for the benefit of everyone. Furthermore, we believe that only through coordinated effort can physicians throughout the world bring to their people the maximal health benefits that modern medicine can provide.

Today more than ever before medical men all over the world are interdependent. Consequently, physicians in America are interested not only in exporting new developments in the art and science of medicine but also we are equally anxious to import new techniques and discoveries by our colleagues in other countries. World-wide progress in medicine can continue in the future only through the free exchange of ideas between medical scientists in all countries.

Last June at the presidential inaugural ceremony of the American Medical Association I titled my address "Physicians to the World." Allow me to quote a few of the concluding lines from that address:

"In medical science there are no secrets, no iron curtains, no cold war. To physicians everywhere, atomic energy means a new way of fighting disease, not a new way of conquering the world. Medicine exists to save life, not destroy it."

Since medicine speaks a common language around the world we can combat physical and mental suffering with more medical knowledge and research. Obviously, there are enormous potentials for health and good living which are still unrealized both in the United States and in all other countries. In addition, there is a growing recognition that medicine, with its resources and influence fully mobilized, can perhaps do more for world peace than the billions of dollars being poured into armaments. There is a mounting conviction that the time has come when medical statesmanship must be used to augment the methods of political diplomacy.

I believe that Senate Joint Resolution 41, 86th Congress, will provide an important way in which the United States can contribute to the health and well-being of our own citizenry and of all the peoples of the world.

We in medicine have long recognized that native intuition and the ability to apply scientific methods of research are gifts which are not confined to people in only a few nations of the world. Men and women of science in all countries can contribute substantially to the expanding horizons of medical knowledge.

The establishment of the National Advisory Council for International Medical Research and the National Institute for International Medical Research can provide a vital vehicle for implementing and assembling our existing and potential forces of medical science.

After careful study of Senate Joint Resolution 41, I have a few other points that this committee may want to consider:

1. I believe that the World Medical Association is another of the already existing, tested means for international cooperation in matters relating to health. Therefore, it should be included along with the World Health Organization, the Pan American Sanitary Bureau, and the United Nations International Children's Fund, as international groups to cooperate with.

2. I agree basically with the manner in which the Council is to be appointed—"by the Secretary without regard to civil service laws." However, it would be my suggestion that the Secretary of the Department of Health, Education, and Welfare rely heavily on the surgeon general of the Public Health Service in making the appointments because of the professional character of the Council.

3. Naturally due care must be taken in supporting researchers in foreign countries because of the possible salary differential. While the financial grants to foreign researchers must be adequate—perhaps even attractive—the secretary and his advisers must see that the program does not adversely affect medical care and scientific research in foreign countries.

4. Generally, the Senate Joint Resolution deals with research, investigations, and experiments by individuals, universities, hospitals, laboratories, or other public agencies or institutions. However, there is a reference to grants for the improvement or alteration of facilities needed for medical research and research training. I believe that the

program should be one of research and not a research construction program. Perhaps it would aid and guide the secretary, the surgeon general, and the council if some general qualifications or limitations on grants for the improvement or alteration of facilities were added.

5. Finally, I believe that the greatest care should be exercised in setting up the research grants and research programs. Because of the vast amount of research being conducted today, all proposed projects must be scrutinized carefully.

Last December in my report to the House of Delegates of the American Medical Association, I stated that medicine should offer leadership and imagination on the international scene. At that time proposals for an International Medical Year were being made. In support of such a project I said that the American Medical Association should offer maximum help and leadership as a contribution to world understanding.

In furtherance of this belief, the American Medical Association offers its full support and assistance in the establishment of the National Advisory Council for International Medical Research and the National Institute for International Medical Research, proposed by S. J. Res. 41. We believe that the promotion of international health through research is one of our best means of promoting international cooperation and understanding. Whatever we do to promote good health also will promote peace in the world.

Thank you, Mr. Chairman and members of the committee, for giving me this opportunity to testify here today.

COUNCIL ON MEDICAL SERVICE

CHRONIC ILLNESS INFORMATION CENTERS

In most cities a wide variety of services and facilities are available for long-term patient care. These may range from a chronic disease hospital or an organized home-care program to nursing homes or visiting nurse and homemaker services. Whatever their function or sponsorship, they are too frequently either unknown to or overlooked by physicians having patients with illnesses that do not require general hospital care.

A comparatively recent approach to the better utilization of such services and facilities has been the establishment of what are being variously termed "central services for the chronically ill," "chronic illness information centers," or the like. These agencies provide information and referral services to physicians or to patients seeking the proper facility, conduct fact-finding studies on needs and resources for care, stimulate and coordinate planning, and, in general, serve as community clearing-houses on chronic illness planning and activity. The first such service was established in Chicago in 1944. Four others have been organized along similar lines at later dates in San Francisco, Milwaukee, Cleveland, and Essex County, N. J.

Although these agencies differ in the emphasis placed on various facets of their operation, all are organized to a greater or lesser degree around the following general functions: (1) to collect and maintain current information on all available community facilities and agencies offering service to the chronically ill or aged and to provide referral services to individual patients or other persons seeking the appropriate service; (2) to provide consultation and guidance to the operators of nursing homes, homes for the aged, and other long-term facilities in regard to standards of care, operating methods, and costs; (3) to conduct or participate in fact-finding research into the prevalence of long-term illness or disability in the community, the important unmet needs for care, and the additional facilities and services necessary; and (4) to initiate, stimulate, and coordinate community planning to meet these needs, through contacts and conferences with appropriate groups and individuals and through public education, both professional and lay.

The Council on Medical Service has undertaken an expanded program of research, education, and implementation in the various problem areas of aging and long-term illness. Because of the important role such information and referral centers play in coordinating care for these two groups, it was decided to gather information on their organization and operation, the types and needs of persons they serve, the special programs and projects undertaken, and the major problems encountered in serving the aged and chronically ill.

Reports on the chronic illness centers in Chicago and Milwaukee follow. Reports on the other three centers will appear in subsequent issues of THE JOURNAL. It is believed that the data obtained will be of interest to physicians, medical societies, and other groups and individuals who are either involved in the care of these types of patients or concerned with the over-all problems of aging and long-term illness.

CENTRAL SERVICE FOR THE CHRONICALLY ILL OF THE INSTITUTE OF MEDICINE OF CHICAGO

The Central Service for the Chronically Ill of the Institute of Medicine of Chicago began operation in January, 1944, with the financial sponsorship of the Community Fund. Its inception had been preceded by more than 10 years of increasing concern and tentative planning for the growing number of chronically ill in Chicago, on the part of various committees of the Welfare Council, the Institute of Medicine, and other medical, public health and welfare agencies. In the fall of 1942, plans were crystallized when the Welfare Council Committee on Chronic and Convalescent Care recommended that a special agency be established to devote full-time attention to the needs of the chronically ill and the community services necessary to meet these needs. It was intended that the agency would serve as a central point for assembling comprehensive and current data on facilities for the chronically ill in Chicago and on the improvements and additional facilities needed, would concentrate the interest of medical and welfare groups and the general public on these unmet needs, and would formulate specific proposals for improvement of care. It would also provide information on the best services available to patients or other persons seeking care.

In the belief that the work should be under medical auspices, the welfare council had approached the Institute of Medicine during the planning stages with a suggestion that the institute sponsor the project and had added representatives of the institute to the planning committee. Funds for the work became available before final arrangements for sponsorship had been completed, and, to avoid delay, the project was established under the auspices of the welfare council, with institute representation on the governing committee. It operated in this way for the first four months of its existence. On May 1, 1944, it was formally transferred to sponsorship of the Institute of Medicine with the same governing committee, including representatives of the welfare council, and with the same staff and program. A representative of the welfare council continues to serve on the governing board of the Central Service for the Chronically Ill, and, in this and other ways, efforts are made to coordinate the work of the two organizations.

Early in the work of the central service the purposes and program were broadened to include activities directed toward prevention and control of long term illness, as well as toward the improvement of care. These revised purposes, which have directed the central service's activity to the present, are (1) the determining of the important problems of chronic illness in the community through fact-finding studies and accumulation of information from other sources on the number of chronically ill persons, the nature of their disabilities, the services required to meet their needs, the kinds of agencies and institutions best able to provide the necessary services, the part each should play in the total community program, and the ways in which the various personnel, agencies, and institutions should be integrated with each other in providing service; (2) the development of a comprehensive plan outlining the additional services and facilities required in the community and promotion of the development of these facilities through education, consultation with persons and organizations planning new facilities, and other methods; (3) the promotion of the most efficient use of existing services by providing information, counseling, and referral to patients and their families, physicians, health and social agencies, and others seeking suitable facilities for care; (4) the furthering of the effective programs for the prevention and control of long-term illness by encouraging additional effort in this field and by coordinating the facilities and services for care with those whose primary activities are related to prevention; and (5) the fostering of good standards of care and rehabilitation for the chronically ill and disabled at home and in all types of institutions by developing and making available to the personnel and institutions involved specific descriptive and standard-setting material on the quantity, quality, and reasonable costs of services and supplies necessary for adequate care, and by providing consultation in problems of management and administration to these institutions and facilities.

Although the information and counseling service has been operated continuously since the central service was established, a major part of the organization's work up until 1954 revolved around the collection of community-wide data on the needs of the chronically ill, the formulation of standards, and the development and promotion of a community plan to meet the needs. By 1954, the major community problems of chronic illness had been identified and clarified. Information had been collected on the types and extent of additional services and facilities needed, the advantages and disadvantages of various methods of organizing these services, costs, and possibilities for financing; the comprehensive community plan had been developed. This brought to a close the temporary purposes for which the center had been established.

The need continued, however, for referral and counseling services to individual patients and for guidance and consultation to facilities caring for these patients, particularly private nursing homes. In response to considerable community pressure, and with financial help from the Chicago Medical Society, Community Fund, Chicago Community Trust, Illinois Division of the American Cancer Society, Chicago Heart Association, and some private foundations, the central service was established on a permanent basis in the Institute of Medicine to continue these two functions. It has been operating on this basis up to the present.

Organization and Operation

The central service now occupies an office in the John Crerar Library Building adjacent to the general offices of the Institute of Medicine in downtown Chicago. Organized as a separate corporation, it operates under the jurisdiction of the Institute of Medicine's Committee on Chronic Illness, which acts as the board of directors. This committee includes eight physicians, an administrative nurse, an executive of the welfare council, two lawyers, and four other lay persons.

The agency began operation with a staff of five: a director, a consultant on standards who was a home economist familiar with the development of quality-quantity-cost standards, a nurse and a medical social worker designated as consultants on resources, and an office secretary. With the termination of the special fact-finding phase of the agency's work, the position of consultant on standards was discontinued. An additional typist has since been added, leaving a present active staff of five.

The director of the central service is a registered nurse, with a bachelor's degree. Her duties, in addition to administrative supervision of staff, include reporting to the board on all agency operations and activities and implementing all decisions of this group, formulating new policies and programs, employment of personnel, expenditures of funds, and representing the service to the community.

The two consultants on resources are responsible for the collection and maintenance of information on the available nursing homes, institutions, agencies, and other facilities in the community and for day-to-day counseling with patients and other persons seeking suitable facilities for care. Information is collected and kept up to date through visits, telephone calls, summarizing of reports from agencies, institutions, and patients, and other methods. Much of the work toward improving quality of care is carried on during visits to the homes and institutions, through the provision of consultant service to operators of the facilities, and through the distribution of printed material.

The secretary and a typist handle the major part of clerical-administrative detail inherent in the agency's operation. Their duties include maintaining administrative files of the agency, preparing financial and statistical reports and records, handling staff schedules and payrolls, purchasing of supplies as authorized by the director, and performing stenographic work for the professional staff.

Request for service forms are kept for each patient or other person contacting the central service, giving diagnosis, degree of disability, services requested and needed, action taken, and other pertinent information. The service also maintains detailed individual records on agencies, homes and institutions, sources of financial assistance, and all other resources for long-term care or service in the community, and it has abbreviated this information in a desk card file for quick reference. Finally, the service maintains over-all statistical information on the relationship of needs and resources for care in Chicago. This includes full information about resources for care of patients in their homes and a yearly register of all nursing and old-age homes, hospitals, rehabilitation centers, and other institutional facilities serving long-term patients, giving bed capacity and type of ownership or auspices.

Services to Patients

In line with the central service's policy to act purely as an information and counseling center, rather than as a case-work agency, persons requesting service are accepted without any prior investigative procedures. For this same reason, and because of the expense involved, the service does not attempt any organized follow-up of patients to see whether a satisfactory solution or placement has been completed.

The service has not attempted any community-wide publicity campaign directed toward patients or other agencies. The annual reports of the central service are reprinted in the Proceedings of the Institute of Medicine, and there has been an occasional article or editorial in this publication. Notices of the availability of the service are published from time to time in the Bulletin of the Chicago Medical Society, and descriptive listings are carried in the Welfare Council's Social Service Directory and the classified telephone directory.

There have been a number of informational mailings about the service to physicians in Chicago and Cook County, and a letter and leaflet recently were sent to all physicians in the area, all clergymen, and a selected list of lawyers, trust officiers, and personnel directors in various business and industrial establishments. Finally, there have been sporadic newspaper articles and radio announcements concerning the availability of the service. Current thinking is that more publicity specifically directed toward the service's informational and counseling functions would be helpful.

During the calendar year 1958, a total of 2,892 patients or other persons sought information or counseling at the service center. Of these requests for service, 433 were recall cases, or patients who had previously contacted the center and 314 were requests for service not related to an individual patient. Table 1 shows the number of requests during 1956, 1957, and 1958, divided by new and recall cases, and other requests not concerned with a specific patient.

A special tally of a randomly selected 100 patients served during December, 1957, shows that 83% of these were over 60 years of age. Three-fifths, or 60% of this group, were women, a proportion which has held relatively constant over the years of operation. Of the cases on which the data were available, 27% of the patients were married and 73% were single, widowed, separated, or divorced; 26% were in hospitals at the time of contact, and an additional 14% were in nursing homes, boarding homes, and other institutions; 14% were living at home with husband or wife, 27% with other relatives or friends, and 19% alone. The proportions of ambulant, semiambulant and bedridden patients referred to the service have been relatively constant since its inception, as have been the number of patients able and unable to pay full costs of care.

TABLE 1.—*Persons Served in 1956, 1957, and 1958*

* Patients known to center for first time.

† Patients who have received previous service from center.

‡ Requests for service not related to specific patient.

Table 2 gives a breakdown of these 100 newly referred cases by age, degree of disability, financial status, source of referral to the service, and other characteristics.

Needs of Patients

During September and October, 1958, nearly 65% of patients contacting the central service for the first time requested nursing home or other institutional care. The next most frequent requests were for some type of housekeeper-attendant service and for general counseling and help in planning a patient's care. Other requests were for information on some specific facility, home nursing care, or rehabilitation services. Table 3 shows the nature of requests for service among 638 calls received by the central service during September and October, divided by new and recall cases. Also included are calls received from nursing home operators on management problems, from persons planning to establish such facilities, and from individuals and organizations seeking general information on needs and resources.

Some 60 to 65% of all patients requesting service are given help in finding homes and institutions providing long-term care. Another 10 to 12% of patients are given information or counseling on home-care services or resources for financial assistance. Five to eight per cent of patients are referred to social case work agencies. Other referrals are to rehabilitation facilities and similar community services. For a small number, further medical or psychiatric evaluation is recommended before attempting a plan for care.

Problems and Developments

The important unmet needs and problems of Chicago's chronically ill, as evidenced by requests to the central service and by its extensive fact-finding work in the community, seem to revolve around a need for substantial improvements in financing of services; a shortage of good inpatient facilities for long-term care; a need for broadening the range of services offered, especially rehabilitation services within the various long-term institutions; some deficiency in the services available to help patients and their families at home; and a need for closer coordination of the activities of the many different organizations now becoming involved in the planning and development of community services in the field of chronic illness.

At present, in Chicago, there are about 16,000 beds for long-term care—in special hospitals for treatment and rehabilitation of the chronically ill; in voluntary, public, and private nursing-care facilities; and in infirmary sections of homes for the aged. Although this represents an encouraging growth from the some 10,000 beds available at the time of the central service's inception, and is not far short of the total number needed, at least 6,000 of these presently available beds are of such poor quality and offer so little possibility of substantial improvement that they should be replaced by new facilities. Most of these 6,000 substandard beds are

* Figures are weighted toward self-supporting persons, as arrangements for care of financially dependent usually are made by welfare agencies.

in small proprietary nursing homes in the city, and the central service feels that this is a reflection of two primary factors. One of these is the fact that many of the operators of these facilities have not had the experience or training necessary to provide good care economically and efficiently. Until recently there have been no institutes, training centers, or other educational resources from which these operators could obtain guidance in organizing and operating a nursing home, or even any books or journals devoted to this subject. There has been a definite need, first, for a specific definition of what good care consists of, and what is required to provide it in terms of organization and ownership of nursing home facilities, relationships between these facilities and other inpatient care institutions, physical plant and equipment, numbers and training of personnel required, and costs; and, second, for educational channels through which this information can be made available to the owners and operators of the facilities.

A major part of the central service's work has been directed toward these needs. A 400-page book giving practical guidance for persons planning to establish new homes and institutions has been published by the service, and a companion volume on organization, management, and budgeting procedures is forthcoming. Hospital organizations and journals are publishing material of this type with increasing frequency. A number of short training courses covering patient care, personnel, management, budget, and other such areas have been set up for nursing home owners and operators, and efforts along this line are increasing. The second important factor in the inadequacy of many proprietary nursing homes has been the lack of sufficient funds to provide good care, particularly for public assistance recipients.

The central service continues to urge and work for more realistic standards of payment for public assistance recipients, through its contact with other agencies and individuals in the community, talks and programs before interested organizations, and cooperating with the Health Division of the Welfare Council in efforts to improve the payment standards now in use by the Illinois Public Aid Commission.

Services to the Community

From its inception in 1944 up until 1955, a major part of the central service's work was taken up with various special studies into the nature, prevalence, and problems of chronic illness in the Chicago area. In addition to the broad, day-to-day collection of information on the number, types, and needs of chronically ill, and the community services required to meet these needs, the service has completed the following specialized studies: (1) terminal care for cancer patients—a study of the facilities available and needed in Chicago for care of this group, specially financed by the American Cancer Society; (2) a specially financed study of the services available and needed for home care; (3) the need for institutional facilities for the long-term care of children; (4) the need for special institutional facilities for young adults; (5) an analysis of personnel and services required in different types of homes and institutions for long-term care; and (6) costs of care in long-term institutional facilities, compared with the costs of home services for the chronically ill.

By the end of 1954, the central service had identified and clarified the major problems and unmet needs of the chronically ill in Chicago and had assembled information on the services needed and extent of the need, types and numbers of agencies and institutions required, the pros and cons of various forms of organization of services, probable costs, and the possibilities for financing. The central service has developed and is planning to publish a model plan for a coordinated community-wide program in Chicago directed toward all aspects of the chronic illness problem—early diagnosis and prevention; care and rehabilitation of the long-term patient at home, in hospitals, nursing and old-age homes, and other institutions; coordination of community facilities and services; fund-raising and financing of care; maintenance of statistical information on needs as related to facilities available; and the basic community and professional services needed in research, professional, and public education, and licensing and standard setting for institutions and personnel.

Table 3.—*Nature of Requests for Service Among 638 Calls Received During September and October, 1958*

Type of Request	Percentage of Total Cases		
	New Cases	Recalls	Total

Additional information only	...	23.3	2.7
Total	100	100	100

Other material published or about to be published by the central service includes a 25-page pamphlet summarizing methods for surveying community needs and resources for long-term care; a 55-page booklet on the role of the nurse in caring for the chronically ill; a monograph on community services for rehabilitation; a monograph on licensing and standard-setting for long-term care institutions; a casework manual for welfare agencies to assist them in arranging care for the chronically ill patient; and a monograph on home-care services.

Finally, the professional staff of the service continues on a day-to-day basis to counsel with the operators of institutions providing long-term care, particularly privately owned nursing homes, in efforts to develop and maintain good standards of care, and to maintain and make available to the community centralized information about the needs and resources for care of the chronically ill in the Chicago area.

CENTRAL AGENCY FOR THE CHRONICALLY ILL OF MILWAUKEE

The Central Agency for Chronically Ill, of Milwaukee, was established in February, 1948, as the result of a two-year study into the problems and unmet needs of chronically ill persons in Milwaukee County. This study, which was financed by the Women's Club of Wisconsin and conducted by a special study committee of physicians and other citizens appointed by the Community Welfare Council of Milwaukee County, showed a need for some type of central clearing house to collect information on the facilities providing long-term care and the additional facilities and services needed in the county. The study committee was then charged with developing, in cooperation with other agencies, a central information-gathering and educational service for the chronically ill.

The central agency was supported through its first years by a grant of $10,000 from a service club and presently by the Community Chest, of which it is a participating agency. Its objectives are (1) to gather and maintain current information on nursing homes, homes for the aged, and other facilities providing service for the long-term patient and to assist with placements in these facilities; (2) to stimulate through community education the setting aside of additional hospital beds for long-term illness, the expansion of good nursing home facilities, the extension of bedside nursing care in private homes, and the development of additional facilities for recreation and rehabilitation; and (3) to stimulate further study of degenerative diseases from all aspects.

Organization and Operation

The central agency occupies a small office in the downtown Milwaukee area. The original staff consisted of the executive director and an office secretary. A professional staff worker was added as operations progressed. The central agency functions under the supervision of a 21-man board of directors, representing the fields of medicine, industry, finance, law, the clergy, public relations, and service groups. This board, which meets once monthly, is responsible for over-all policies of the agency and for approving budget expenditures and any changes or additions in the agency's program. The agency is organized as a corporation, with an unlimited number of members who are elected for five-year terms. These members represent various fields and professions in the community, participate in special program meetings several times a year, and serve as a reservoir from which to draw new members for the board of directors.

The executive director of the agency is a registered nurse, with a masters degree in public health. Her duties, in addition to over-all administrative supervision of the agency and preparation of the budget, include formulating new programs and policies for the agency and submitting them to the board of directors and the Community Welfare Council, interpretation of agency policies and programs to the community, developing educational programs and institutes directed toward the general public and various professional groups, securing data and preparing reports on the individual and community problems of long-term illness, and continuous liaison with other community social and health agencies in order to foster a coordinated approach to problems of the chronically ill.

The professional staff worker is a registered nurse with a degree in public health nursing. Under supervision of the executive director, she is responsible for counseling and referral of patients seeking nursing homes and other facilities for care, for visiting and evaluating all nursing, old-age, and foster homes within a 50-mile radius of Milwaukee, for keeping a running file on these facilities, and for consulting with persons planning new nursing homes and other such facilities in regard to standards of care. Her duties also include meeting regularly with state and local organizations of nursing home operators and assisting these operators with problems related to management efficiency, nursing care, and costs.

The office secretary handles most clerical-administrative detail in the agency's operation, including typing, maintaining files and records, and serving as receptionist and telephone operator. Monthly narrative, statistical, and financial reports on the agency's operation, in addition to an annual report, are prepared jointly by the director and the staff worker and distributed to the board and all corporation members. Other records and files maintained in the office include request-for-service forms for all patients or other persons seeking information—these include diagnoses and the name of the physician in charge for all patients—a complete nursing home evaluation report on all facilities visited by the staff worker and a summary of these evaluation reports in a desk card file. The agency also maintains a reference library of books and other educational material.

Services to Patients

About one-fourth of the time of the professional staff is taken up with counseling and referral of patients to nursing homes or other institutions and services for the chronically ill. The central agency has not attempted any intensive publicity toward this facet of its operation. Articles noting the availability of the counseling service have been published from time to time in the local newspapers, and the agency has published brochures or pamphlets directed toward persons seeking information on the services available in Milwaukee. Patients seeking information or placement counseling are accepted for service without any prior investigative or casework procedures. The agency has at times had sample clearances with the Social Service Exchange in Milwaukee but decided against making it a routine practice. The agency does not attempt any organized follow-up of patients to see whether the referral or placement made in individual cases has been completely satisfactory.

* *Includes more than one type of contact by some patients.*

The number of patients and other persons seeking help at the agency has increased slowly but steadily since its inception in 1948. In the fiscal year 1954-1955, 619 new patients or other persons contacted the agency for service; in 1955-1956, 688, and in 1956-1957, 693 new patients were served by the agency. At present patients are referred to the agency by their families, themselves, the Visiting Nurse Association, hospitals in Milwaukee, physicians, lawyers and courts, and friends, in about that order of frequency.

Of the 513 individual patients referred to the agency during the calendar year 1957, over 85% were 60 years of age or older. This age percentage has held relatively constant over the years of operation, with an average patient age near 75. Over three-fifths of patients referred to the center were women, a proportion which has also held constant. About 77% of the patients were widowed or single, 25% lived alone, and 22% lived with relatives. An increasing percentage of bedfast or incapacitated patients have sought help at the agency in recent years. The percentage of senile or mentally disoriented patients referred to the agency has also risen. Table 1 shows the characteristics of individual patients referred to the agency during the calendar year 1957 by age, degree of disability, living arrangements, financial status, and other factors.

Needs of Patients

In the period from October, 1957, through September, 1958, requests for 24-hour nursing, boarding, or other institutional care accounted for a little over 36% of all needs for service among newly referred patients or other persons. The next most frequent requests were for counseling or educational material. Other frequent requests among new contacts were for information on establishing a new facility for care and for information on sheltered or home employment and custodial day care. Table 2 shows the nature of requests for service received during this period, divided according to new and recall patients. Not included in this tabulation are some 259 calls received from nursing home operators during this period, reporting vacancies or the filling of vacancies in their facilities.

The community facilities or services to which patients are most frequently referred have been nursing and old-age homes, the Welfare Department, Visiting Nurse Association, the Family Service Agency, and the local Old-Age and Survivors Insurance (OASI) Bureau.

Problems and Developments

As a result of its referral and fact-finding work with patients and other individuals and agencies in the community, the central agency has been able to pinpoint some of the more pressing problems in meeting the needs of Milwaukee County's chronically ill. There is an urgent need at present for some type of visiting homemaker or housekeeper service which could be made available to the considerable number of chronically ill or infirm patients living at home. Such a service has been approved by the Visiting Nurse Association, but its inception has been delayed by a difficulty in recruiting housekeepers. The central agency is also planning to inaugurate, on a demonstration basis, an organized home-care program similar to those operating in other communities. This project is presently awaiting the approval of the Milwaukee Medical Society.

Another major problem is the lack of suitable facilities for care of the "in-between" type of senile patient, who is too much of a supervisory problem for the average nursing home operator but does not need or belong in a mental institution. Progress on this problem has been nil to date. There is also a lack of suitable nursing care facilities for persons in the middle and higher income group who desire and are able to pay for a private room and bath. The central agency, in its consultation work with nursing home operators, has stimulated those persons planning new or improved facilities to include more such private and semiprivate accommodations in their planning.

Finally, the agency feels that there is a definite need for additional organized inpatient rehabilitation services. Milwaukee has adequate rehabilitation services at the outpatient level, but more inpatient facilities than those presently provided by the general hospitals of the city are needed.

Services to the Community

More than 40% of the working time of the director and staff worker is taken up with activities of a community-wide nature—classes, talks and other educational projects, visits to nursing homes and counseling with their operators, and assistance to nursing home organizations, both state and regional. The central agency has sponsored, organized or participated in a number of annual workshops for nursing home operators. These workshops have utilized the educational resources of a number of state and local agencies and organizations and have covered such areas as nursing service, nutrition, rehabilitation, administration, budgetary and management problems, enlistment and training of nursing home personnel, and broad trends in the nursing home field. The first such workshop was given by the agency in Milwaukee in 1951, with the help of the newly formed Milwaukee County Nursing Home Association. Two similar programs were given in the years following, and in 1954 a statewide workshop was held in Milwaukee in cooperation with the Marquette College of Nursing and the State Nursing Home Association. Another statewide program was held in 1955, conducted jointly by the central agency, the University of Wisconsin Extension Department, the State Health Department, and the State Nursing Home Association; similar workshops have been given up to the present.

The central agency has compiled and published a small fact booklet on the patients in Milwaukee's proprietary nursing homes. The booklet gives statistical information on age, sex, diagnoses, types of care required, referral sources, patient income, and costs of care. These data were obtained with a special questionnaire used by the staff worker in the course of her routine nursing home visits.

Other informational and educational material published and distributed by the agency includes a brochure on the important problems of chronic illness written for the general public, a 12-page booklet giving some of the general points to be considered by patients and their families in selecting a nursing home, and a similar booklet highlighting some of the essential problems in the operation of a nursing home, directed toward administrators of these facilities.

A recent project has been the mailing of a quarterly "Food Notes" bulletin to nursing home operators and cooks. This 2-to-4-page bulletin, which is prepared with the help of the Milwaukee Health Department nutritionist, notes some of the plentiful and easily obtained foods in a particular season, gives suggestions for their use in menus, and contains recipes in serving quantities for from 10 to 50 persons. Suggestions are also given on attractive and efficient serving methods, special dishes, and the like.

TABLE 2.—*Nature of Requests from Oct. 1, 1957, to Sept. 30, 1958*

Total	1,428	154	1,582

* Persons previously receiving service from agency

The director of the central agency is co-author of a book on the care and rehabilitation of the chronically ill; she continues to write articles and develop exhibits, literature for distribution, and other educational material on the general and specific problems of the chronically ill and their care.

The central agency is currently investigating the possibilities for future study and action in such areas as encouraging the development of new skilled nursing care facilities by church and other nonprofit groups, who have not been too active in this field in the past, possible contributions by the general hospital in improving long-term care, improved methods of caring for the homebound chronically ill, and a study of the incidence of chronic disease in certain special groups, such as the Negro population and industry. The agency continues to work toward fostering an enlightened public attitude toward the problems of the aged and chronically ill and to stimulate the coordination of community facilities and services in meeting these problems.

MEDICAL NEWS

ARIZONA

Annual Meeting in Chandler.—Preliminary plans for the 68th annual meeting of the Arizona Medical Association in Chandler, April 30-May 2, were announced by Dr. Dermont W. Melick, of Phoenix, chairman of the scientific assembly committee. Papers will be presented by Drs. Haddon M. Carryer, Mayo Clinic; John W. Cline, Stanford University; Harold D. Jenkins and Marvin E. Johnson, University of Colorado; Henry H. Kessler, Kessler Institute for Rehabilitation; Johannes M. Nielsen, University of California at Los Angeles School of Medicine; and Thomas L. Royce, Baylor University. As a special feature, a medical education workshop will be held May 1. Presentations on medical education will be given by Dr. John Z. Bowers, University of Wisconsin; Fred Dow Fagg Jr., Ph.D., president, Western Interstate Commission for Higher Education; Mr. Reuben Gustavson, president, Resources for the Future; Walter L. Hard, Ph.D., University of South Dakota; and Drs. Marvin E. Johnson, University of Colorado; Vernon W. Lippard, Yale University; Roscoe L. Pullen, University of Missouri; Thomas L. Royce, Baylor University; and Thomas B. Turner, Johns Hopkins University. Moderator will be Dr. John W. Cline, Stanford University. The meeting will be held in the San Marcos Hotel. Officers of the association are Dr. Wilkins R. Manning, Tucson, president; Dr. Dermont W. Melick, Phoenix, president-elect; Dr. Lindsay E. Beaton, Tucson, vice-president; Dr. Leslie B. Smith, Phoenix, secretary; and Dr. Clarence E. Yount Jr., Prescott, treasurer.

ARKANSAS

Annual Session Planned at Fort Smith.—The 83rd annual session of the Arkansas Medical Society will be held April 12-15 at the Goldman Hotel, Fort Smith. The president's address will be given the morning of April 13 by Dr. Louis K. Hundley, Pine Bluff. "Third Party Payment for Medical Care" will be presented by Dr. Frank C. Coleman, Des Moines, president, College of American Pathologists, that afternoon. Out-of-state speakers include the following:

Drs. Harold O. Perry, Rochester, Minn.; Lt. Col. George R. Steinkamp, M.C., U. S. A. F.., Randolph AFB, Texas; I. Frank Tullis, Memphis, Tenn.; J. E. Markee, Durham, N. C.; M. T. Jenkins, Dallas, Texas; Conrad G. Collins and Edgar Burns, New Orleans; Hugh F. Hare and Howard House, Los Angeles; Harris D. Riley, Oklahoma City, Okla.; William Dameshek and Kenneth W. Warren, Boston.

Specialty section meetings are planned for April 14, with the annual banquet to be held that evening. Dr. F. J. L. Blasingame, Executive Vice-President, American Medical Association, will address the House of Delegates the afternoon of April 12. Films and exhibits are arranged. Entertainment includes a golf tournament. For information write Mr. Paul C. Schaefer, Kelley Bldg., Fort Smith, Ark., Executive Secretary.

COLORADO

Plan Expansion of Tuberculosis Research Facilities.—The Colorado Foundation for Research in Tuberculosis, housed in the Webb building on the University of Colorado Medical Center campus, Denver, will add a third floor to the structure to expand its facilities for research in biochemistry and the genetics of bacteria. Dr. Roger S. Mitchell, director of the foundation, said the organization has the necessary funds to move forward with construction as soon as the Board of Regents approves the details. He added that Dr. Oscar Reiss, of the Johns Hopkins University School of Medicine, Baltimore, will join the staff in June to head this new activity. The Colorado Foundation for Research was established in Colorado Springs in 1922 by the late Dr. Gerald E. Webb, and was moved to the Medical Center campus in 1954. Dr. James J. Waring, professor of medicine emeritus, at the School of Medicine, is the foundation president.

DISTRICT OF COLUMBIA

Dedicate Hospital Research Center.—On March 22 Children's Hospital of the District of Columbia dedicated its new Children's Hospital Variety Club Research Center. Dedication speaker was Dr. Leroy E. Burney, Surgeon General, U. S. Public Health Service. The research center, located next to the hospital, at 12th and W Streets, N., was built at a cost of about $800,000, financed in part by grants totaling $484,000 and by a contribution of $200,000 from the Variety Club of Washington. Additional funds are being raised in a campaign for $460,000 launched last November. The Children's Hospital Variety Club Research Center, which commemorates the Variety Club's Chief Barker, Fred S. Kogod, is a modern building with three floors and a basement. The front is of heavy, opaque glass

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

and aluminum, and the sides are of brick to complement existing hospital buildings. In the air-conditioned building all necessary services (water, electricity, gas, compressed air) will be available in each research unit. Movable partitions will allow rearrangement of research areas without extensive repairs and remodeling. In addition to the laboratories of the seven research sections there is a radioisotope laboratory and a large sterilizing room with equipment for washing and sterilizing glassware. The Research Foundation of Children's Hospital was incorporated in 1947 to further pediatric research at Children's Hospital. Its president is Dr. Edgar W. Davis, and the director of the foundation is Dr. Robert H. Parrott, physician-in-chief of Children's Hospital.

HAWAII

Annual Convention in Hilo.—The Hawaii Medical Association will hold its 103rd annual meeting in Hilo April 23-26 at the American Legion Hall. Panel discussions on "Coping with the Teenager" and "Hernia Hydrocele and Undescended Testicle" will be moderated by Drs. J. Roswell Gallagher, Boston, and Tague C. Chisholm, Minneapolis, respectively. The following papers are scheduled:

Rehabilitation of the Hemiplegic, Dr. R. Frederick Shepard.
Cerebral Hematoma, Dr. John J. Lowrey.
Portal Hypertension, Experiences in the Management of Hemorrhage from Esophageal Varices, Dr. Gilbert C. Freeman.
Improving Medical Certifications of Death, Dr. Halbert L. Dunn.
Pitfalls in Surgery of the Hand, Dr. Leabert R. Fernandez.
Surgical Approach to Fascial Space Infection in the Hand, Dr. Raymond G. Chang.
Study of Lipoproteins in the Nisei, Dr. Kyuro Okazaki.
Report on Coronary Atherosclerosis in our Different Ethnic Groups from a Successive Series of 2,000 Autopsies, Dr. Nils P. Larsen and Dr. Walter M. Bortz.

The presidential address will be given by Dr. William N. Bergin. Exhibits are planned, and the annual golf tournament will be held April 26. Woman's auxiliary activities include a golf tournament April 25. Registration fee is $10.

ILLINOIS

Chicago

Visiting Pathologist.—Dr. R. Winston Evans, pathologist of Liverpool, England, has started teaching as temporary visiting professor of pathology at the University of Chicago. He is lecturer in the department of clinical pathology at the University of Liverpool and a consultant pathologist at the David Lewis Northern Hospital and the St. Paul's Hospital in Liverpool.

Dr. Jensen Receives Pasteur Award.—Lloyd B. Jensen, Ph.D., was chosen to receive this year's Pasteur Award, the Society of Illinois Bacteriologists announced. Formal presentation of the sterling silver medal and cash award will be made April 11 at a dinner meeting of the society in the Morrison Hotel. The Pasteur Award is given for "notable contributions to the science of bacteriology." The award is given to Dr. Jensen "for his outstanding contributions to food microbiology." For 27 years prior to retirement in April, 1958, he was chief bacteriologist at Swift and Company. He also lectured for 16 years at the U. S. Army Meat and Dairy Hygiene School on Pershing Road. In 1954 he was appointed consultant to the Walter Reed Army Institute of Research by the Surgeon General. Dr. Jensen was one of the founders and early editors of the journal, *Food Research.*

Appoint Dr. Kronfeld Department Head.—Appointment of Dr. Peter C. Kronfeld, of Wilmette, as professor and head of the department of ophthalmology, University of Illinois College of Medicine, was approved March 12 by the board of trustees. Dr. Kronfeld also was named ophthalmologist-in-chief of the University of Illinois Hospital and the Illinois Eye and Ear Infirmary. He has been professor of ophthalmology at the U. of I. College of Medicine and attending ophthalmologist at the infirmary since 1947. He joined the faculty of the university's professional colleges in 1943. Dr. Kronfeld succeeds Dr. William F. Hughes, also of Wilmette, who resigned the positions last September, but has continued on the College of Medicine staff as clinical professor of ophthalmology. Dr. Howard L. Wilder, assistant professor of ophthalmology, has been acting head of the department. Dr. Kronfeld received his M.D. from the University of Vienna and joined the staff of the University of Chicago in 1927 and remained there until 1933.

KANSAS

Annual Lecture Given.—The annual Clendening Lecture at the University of Kansas School of Medicine, Kansas City, was delivered by Dr. Edward H. Hashinger, professor emeritus of medicine and gerontology, on March 12. "Arthur E. Hertzler—the Kansas Horse and Buggy Doctor" was the subject of his tribute to the Kansas physician who was on the faculty of the school for over 30 years prior to his death in 1946. The Clendening series was established in 1949 by the widow of the late Dr. Logan Clendening, a pioneer in medical education at the Kansas School. Dr. Hashinger had residency training in the Halstead, Kansas, Hospital founded by Dr. Hertzler, who received international recognition for his best-seller, "The Horse and Buggy Doctor."

MASSACHUSETTS

Dr. Fulton Named First Warren Professor.—Prof. George P. Fulton, Ph.D., of Lexington, chairman, department of biology, Boston University's College of Liberal Arts, was named to the first Shields Warren Professorship at Boston University, according to an announcement by President Harold C. Case. The chair was established a year ago on the occasion of the 60th birthday of Dr. Shields Warren, of West Newton, pathologist and chairman of the executive committee of the Boston University board of trustees. At that time, some 700 Greater Bostonians donated funds to establish the professorship at Boston University, in honor of Dr. Warren, whose grandfather was the university's first president. Dr. Fulton was a pioneer in the use of the hamster cheek pouch method of studying the small blood vessels. Last year, Dr. Fulton was a visiting professor of physiology at the Stanford University School of Medicine in San Francisco for seven months. He is associate editor of *Angiology* and a fellow and vice-president of the American College of Angiology.

MICHIGAN

Annual Cancer Day in Flint.—The Genesee County Medical Society will present its 14th annual Cancer Day, April 22, at the Merliss Brown Auditorium, Hurley Hospital, Flint. Dr. Jackson E. Livesay, president of the society, will open the meeting with an address. Presiding officers at the forenoon and afternoon sessions will be Drs. G. B. Saltonstall, president, Michigan State Medical Society, Charlevoix, and James W. Logie, president, Kent County Medical Society, Grand Rapids. Topics and speakers are as follows:

The Current Status of Interstitial Irradiation, Dr. Ulrich Henschke, New York City.
Head and Neck Cancer as Seen in the Oral Cavity, Dr. Danely P. Slaughter, Chicago.
The Current Status of Cancer Research, Dr. Freddy Homburger, Cambridge, Mass.
The Problem of Soft Tissue Tumors as Seen by the Surgical Pathologist, Dr. Raffaele Lattes, New York City.
Extended Operations for Cancer of the Stomach and Colon and the Second Look, Dr. Owen H. Wangensteen, Minneapolis, Minn.
The Problem of Pigmented Mole and Malignant Melanoma, Dr. George T. Pack, New York City.

MISSISSIPPI

Annual Meeting of State Psychiatrists.—The newly formed Mississippi Psychiatric Society, a district branch of the American Psychiatric Association, held its first annual meeting on March 7 at the University of Mississippi Medical Center, Jackson. Dr. J. G. N. Cushing of Baltimore, southern area representative on the policy committee of the Assembly of District Branches, addressed the group on historical aspects of the American Psychiatric Association and the formation of district branches. Dr. Hamilton F. Ford, of the University of Texas Medical Branch, Galveston, gave the academic lecture on "Phrenotropic Drugs—Applicability Based on Chemical Grouping." Dr. Floy Jack Moore, chairman, department of psychiatry, University of Mississippi Medical Center, was elected president to succeed Dr. Frank A. Donaldson, of Jackson. Others elected as the first complete slate of officers were: president-elect, Dr. Lawrence G. Behan, Gulfport; secretary-treasurer, Dr. L. C. Hanes, Jackson; council member, Dr. John J. Head, Whitfield; delegate to assembly of district branches, Dr. William L. Jaquith, Whitfield; and alternate delegate, Dr. Beverley E. Smith, Jackson.

MISSOURI

Hospital Lecture.—The Jewish Hospital of Saint Louis announced that the 12th Jack H. Tritt Memorial Lecture was given April 2 by Dr. Edwin P. Hiatt, chief, Aero Medical Laboratory, Wright Air Development Center, Dayton, Ohio, on "Medical Problems of Manned Space Flight."

NEBRASKA

Student Aid Fund Established.—A fund to aid needy students in medicine has been established by a group of physicians at the University of Nebraska College of Medicine, Omaha. The charter members are all on the staff of the university. A nonprofit corporation without capital stock, the Nebraska Medical Education Fund, Inc., is "for educational and charitable purposes." Aid will be given regardless of race or creed. The main purpose of the organization is "to help needy and worthy students in medical and health professions to obtain higher education." The corporation has the authority to accept contributions and invest them, borrow money, and pay and obligate itself for any expenses involved. Loans to one student for one academic year may not exceed $1,500. Applications can be obtained from the Student Assistance Committee through the office of the assistant dean. To be a member with full voting rights, one must be licensed to practice medicine in Nebraska. However, honorary members may be named. Officers of the corporation are Dr. Clinton C. Millett, president; Dr. Willson B. Moody, vice-president; and Dr. John R. Schenken, treasurer.

NEW YORK

State Society Convenes in Buffalo.—The Medical Society of the State of New York will hold its 153rd annual convention May 9-15 at the Hotel Statler–Hilton, Buffalo. The annual dinner, at which Dr. Gunnar Gundersen, President, American Medical Association, will be the principal speaker, will take place the evening of May 11. The program will consist of general sessions, sections, exhibits, and films. Symposiums and panel discussions on Surgery in Cardiovascular Disease, Prognosis in Surgically Treated Cancer, Hypnosis in Clinical Practice, and the Role of the General Hospital in the Care of Special Medical Problems are planned.

A session on the History of Medicine is set for May 15, 9 a. m., at which time the section on legal medicine will open. The opening session of the regular annual meeting of the House of Delegates will be convened at 10 a. m., May 9, by the speaker, Dr. Joseph A. Lane, of Rochester. At this session Dr. John D. George Sr., of Verona (Oneida County), will receive the State Medical Society award as "Outstanding General Practitioner of New York State for 1958." At the annual dinner, the president's medal will be awarded to Dr. Leo E. Gibson, of Syracuse. He will be succeeded by Dr. Henry I. Fineberg, of Jamaica (Queens County, New York City).

Report on Health Statistics.—A record 362,000 births were reported in New York during 1958; the death rate, 10.4 per 1,000 population, was the third lowest in the history of the state; the tuberculosis death rate, 8.1 per 100,000 was an all-time low; and mortality from cancer was the lowest in eight years. This information is contained in "New York's Health," the 1958 annual report of the New York State Health Department available for distribution. Dr. Herman E. Hilleboe, state health commissioner, explained that the climb in birth rates and the declining death rates have combined since 1950 to increase the population of the state by 1,500,000 persons, giving impetus to the establishment of full-time county health departments. During the year Monroe, Dutchess, and Chemung counties began operation of such units; seven counties with 100,000-plus populations have yet to do so. Advances cited in the report include the work being done at Roswell Park Memorial Institute and the State Rehabilitation Hospital at West Haverstraw; establishment of a 15-station air sampling network by the Air Pollution Control Board; conducting baseline surveys of natural radiation; further development of the state-wide meat inspection program; activities in the field of environmental sanitation, medical services, and local health service; and the research and service activities of the department's Division of Laboratories and Research.

New York City

Dr. DeVoe Named Department Chairman.—The appointment of Dr. Arthur G. DeVoe as professor and chairman of the department of ophthalmology, Columbia University College of Physicians and Surgeons, was announced March 15. At the same time, the appointment of Dr. DeVoe as attending ophthalmologist and director of the ophthalmology service in Presbyterian Hospital was announced. The appointments are effective July 1, when Dr. John H. Dunnington retires from those posts. Dr. DeVoe was a resident in ophthalmology at the Institute of Ophthalmology at Presbyterian Hospital from 1937 to 1940. He served as an associate in ophthalmology in the College of Physicians and Surgeons from 1940 until 1950, when he became professor and chairman of the department of ophthalmology in the New York University Post-Graduate Medical School.

Personal.—Dr. Nadene Coyne has been appointed coordinator of training for physicians in the department of physical medicine and rehabilitation of New York University-Bellevue Medical Center and director of the Respirator Center at Goldwater Memorial Hospital. She was formerly director of the department of physical medicine and rehabilitation, Cleveland General Hospital, Cleveland.—Dr. James A. Brussel, assistant commissioner, New York State Department of Mental Hygiene, will have his novel, "Just Murder, Darling," published by Charles Scribner's Sons; July release is anticipated. Dr. Brussel is also completing "Psychiatry for the Layman" for Barnes and Noble.—Dr. Alexander B. Gutman, director, department of medicine, Columbia University College of Physicians and Surgeons, delivered the annual John Auer lecture sponsored by Phi Beta Pi medical fraternity, Saint Louis University School of Medicine, March 13.

Visit by Foreign Public Health Physicians.—An international group of 26 graduate physicians pursuing advanced studies in public health at Harvard visited the State University of New York Downstate Medical Center, Brooklyn, March 18 and 20 to observe the teaching and research program in environmental medicine. The group was led by Dr. Brian MacMahon, head, department of epidemiology at Harvard. Representing 13 countries in North and South America, Europe, and Asia, the group included 18 physicians who will be returning to faculty positions in preventive medicine in their own countries as well as eight physicians taking the advanced degree program in epidemiology. For some of the group, the visit to the Downstate Medical Center is part of a "peripatetic seminar" program which will include visits to other preventive medicine teaching centers in the United States, the United Kingdom, Puerto Rico, Yugoslavia, and Lebanon.

Dr. Goldwater Honored.—Dr. Leonard J. Goldwater, professor of occupational medicine, Columbia University School of Public Health and Administrative Medicine, received an award from the President's Committee on Employment of the Physically Handicapped and the New York State Governor's Committee on "Employ the Physically Handicapped" March 19 "for contributions in eliminating prejudice and misinformation regarding the rehabilitation of heart patients." The nomination submitted for Dr. Goldwater cited him for his work in organizing the Cardiac Work Classification Unit at Bellevue Hospital in New York City in

1941. This unit was designed to study employment problems of cardiac patients and to study the effects of employment on heart disease and the effects of heart disease on the ability to work. Dr. Goldwater was installed recently as president of the American Academy of Occupational Medicine. He is a member of the World Health Organization expert advisory panel on social and occupational health and is a consultant to the office of vocational rehabilitation, Department of Health, Education, and Welfare.

Scholarship for Advanced Study Abroad.—In the current year the Committee on Medical Education, New York Academy of Medicine, will award one scholarship grant in the amount of $4,500 for the academic year 1960-1961. This scholarship was established to provide aid for advanced study abroad in a clinical subject in preparation for the practice of medicine or surgery in any of their branches. As stipulated by the donor, candidates must be male interns or residents in voluntary, municipal, or Veterans Administration hospitals in New York City. The course of study, the auspices under which it is to be taken, and the place or places where the study is to be pursued must receive the approval of the committee. Applicants are favored who, from their records, show themselves capable of advanced work in clinical medicine. The committee stipulates that the study be pursued abroad, preferably in Great Britain or in continental Europe. Applications for this scholarship must be submitted by Sept. 1. Candidates may secure application forms by writing: Dr. Robert L. Craig, Executive Secretary, Committee on Medical Education, The New York Academy of Medicine, 2 E. 103 St., New York 29.

NORTH CAROLINA

Appropriations for Public Health.—The Raleigh *News and Observer* has reported that per capita state appropriations for public health in some of the Southern states for 1958 were as follows: Georgia, $1.73; Florida, $1.49; Virginia, $1.27; Kentucky, $0.98; Tennessee, $0.89; South Carolina, $0.85; Mississippi, $0.81; and North Carolina, $0.70. While local health departments in North Carolina were established on a basis whereby the state and county share the expenses equally, it is said that the state has gradually lagged in its support of this work until now the counties bear 77% of the cost, the state only 17%, and the remaining 6% comes from other sources.

Scholarships for Medical Study.—Winners of the second eight Reynolds Scholarships for study at Bowman Gray School of Medicine have been announced by Dr. C. C. Carpenter, executive dean. The scholarships, provided by the A. Smith Reynolds Foundation, are adequate to cover the cost of a medical education, including four years of medical school and two years of postgraduate hospital training. Benefits range from $2,400 to $4,800 a year. Reynolds Scholars are chosen by the Committee on Admissions from residents of North Carolina who are admitted to the next entering class at Bowman Gray. Selection is based on character, scholarship, potential as a physician, and financial need. The recipients must have the intention to practice medicine in North Carolina for at least five years after completing their medical education. The first eight Reynolds Scholars will complete the freshman year at Bowman Gray in June. The second eight will enroll in September.

Conference for Medical Record Personnel.—A Conference on Medical Records will be held April 27-29 at the Duke University Medical Center. Planned for hospital medical record personnel and hospital administrators, the conference will be sponsored by Duke in cooperation with the Association of Medical Record Librarians of North Carolina. The second day of the conference will be designed especially for hospital administrators as well as for medical record personnel. Guest speakers who will join Duke Medical Center staff members in presenting the conference program include Margaret J. Heath, president, American Association of Medical Record Librarians, Buffalo, N. Y.; Howard M. Kline, chief, Education and Training Branch, Division of International Health, U. S. Public Health Service, Washington, D. C.; Margaret C. Doran, chief, Medical Record Library Division, Veterans Administration Department of Medicine and Surgery, Washington, D. C.; Donald Smith, administrative assistant, Medical Education for National Defense, Washington, D. C.; Dr. Robert R. Cadmus, director N. C. Memorial Hospital, Chapel Hill; Sample B. Forbus, administrator, Watts Hospital, Durham; and Margaret L. Russell, president, N. C. Association of Medical Record Librarians, Winston-Salem. The conference will be open to North Carolina and to out-of-state medical record personnel and hospital administrators. For information, write Mrs. Je Harned Bufkin, Medical Record Library, Duke University Medical Center, Durham, N. C.

PENNSYLVANIA

Tuberculosis Meeting in Scranton.—The Pennsylvania Tuberculosis and Health Society will hold its annual meeting in collaboration with the Pennsylvania Trudeau Society, Pennsylvania Chapter, American College of Chest Physicians, and the Pennsylvania Conference of Tuberculosis Workers April 15-17 in Scranton. The meeting is acceptable for five hours of category II credit by the American Academy of General Practice. Dr. David A. Cooper will preside at a "Consecutive Case Conference" the morning of April 16. A discussion, "A New Challenge: Respiratory Diseases," is planned for April 15. Coffee conferences the morning of April 17 will have the following titles and participants:

Tuberculosis, Drs. John S. Packard, Milton, John C. Sanner, Scranton, and Samuel C. Stein, Philadelphia.
Emphysema, Drs. Richard T. Cathcart and Henry P. Close, Philadelphia.
Silicosis, Drs. Ross K. Childerhose, Harrisburg, and Peter A. Theodos, Philadelphia.
Other Acute Respiratory Diseases, Drs. Harold L. Israel and Robert L. Mayock, Philadelphia.

A panel on "Social Implications of a Changing Tuberculous Population" will be conducted the morning of April 16.

Philadelphia

Plan Alumni Publication.—*Medical Affairs,* a new medical alumni and faculty publication has been launched jointly by the School of Medicine and Graduate School of Medicine of the University of Pennsylvania. It will be published four times a year in the spring, summer, fall, and winter. *Medical Affairs* will not be a scientific publication. It will contain editorials by leaders in fields of interest related to medicine, articles by faculty and alumni, news of developments at the schools, news of alumni, book reviews, and activities of the faculty members. More than 14,000 copies will go to Pennsylvania medical alumni in 50 states and around the world. The editorial office of *Medical Affairs* is located at 201 S. 34th St., Philadelphia 4.

Symposium on Structure of Science.—A symposium on "The Structure of Science" will be held April 17-18 accompanying the formal opening of new laboratories and a new museum at the Wistar Institute of Anatomy and Biology. Senator Lister Hill, of Alabama, and Dr. LeRoy Burney, surgeon general, U. S. Public Health Service, will be among the speakers. Mayor Richardson Dilworth will discuss Philadelphia as a center for basic research. The symposium will be held in Irvine Auditorium, University of Pennsylvania, and the institute will be the scene of a reception and a tour of its new laboratories and museum April 18, following the afternoon session. Papers by foreign participants include: "Theories of Tolerance," Dr. Peter B. Medawar, Jodrell professor of zoology, University College, London; "The Structure of Viruses," Dr. Francis H. C. Crick, member of the medical research council's unit for molecular biology at Cavendish Laboratories, Cambridge, England; "Chemical Structure and Biological Function," Dr. H. Gobind Khorana, head of organic chemistry, British Columbia Research Council, University of British Columbia; "The Evolution of Tumor Cell Populations," Dr. George Klein, professor of tumor biology at Karolinska Institute, Stockholm, Sweden. The Wistar Institute was founded in 1818 as the Wistar Museum. The museum was expanded into a biological research institute in 1892 in consequence of gifts from Gen. Isaac J. Wistar, grand-nephew of the founder. The Wistar Institute of Anatomy and Biology was formally opened in 1894. The original institute building has been completely reconstructed during the past two years to provide new laboratories and a new museum.

TENNESSEE

Grant for Brain Research.—One million dollars for a five-year study on prevention of brain damage has been awarded to the University of Tennessee College of Medicine by the National Institute of Neurological Disease and Blindness, U. S. Public Health Service. Announcement of the largest grant the medical units have ever received was made by Dr. O. W. Hyman, vice-president in charge of the medical units, and Dr. Maston K. Callison, dean of the college. Funds will be available at the rate of more than $200,000 per year. Dr. James G. Hughes, professor of pediatrics, will be principal investigator, and Dr. Phillip C. Schreier, professor of obstetrics and gynecology, co-investigator. The Memphis study will involve close cooperation between several departments in the college. More than 40 people will be on the research team. About 750 women and their babies in units of City of Memphis Hospitals will be studied for five years. The local project is part of a collaborative effort in which 15 medical schools in the nation will participate, simultaneously collecting information on causes of brain damage. Information from the schools will be pooled, and it is expected that by the end of five years the schools will have studied more than 60,000 pregnant women and their offspring.

Annual Meeting in Memphis.—The 124th annual meeting of the Tennessee State Medical Association will be held April 12-15 in Memphis, with headquarters at the Peabody Hotel. Guest speaker at the president's banquet, April 13, 7 p. m., with Dr. James C. Gardner, president, presiding, will be Robert J. Farley, LL.B., dean of the School of Law, University of Mississippi, Oxford. At the General Practice Day session that day, a symposium, "Peripheral Vascular Disease—Its Management," will be moderated by Dr. Harwell Wilson. Special society meetings will be held each day. Papers by out-of-state speakers to be presented at the general sessions are as follows:

The Role of the Anesthesiologist in the Practice of Medicine, Dr. Scott M. Smith, Salt Lake City, Utah.
Antibiotic Resistant Staphylococcic Disease, Dr. William Sandusky, Charlottesville, Va.
The Pathology of Low Back Pain, Dr. Walter C. J. Putschar, Washington, D. C.
Infertility—A Family Unit Problem, Dr. William H. Masters, St. Louis.
The Newer Oral Antidiabetic Agents, Dr. Rachmiel Levine, Chicago.

A second symposium, "Diuretics," is scheduled for the morning of April 14. Scientific and technical exhibits are planned. For information, write the Tennessee State Medical Association, 112 Louise Ave., Nashville 5, Tenn.

TEXAS

Annual State Meeting in San Antonio.—The 92nd annual session of the Texas Medical Association will be held April 18-21 in San Antonio, with headquarters at the Hilton Hotel. Among the papers to be presented are "Abnormal Uterine Bleeding at or After the Menopause," Dr. Newell W. Philpott, Montreal, Canada, professor of obstetrics and gynecology, McGill University Faculty of Medicine, and "Land of the Free and Easy," by Dr. Gunnar Gundersen, La Crosse, Wis., President, American Medical Association. Other guest speakers include the following:

Drs. Walter C. Alvarez and Edward I. Compere, Chicago; George C. Andrews, John M. McLean, and Byron Smith, New York City; Harry E. Bacon and James E. Eckenhoff, Philadelphia; Richard J. Bing, St. Louis; Murray M. Copeland and Oscar B. Hunter Jr., Washington, D. C.; John B. Erich, Rochester, Minn.; Jack R. Ewalt, Donald D. Matson, Duncan E. Reid, and Kenneth W. Warren, Boston; Grace A. Goldsmith, New Orleans; Eugene A. Hargrove, Raleigh, N. C.; Herman E. Hilleboe, Albany, N. Y.; Ted F. Leigh, Atlanta, Ga.; Champ Lyons, Birmingham, Ala.; Mitchell I. Rubin, Buffalo, N. Y.; O. A. Sander, Milwaukee, Wis.; and John T. Sessions Jr., Chapel Hill, N. C.

Section meetings, motion picture sessions, and scientific and technical exhibits are arranged. The annual golf tournament will be held April 20. President of the Texas Medical Association is Dr. Howard O. Smith, Marlin. For information write Mr. C. L. Williston, 1801 N. Lamar Blvd., Austin, Texas, Executive Secretary.

GENERAL

Award for Work on Obstetrics or Gynecology.—The Central Association of Obstetricians and Gynecologists is offering an award of $250 for outstanding investigative or clinical work in obstetrics or gynecology. Any accredited physician, research worker, or medical student living within the geographic confines of the Association is eligible. Papers must be written expressly for this competition and must be original. The winning paper will be presented at the annual meeting Sept. 24-26 in Chicago. Manuscripts should be submitted to the secretary in triplicate, accompanied by an abstract not to exceed 150 words. No author's identification shall be shown on any of the three copies, the only identification being a covering letter addressed to the secretary. Papers should be in the hands of the secretary by June 25 and should be addressed to: Dr. Edwin J. DeCosta, Secretary, Central Association of Obstetricians and Gynecologists, 104 S. Michigan Ave., Suite 615, Chicago 3.

Urological Meeting in Atlantic City.—The 54th annual meeting of the American Urological Association, Inc., will be held April 20-23 at the Chalfonte-Haddon Hall, Atlantic City, N. J., under the presidency of Dr. Adolph A. Kutzmann, Los Angeles, who will present the presidential address the afternoon of April 22. Over 25 papers are scheduled for presentation with discussions following. Dr. Hans J. Klapproth, Cleveland, will present "Distribution of Renal Arterial Circulation in the Dog" the morning of April 21 as the first prize essay contest lecture. A program of motion pictures and scientific and technical exhibits are arranged. The Ramon Guiteras Lecture, "Explants of Genito-Urinary Tissues Cultivated for Experimental Studies," will be given by C. M. Pomerat, director, Tissue Culture Laboratory, University of Texas Medical Branch, Galveston. Panel discussions on "Carcinoma of the Bladder" and "The Prostatic Nodule" are arranged. Dr. Einar Ljunggren, Goteborg, Sweden, will present "Some Aspects of Renal Tumors" the afternoon of April 23.

Experimental Biology Meeting in Atlantic City.—The 43rd annual meeting of the Federation of American Societies for Experimental Biology will be held in Atlantic City, N. J., April 13-17. The federation is comprised of the American Physiological Society, the American Society of Biological Chemists, the American Society for Experimental Pathology, the American Society for Pharmacology and Experimental Therapeutics, the American Institute of Nutrition, and the American Association of Immunologists. Headquarters hotel for the federation will be the Traymore. An opening joint session will be held April 14, 8 p. m., under the title "The Biological Significance of the Fine Structure of Macromolecules," with Dr. Francis H. C. Crick, Cambridge, England, as chairman, and including a paper by Dr. J. C. Kendrew, Cavendish Laboratory, Cambridge, England, on "Structure and Function in Myoglobin and Other Proteins." Intersociety sessions under the titles "Physiology and Drug Actions," "Nutritional Requirements of Animal Cells Cultivated in Vitro," and "Neurochemistry" (two sessions) will include the following section titles: Neurochemistry, Atherosclerosis, Blood Clotting, Tissue Culture, Cytology, Neuropharmacology, and Radiation. A program of motion pictures will be presented April 13. Industrial scientific exhibits are planned.

World Conference on Medical Education.—Plans for the second World Conference on Medical Education, to be held in Chicago Aug. 29-Sept. 4, were discussed recently. The seven-day conference, sponsored jointly by world medical bodies, including the World Medical Association, is arranged "to provide a common ground for the free exchange of scientific information and experiences between countries." Collaborating with the W. M. A. in sponsoring the conference are the World Health Organization, the Council for International Organizations of Medical Sciences, and the International Association of Universities. President Eisenhower, who helped organize the National Fund for Medical Education, is patron of the conference. Serving as conference president will be Dr. Raymond B. Allen, chancellor, University of California, Los Angeles. To be held in the Palmer House, the conference will have 125 speakers from about 50 countries, and all business, including lectures, will be translated simultaneously into English, French, and Spanish. "Medicine—A Lifelong Study" is the conference theme. For information write Mrs. Clara Lewinter, World Medical Association, 10 Columbus Circle, New York 19.

Meeting in Chicago to discuss plans for the second World Conference on Medical Education were (left to right): Dr. W. C. Bornemeier, Chicago; Dr. Glen R. Shepherd, assistant secretary, Council on Medical Education and Hospitals, A. M. A.; Miss Margaret Natwick, executive assistant, W. M. A.; Thomas R. Gardiner, co-chairman of the technical exhibits; Dr. Robert A. Moore, dean, College of Medicine in Brooklyn, State University of New York; Dr. George F. Lull, retired secretary and general manager, A. M. A.; Dr. Myron E. Wegman, secretary general, Pan American Sanitary Bureau; Mrs. Clara Lewinter, executive secretary of the conference; Dr. Victor Johnson, director, Mayo Foundation for Medical Education and Research; and Dr. Louis H. Bauer, Secretary General of the World Medical Association.

Government Awards for Lecturing and Research.—U. S. Government Awards for 1960-61, authorized by Public Law 584, 79th Congress, The Fulbright Act, under the auspices of the Board of Foreign Scholarships and the Department of State, were announced. These awards are available for university lecturing and for advanced research in Latin America (Argentina, Brazil, Chile, Colombia, Ecuador, Peru); South and Southeast Asia (Burma, India, Pakistan, Philippines, Thailand); and Pacific Area (Australia, New Zealand). Eligibility includes U. S. citizenship; at least one year of college or university teaching experience (for lecturing); a doctoral degree for research or recognized professional standing (candidates for the degree should apply to the Institute of International Education, 1 E. 67th St., New York City); in some cases, a knowledge of the language of the host country. Awards will be tenable in one country, usually for an academic year, and payable in currency of host country. Round-trip travel for the grantee will be provided but not for members of his family. A maintenance allowance to cover ordinary living expenses of the grantee and his family while in residence abroad and a small incidental allowance for travel, books, and services required in performance of assignment will be given. Closing date of application is April 25. For application forms and information write: Conference Board of Associated Research Councils, Committee on International Exchange of Persons, 2101 Constitution Ave., Washington 25, D. C.

Psychiatrists Meet in Philadelphia.—The American Psychiatric Association will hold its 115th annual meeting at Convention Hall Auditorium in Philadelphia April 27-May 1. Dr. Francis J. Gerty, Chicago, president of the association, will call the meeting to order the morning of April 27. Over 160 papers will be presented, including the following by foreign authors:

A Cross-Cultural Approach to Mental Illness, Dr. Eric D. Wittkower and J. Fried, Ph.D., Montreal, Canada.
Further Developments in the Day Hospital, Dr. T. J. Boag, Montreal.
The Practice of Psychiatry in England Under the National Health Service, Dr. A. Spencer Paterson, London.
A Family Programme for First Year Medical Students, Dr. J. S. Tyhurst, Vancouver, British Columbia.
Socio-Economic Factors in Discharge of Long-Term Mental Hospital Patients, Dr. Gordon O. Patton, Quebec, Canada.
Types of Marital Complementarity and Emotional Health of Children, Dr. Nathan B. Epstein and William A. Westley, Ph.D., Quebec.
A Follow-Up Study of Two Groups of Veterans: (a) Five Years (b) Ten Years, Treated with Sub-Coma Insulin at a Montreal Veterans Hospital, Dr. Harry Grauer, Montreal.

Two dozen evening round-table meetings are planned. Dr. Karl A. Menninger, Topeka, Kan., will give the Academic Lecture. The Adolf Meyer Research Lecture will be given by Dr. W. Grey Walter, Bristol, England. For information, write the American Psychiatric Association, 1700 18th St., N. W., Washington 9, D. C.

Meeting of Physicians in Chicago.—The American College of Physicians will meet April 20-24, with headquarters at The Conrad Hilton Hotel, Chicago, Dr. Eliot E. Foltz of Winnetka, Ill., general chairman, announced. The presentation will include more than 100 papers, 23 panels, clinics at 13 hospitals, 6 clinical-basic science case conferences, 12 color television clinics, 31 clinical investigation reports, 18 scientific exhibits, and a technical exhibit. In the morning, two-hour clinics will be held in the hospitals, followed by panels in the hotel and in the Blackstone and Eighth Street Theaters. At the same time, clinical-basic science case reports will be held in the hotel. A new feature will be a public meeting to which business, civic, and nonmedical professional leaders will be invited. A panel will discuss "The Care and Preservation of the American Executive." The panelists will be Drs. Philip S. Hench, Henry L. Bockus, William C. Menninger, Chester M. Jones, Sara M. Jordan, Howard P. Lewis, Irvine H. Page, and Walter L. Palmer. Dr. Dwight L. Wilbur, of San Francisco, president of the college, will be moderator. The annual business meeting will be held April 23. Officers, regents, and governors will be elected. Dr. Howard P. Lewis, of Portland, Ore., will be inducted as president to succeed Dr. Wilbur. The annual convocation, will be held the evening of April 22, and will include an address by Dr. Wilbur. For information, write Mr. E. R. Loveland, Executive Director, The American College of Physicians, 4200 Pine St., Philadelphia 4.

International Committee on Aging Problems.—An International committee to exchange with foreign countries information about health and welfare programs for older people was established by the National Committee on the Aging. Chairman of the international committee is Dr. Michael M. Dacso, director, physical medicine and rehabilitation, Goldwater Memorial Hospital, New York City. The committee's first task will be to exchange information and experience with leaders of health and welfare programs for older people in Europe and Asia. The National Committee on the Aging, a standing committee of the National Social Welfare Assembly, is a national resource for planning, information and consultation in the field of aging. It is a nonprofit organization.

FOREIGN

Veterinary Congress in Madrid.—The 16th International Veterinary Congress will be held May 21-27 in Madrid, Spain, at the Faculty of Medicine, University City. Two general subjects are planned: "Social Mission of the Veterinary Science and Practice" and "Nuclear Energy and Veterinary Sciences." Section titles are as follows:

Veterinary Medicine.
Epizootology.
Veterinary Public Health.
Zootechnics.
Veterinary Profession.

A program of films, excursions, receptions, and a ladies' program are planned. The official languages will be Spanish, French, English, and German, and simultaneous translation will be provided. For information write the 16th International Veterinary Congress, 11, Villanueva Street, Madrid, Spain.

Symposium on Bacterial Resistance.—On May 1-3 a symposium on the Prevention of Bacterial Resistance to Antibiotics in Obstetrics and Gynecology will be held in Perugia, Italy, sponsored by the Italian Society of Obsterics and Gynecology. The symposium, to be held at the University of Perugia, will have the following session titles:

Problems Relating to Bacterial Resistance in a Maternity Hospital.
  (a) Resistant organisms in the wards of an obstetrical and gynecological service.

- (b) The problem of bacterial resistance and infections in obstetrics and gynecology.

Suggestions for the Prevention of Bacterial Resistance.

- (a) Extension and limitations in the prophylactic use of antibiotics and chemotherapeutics (operative vaginal deliveries, caesarian sections, infected abortions and labors, gynecological operation, etc.).
- (b) Reserved antibiotics in safe-keeping. Their use in emergency cases.
- (c) Nonantibiotics and analogous drugs as prophylactic and therapeutical agents in infected cases in obstetrics and gynecology.

Conclusions.

No fees are required for registration. Simultaneous interpretations will be provided in Italian and English, and proceedings will be recorded for publication. A ladies' program and entertainment schedule are planned. Correspondence should be addressed to: Segreteria del Simposio, Clinica Ostetrics e Ginecologica dell'Università, Policlinico, Perurgia, Italy.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications is July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral.* For candidates in the Midwest. Chicago, April 15-18. Final date for filing application was Jan. 1. *Oral.* For candidates on the West Coast. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. *Examination in the Subspecialties. Gastroenterology.* Philadelphia, April 17-18. Final date for filing application was Feb. 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *I. Oral and Clinical.* Chicago, May 8-19. Formal notice of the exact time of each candidate's examination will be sent him in advance of the examination dates. Candidates who participated in the Part I examinations will be notified of their eligibility for the Part II examinations as soon as possible. Deadline for receipt of new and reopened application for the 1960 examinations is Aug. 1, 1959. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Oral.* Philadelphia, June 2-6; St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 19-21, 1960. The deadline for the receipt of application is Aug. 15, 1959. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application is April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Boston, April 16-19. Final date for filing application was Feb. 28. Sec., Dr. Edward B. Smith, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application was February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Preventive Medicine: *Public Health.* Minneapolis, Boston, Baltimore, Chapel Hill, North Carolina and New Orleans, April 9-11; Berkeley, Calif., April 23-25; Pittsburgh, April 16-18. *Occupational Medicine.* Chicago, April 24-26. *Aviation Medicine.* Los Angeles, April 24-26. Final date for filing all applications is March 16. Sec., Dr. Tom F. Whayne, 3438 Walnut St., Philadelphia 4.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application is March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: New Orleans, Mar. 16-17; Chicago, Oct. 19-20; New York, Dec. 14-15. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Examination.* Chicago, June 2-4. If needed a special examination will be offered at this time in Nuclear Medicine to diplomates in Radiology or Therapeutic Radiology. The deadline for filing applications is April 1. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. *Part II.* San Francisco, April 13-14; Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 1959. Final date for filing application is July 1. *Oral.* September. Final date for filing application is July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. Final date for filing application is Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

GOVERNMENT SERVICES

ARMY

Personal.—Brig. Gen. Perrin H. Long of Brooklyn, N. Y., has transferred to the Retired Reserve. He began his military career in the ranks during World War I. After receiving a direct appointment as lieutenant colonel in August, 1942, he served on active duty in North Africa and Europe as a medical consultant. He completed more than 18 years of active and reserve service; his last assignment prior to retiring was mobilization designee as a special assistant to the Surgeon General.

NAVY

Film Certificate Awarded.—The Navy received an Edinburgh International Film Festival certificate for a Bureau of Medicine and Surgery film entitled "Color Vision Deficiencies." The certificate was presented by British Ambassador Sir Harold Caccia in March. The Edinburgh Festival is an annual event. Over a period of 15 years, the Navy has been given about 34 national and international awards for its motion pictures. "Color Vision Deficiencies" (MN 8246) is a 16-mm. color film with sound. The running time is 20 minutes. It is intended for medical department personnel who are responsible for color vision tests.

Captain Shone Elected.—Capt. Lloyd B. Shone, Medical Corps, U. S. Navy, was elected secretary of the American Academy of Occupational Medicine at the Academy's 11th Annual Meeting in Boston in February. He is presently director of the Occupational Medicine and Dispensary Division in the Bureau of Medicine and Surgery and is certified as a specialist in occupational medicine by the American Board of Preventive Medicine.

VETERANS ADMINISTRATION

Dr. Middleton Reappointed.—Dr. William S. Middleton was reappointed for a second four-year term as chief medical director of the Veterans Administration. As VA chief medical director, he heads the agency's 171 hospitals, nearly 100 outpatient clinics, and nationwide hometown medical services, which together provide care for about 2,500,000 patients yearly.

PUBLIC HEALTH SERVICE

Embryology Committee.—An experimental Embryology and Development Training Committee was appointed by the surgeon general. It held its first meeting at the Harvard Medical School in February. Under the chairmanship of Dr. Louis Bellman, professor and chairman of obstetrics and gynecology at the State University of the New York School of Medicine, the committee will review training grant applications in experimental embryology and related basic sciences. It will function under Dr. G. Halsey Hunt, chief of the division of general medical sciences, and Dr. Frederick L. Stone, assistant division chief and chief of the research training branch. Dr. Howard P. Jenerick will be executive secretary. The work of the committee, which is made up of members representing many of the basic specialties related to human reproduction and development, will help meet the increasing need for emphasis on research training in these fields. The program will support research training for postresidents or other postdoctoral and predoctoral trainees in electron microscopy, genetics, developmental physiology, neonatal pathology, fetal biochemistry, and other related basic science fields. In addition to Dr. Hellman, members of the committee include Drs. Robert A. Aldrich, University of Washington School of Medicine, Seattle; Harry H. Gordan, Sinai Hospital, Baltimore; Duncan E. Reid, Boston Lying-in Hospital, Boston; Howard C. Taylor, Columbia-Presbyterian Medical Center, New York; and James G. Wilson, University of Florida College of Medicine, Gainesville, Fla.

Training in Epidemiology.—A course in applied epidemiology will be offered at the Communicable Disease Center in Atlanta, Ga., May 4-8, 1959, as a part of the continuing program of the center's training branch. This course is designed primarily for physicians who serve as investigators of disease outbreaks or have administrative responsibility for such investigations. It serves both as a refresher course for the experienced health administrators and as an introductory course for physicians new to public health. Emphasis is placed on developing and understanding of how epidemiologic techniques can be used in the approach to the solutions of problems in the preventable disease field. Lecture-discussion sessions and audiovisual aids are used in the presentations, but emphasis is placed on group participation, which is obtained through group solution of epidemiologic problems, seminar-type presentations, and panel discussions. Registrants will be expected to attend all sessions of the course. Further information and application forms may be obtained from: Chief, Communicable Disease Center, Public Health Service, 50 Seventh St. N. E., Atlanta 23, Ga., Attention: Chief, Training Branch.

DEATHS

Owen, Abraham Miconias Ⓜ Bloomington, Ind.; Indiana University School of Medicine, Indianapolis, 1940; veteran of World War II; associated with Bloomington Hospital; died Jan. 12, aged 58.

Pennell, Samuel, Brooklyn; Cornell University Medical College, New York City, 1926; veteran of World War II; on the staffs of the Jewish and Maimonides hospitals; specialist certified by the American Board of Pathology; died Jan. 1, aged 58.

Potter, Joseph Lumbard Ⓜ Duke Center, Pa.; Medico-Chirurgical College of Philadelphia, 1916; died Dec. 22, aged 65.

Rogers, Charles Lewis Ⓜ Norman, Okla. (licensed in Oklahoma by years of practice); died in a hospital at Bartlesville Jan. 26, aged 82.

Rose, Joseph Everett Ⓜ Pensacola, Fla.; University of Alabama School of Medicine, Mobile, 1909; died Dec. 28, aged 79.

Scott, James Stanley, Pomona, Calif.; University Medical College of Kansas City, Mo., 1896; died Dec. 17, aged 92.

Shipper, Philip Marvin, New York City; Indiana University School of Medicine, Indianapolis, 1934; served on the staffs of the Cornell Medical Center–New York Hospital and Beth David Hospital; died in the New Rochelle (N. Y.) Hospital Dec. 24, aged 48.

Siminson, Irwin Dave Ⓜ Mineral Point, Wis.; Rush Medical College, Chicago, 1924; for many years practiced in Chicago, where he was on the staff of the Mercy Hospital and chief surgeon with the New York Central Railroad; died Jan. 26, aged 63.

Skinner, James Edwards, Tacoma, Wash.; Rush Medical College, Chicago, 1896; for many years a medical missionary in China; died in Battle Ground Jan. 12, aged 91.

Sonnenschein, Joseph Benjamin Ⓜ Chicago; Rush Medical College, Chicago, 1902; veteran of World War I; for many years connected with the city board of health; died in the Chicago Wesley Memorial Hospital Jan. 30, aged 82.

Stalker, John Morton, Borden, Ind.; University of Louisville (Ky.) Medical Department, 1906; served as trustee of the Borden Schools; on Thanksgiving Day in 1957 Borden proclaimed "Dr. Stalker Day" at the Borden High School; died Jan. 10, aged 76.

Staples, Mary Morrison, San Francisco; University of California School of Medicine, San Francisco, 1894; died Jan. 14, aged 98.

Stapp, Roth Van Allen, Houston, Texas; St. Louis University School of Medicine, 1930; veteran of World War II; died Jan. 19, aged 53.

Stevenson, Holland Newton Ⓜ Pelham, N. Y.; born in Pittsfield, Mass., in 1886; Johns Hopkins University School of Medicine, Baltimore, 1912; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; formerly on the faculty of his alma mater, Columbia University College of Physicians and Surgeons in New York City, Creighton University School of Medicine in Omaha and at the New York Post-Graduate Medical School and Hospital in New York City; associated with the New Rochelle (N. Y.) Hospital; a director of the National Bank of Westchester; died Jan. 11, aged 72.

Swart, William Sheridan Ⓜ Girard, Kan.; Barnes Medical College, St. Louis, 1899; died Dec. 19, aged 83.

Swenson, Henning Melville Ⓜ Chicago; University of Illinois College of Medicine, Chicago, 1929; veteran of World War I; on the staff of the Augustana Hospital for many years; died Jan. 17, aged 58.

Taubenhaus, Matthew Ⓜ Chicago; born in Warsaw, Poland, Nov. 29, 1903; Medizinische Fakultät der Universität, Vienna, Austria, 1928; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the Endocrine Society, Chicago Society of Internal Medicine, Society of Experimental Biology and Medicine, American Diabetes Association, New York Academy of Sciences, and the American Association for the Advancement of Science; in 1952 a Claude Bernard visiting professor at the University of Montreal; in March, 1939, came to the United States and began his association with Michael Reese Hospital; first in the department of metabolic and endocrine research and then in the department of medicine; at the time of his death, was attending physician at the hospital and vice-chairman of the department of medicine; died Jan. 16, aged 55.

Ⓜ Indicates Member of the American Medical Association.

Traweek, Albert Carroll Sr. Ⓜ Matador, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1901; member of the American Academy of General Practice; for many years county health officer; superintendent of the Traweek Hospital, of which he was the owner; died in the Quanah (Texas) Memorial Hospital Jan. 10, aged 83.

Troncoso, Manuel Uribe Ⓜ New York City; born June 17, 1867; Universidad Nacional Facultad de Medicina Mexico, D. F., 1890; specialist certified by the American Board of Ophthalmology; served as professor of ophthalmology at the New York Post-Graduate Medical School and Hospital and assistant professor of clinical ophthalmology at the Columbia University College of Physicians and Surgeons; in 1942 received the research medal of the American Medical Association Section on Ophthalmology; author of "A Treatise on Gonioscopy"; wrote "Internal Diseases of the Eye and Atlas of Ophthalmoscopy," which has gone through many editions; died in the Frances Schervier Home and Hospital Jan. 21, aged 91.

Underwood, Felix Joel Ⓜ Jackson, Miss.; born in Nettleton, Nov. 21, 1882; Memphis (Tenn.) Hospital Medical College, 1908; began his public health career in 1918 as health officer for Monroe County and served until 1921; in the latter year came to Jackson and became director of the Bureau of Child Hygiene for the Mississippi State Board of Health, serving until 1924, when he became executive officer and secretary and held that post until his retirement in June, 1958; served as president of the American Public Health Association; twice was the recipient of the Lasker Award; received it first in 1945 for his planned parenthood program, and again in 1953 for outstanding public health administration; in 1941 president of the Southern Branch of the American Public Health Association and served as chairman of the regional executive board and member of the governing council; past-president of the Southern Medical Association, Mississippi Public Health Association, Conference of State and Provincial Health Authorities of North America, Mississippi State Medical Association, State Conference of Social Work, and the State Board of Examiners for Nurses; from 1912 to 1925 secretary of the Northern Mississippi Thirteen Counties Medical Society; director at large, National Tuberculosis Association from 1942 to 1944; served as a member of the board of directors of the American Cancer Society and recipient of a plaque as an award for meritorious service as campaigning chairman for the state division in 1948; member of the House of Delegates of the American Medical Association from 1933 to 1946 and from 1949 to 1951; general chairman of the Mississippi Council for Child Health and Protection; member of the State Board of Public Welfare from 1933 to 1935; delegate to several congresses and conferences; specialist certified by the American Board of Preventive Medicine, of which he served as vice-chairman; associate in public health, University of Mississippi School of Medicine; guest lecturer, Tulane University in New Orleans and Meharry Medical College in Nashville, Tenn.; special consultant to the surgeon general, U. S. Public Health Service, and to the National Advisory Mental Health Council; fellow of the American College of Physicians; for three years served as a member of the board of scientific directors of the Rockefeller Foundation in New York City; for many years member of the board of directors of the Standard Life Insurance Company; member of the staffs of the Mississippi Baptist, St. Dominic, and Mississippi State Charity hospitals; secretary of the board of trustees of the Mississippi State Tuberculosis Sanatorium; member of the state commission on hospital care; member and past-president of the board of trustees of the Mississippi Children's Home Society; for many years state fund raising chairman of the National Foundation for Infantile Paralysis; also served in an executive capacity for numerous other community and health organizations; a state building was named in his honor; in 1950 received the Arthur T. McCormack Award; in the last three weeks of his life, received two top accolades for service to his state; United Press International newspaper, TV, and radio editors named him "1958 Man of the Year"; winner of the new University of Mississippi–First Federal Foundation "Missy" award for distinguished service; the *Mississippi Doctor* for September, 1944, was designated the Underwood issue in his honor; the journal carried many tributes for him and a review of the health of the state under his direction; joint author of "History of Public Health and Medical Licensure," Vol. I, 1798-1937, Vol. II, 1938-1947; died Jan. 9, aged 76.

Vander Veer, Albert Ⓜ Charlotte, N. C.; Columbia University College of Physicians and Surgeons, New York City, 1904; specialist certified by the American Board of Internal Medicine; practiced in New York City for many years and was associated with the Roosevelt Hospital; veteran of World War I; past-president of the American Academy of Allergy; died in the Presbyterian Hospital Jan. 31, aged 79.

Vorpahl, Rudolph Augustus Ⓜ Cedar Rapids, Iowa; Milwaukee Medical College, 1905; veteran of World War I; for many years county coroner; died Jan. 14, aged 78.

FOREIGN LETTERS

AUSTRIA

Icterus Neonatorum.—At the meeting of the Society of Physicians in Vienna on Jan. 30, Dr. H. Gross stated that the most important form of icterus in the newborn infant is the icterus gravis associated with erythroblastosis fetalis. Patients with this type of icterus must be given exchange blood transfusions to prevent early death or permanent damage because of kernicterus resulting from hyperbilirubinemia. Other diseases to be considered in the differential diagnosis include epidemic hepatitis; the rare homologous serum hepatitis; congenital cirrhosis of the liver; acute yellow atrophy; occlusion of bile ducts by aplasia, artresia, stenosis due to choledochus cysts or adhesions, or thickened bile; general sepsis; congenital syphilis; toxoplasmosis; cytomegaly; listeriosis; occasionally diabetes mellitus, a prediabetic condition of the mother or a toxemia of pregnancy; and rarely cystic fibrosis of the pancreas. Administration of large doses of vitamin K may also lead to hyperbilirubinemia. One may observe a prolonged icterus also in children with congenital thyroid deficiency. In addition a severe, long-continued icterus frequently occurs in premature infants and is due to a functional immaturity of the liver. Exchange blood transfusions may be considered for the prevention of kernicterus in patients with a rise of the indirect bilirubin serum level to more than 20 mg. per 100 cc.

Pheochromocytoma.—At the meeting of the Society of Physicians in Vienna, on Jan. 6, Drs. O. Kraupp and H. Bernheimer stated that a greatly increased excretion of pyrocatechin is pathognomonic of a pheochromocytoma. A slightly increased renal excretion of epinephrine does not, however, rule out the presence of a chromaffin tumor. The speakers confirmed the diagnostic significance of the 3-methoxy-4-hydroxymandelic acid excreted in the urine of a patient with a tumor secreting levarterenol and epinephrine. The symptoms disappeared and the amount of pyrocatechin excretion, which was high in the beginning of observation, dropped within a few weeks; but the 24-hour excretion of the mandelic acid derivative remained high and assured the diagnosis of pheochromocytoma. In this case the *p*- and m-hydroxyhippuric acid excretion was also greatly increased. After excision of the tumor the excretion of the abovementioned acids decreased to normal. The speakers hoped that by determining the renal excretion of the decomposition products of pyrocatechin the differential diagnosis of a suspected chromaffin tumor would be improved.

BRAZIL

Postoperative Sodium and Potassium Metabolism.—Dr. J. de Moraes and co-workers, of the Rio de Janeiro Hospital São Miguel, (*Rev. brasil. cir.* 36:137, 1958) studied the metabolism of sodium and potassium in 20 patients, 18 of whom had had gastrointestinal operations and 2 of whom had had operations on the respiratory tract. Water, sodium chloride, and potassium balance studies were made on all patients for eight days, as well as determinations of electrolytes in the plasma on the first, third, and fifth postoperative days. The authors concluded that in the immediate postoperative period there is a low output of sodium in the urine with paradoxical low level of plasma sodium. In this period sodium must be given carefully and the extrarenal salt loss through vomiting, fistulas, and gastric and jejunal aspiration should be compensated in accordance with the amount lost.

When the urinary sodium retention and the hyponatremia last for more than eight days, in spite of adequate replacement, operative complications should be looked for and treated, instead of concentrating on the hyponatremia. An increased output of urinary potassium in the immediate postoperative period and discreet hypopotassemia during the third and fifth postoperative days were observed. This increase in potassium excretion is due in part to the adrenergic corticoid phase. In patients who have taken nothing by mouth for five or more days there may be a depletion of potassium with evident symptoms, abnormalities in the electrocardiogram, and, less frequently, hypopotassemia. If a long period of no oral intake is foreseen, the administration of potassium should be started from the first day, to avoid depletion. In dehydrated patients the potassium replacement must be preceded by rehydration to insure a good output of urine.

Cyanosis in Schistosomiasis.—Dr. J. V. Barbas and co-workers, at a meeting of the Associação Paulista de Medicina reported a case of hepatosplenic schistosomiasis due to Schistosoma mansoni in which the patient showed, during the last part of his illness, dyspnea on exertion and an intense and progressive cyanosis. Physical examination of the lungs, roentgenograms of the chest, and an electrocardiogram

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

showed no abnormalities. Functional tests of the lungs suggested the presence of a pulmonary arteriovenous fistula. This was confirmed by angiocardiography. Cardiac catheterization showed normal pressure in the pulmonary artery and an increased cardiac output. The pulmonary biopsy specimen showed the presence of schistosomes and of several fistulas between the small branches of the pulmonary artery and the pulmonary veins. These fistulas were caused, as demonstrated in a previous investigation by one of the authors, by schistosome ova. The dyspnea and cyanosis were caused by these arteriovenous microfistulas. The authors believed this to be the first reported case of pulmonary schistosomiasis in which, in the absence of cor pulmonale diagnosed during the life of the patient, marked cyanosis was present in addition to the usual symptoms of hepatosplenic schistosomiasis.

Blastomycosis.—Dr. R. M. Castro and co-workers of the São Paulo State University Hospital (*Rev. paulista med.* 53:479, 1958) drew attention to the great difficulties of the diagnosis in some patients with Brazilian blastomycosis and illustrated the problem with the report of eight typical cases. As a rule, this disease does not present diagnostic difficulties, as its two common forms—the mucocutaneous and the lymphaticovisceral—present pathognomonic signs and their lesions abound in Blastomyces brasiliensis. Difficulties arise, however, when the process remains restricted to the lymph nodes without a tendency to softening and fistulization or because localized in deep organs without tegumentary manifestation, or when the tegumentary lesion is so small that it escapes discovery. Without the demonstration of the parasite, and the lesions clearly simulating those of other diseases, the diagnosis is sometimes difficult. Of the eight cases presenting diagnostic difficulties two resembled Hodgkin's disease and the diagnosis was established only after lymph node biopsy; three which could be classified as an icteric form had a bout of obstructive jaundice caused by compression of the biliary ducts by masses of enlarged lymph nodes and the diagnosis was made at operation; one simulating a severe hemopathy was diagnosed only at autopsy; one died before a diagnosis could be made and was diagnosed at autopsy; and one simulating adrenocortical hypofunction also could be diagnosed only at autopsy.

An early and accurate diagnosis is of the utmost importance because specific treatment can now cure what is otherwise a highly fatal disease. Aside from identification of the causative organism, laboratory tests are of little value. Hyperglobulinemia, however, suggests a granulomatous process. This may give a valuable clue in cases simulating a neoplastic or leukemic process, since in those conditions hyperglobulinemia does not occur.

FINLAND

The Training of Specialists.—Last summer representatives of the Scandinavian Medical Associations met in Ulvik to discuss, among other things, postgraduate study and the training of specialists. Dr. Kosonen, of Finland, pointed out that before 1932 no organization had had authority to confer on physicians the title of specialist. Since then the committee created by the Finnish Medical Association for this purpose has issued rules which have needed revision from time to time so as to reflect the most recent experiences in this sphere. By now there are 37 fields in which a physician may qualify as a specialist, but there are only 14 main specialties. Broadly speaking, the specialist must have a year of ordinary postgraduate training plus three years of some special subject studied at a teaching hospital. Hitherto he has not been required to pass any special examination on his specialty, and his qualifications have not been scrutinized by any disciplinary body. Of late there has been a controversy over the creation of a new board of examiners of candidates for the title of specialist, with the public health authorities, the medical faculties, and the Finnish Medical Association pulling in different directions. Dr. Kosonen would like to see the standards of specialty training in Finland brought closer to the level of the other Scandinavian countries. For the present this would require study in medical centers outside Finland.

Pediatric Surgery.—Dr. M. Sulamaa, of the Helsinki Childrens Clinic, recommended that operations on children be performed in a children's rather than a general hospital (*Nordisk medicin,* Dec. 18, 1958). His study for the period 1947 to 1957 includes a wide range of cases which he classes as general, septic, urologic, thoracic, orthopedic, or neurological surgery and tumors. In each of these spheres he would like to see the development of pediatric surgery always within the framework of a children's hospital. Even the surgical instruments of a children's hospital are distinctive, witness the special characteristics of the outfit for intravenous injections. There are also special requirements for the feeding and washing of children, all much different from the corresponding requirements for adults.

Conditions in Lapland.—In 1956 a series of field studies of intestinal infections in a part of Finnish Lapland with a population of about 5,500 was made. Aided by the Department of Epidemiology of the Harvard School of Public Health, this team issued a report (*Nordisk medicin,* Jan. 22, 1959) which gives an illuminating picture of social conditions peculiar to this part of Finland. The ravages of World War II were so great that practically all the houses in the area in question were new. These houses, built since 1944, provide an anteroom or even two such rooms in succession so as to keep the main living room comparatively warm. A living room opening directly onto the outer world is now rare. Owing to great distances from school, many children have to live in boarding houses during the school term. Milk is not pasteurized and it passes from the producer direct to the consumer in most cases. When there is an intermediate agent, care is taken to keep the various supplies separate to avoid wholesale mixing. The slaughtering of reindeer is limited to the winter when the meat is kept frozen by natural means. Meat required for consumption in the summer is lightly salted and then smoked and dried in the winter. Here, again, the middleman is usually avoided, the householder either producing his own meat or getting it from his neighbor. Fresh meat is not eaten in the summer when fish becomes the householder's staple diet, much enriched toward the end of the summer by fruit and vegetables. Thanks in large part to the customary weekly steam bath, the personal cleanliness of this community is noteworthy.

INDIA

Alcaligenes Faecalis.—Sarkar and Tribedi (*Indian Journal of Medical Sciences*, vol. 12, December, 1958) stated that Alcaligenes faecalis, although described as a normal inhabitant of the intestinal tract, has also been reported by many workers to be the cause of enteric-like fever, meningitis, cystitis, abscesses, appendicitis, arthritis, and other conditions. For this reason all the strains of A. faecalis isolated from pathological material (blood, urine, feces, pus, and spinal fluid) received from different wards were studied by the authors. The feces of normal healthy persons and the feces of patients convalescing from acute diarrhea, dysentery, cholera, and typhoid were also cultured. All the strains were grown in special mediums to distinguish soil-forms of this organism from the intestinal type. Swabs from hands of house staffs and nurses and from the skin of the antecubital fossae of patients with a blood culture positive for A. faecalis were also cultured. Animal pathogenicity tests were made by injecting guinea pigs, rabbits, and mice by different routes with this organism, with or without mucin.

Previous immunization had been accomplished in some cases. Antibody response in patients from whose blood the organism was isolated was also found, blood from normal persons being used as a control. Of 1,960 consecutive blood cultures in a period of three years, A. faecalis was isolated from 93 patients, in 71 of whom the symptoms resembled those of typhoid, and in 14, atypical typhoid with remittent or intermittent fever. Two patients had puerperal fever, two had high fever late in pregnancy, one had fever following abortion, and three had subacute bacterial endocarditis. A. faecalis was isolated from 58 urine samples showing albumin and pus. During the period of study three patients had meningitis, two had abscess, one had pericardial effusion, one had pleural effusion, and one had cervicitis, all yielding A. faecalis on culture. The agglutinin titer could be determined in 32 patients with enteric-like fever whose blood cultures were positive for A. faecalis. Results of the Widal tests were negative in 9; the titer varied from 1:50 to 1:1,250 in 10; and in 13 it was below 1:50. The culture of swabs from the hands of nurses and house staff was uniformly negative, as were the cultures from the skin of antecubital fossae.

A. faecalis was isolated from 2 of 60 stools from healthy persons, 6 of 30 stools from patients convalescing from typhoid, 4 of 12 convalescing from dysentery, and 30 of 120 convalescing from cholera. By growing the strains in the synthetic mediums most of them could be identified as of fecal rather than soil origin. Animal pathogenicity tests showed the organism to be definitely pathogenic in mice when injected with mucin. When injected in an isolated intestinal loop of a rabbit, many strains were revealed to be pathogenic. In none of the patients in this series could a second organism be isolated from any pathological material. Immunizing injections produced protective antibodies in mice, supporting the pathogenic nature of this organism. All the strains, however, are not pathogenic and the virulence is not high. A high agglutinin titer is not a prominent feature of this infection, although 23 of the 32 patients so tested showed an antibody response. The organism could be isolated from the stools of only 2 of the 60 normal subjects, thus throwing doubt on its status as a normal intestinal inhabitant. Its incidence was, however, found to increase in intestinal disorders such as dysentery, acute diarrhea, and cholera. Most of the reported infections with A. faecalis have been from the tropics and subtropics. The authors believe that it probably plays a pathogenic role in these places and, when isolated from pathological material, should be considered as such and not just dismissed as a contaminant.

Gastroenteritis in Children.—Manchanda and Arora (*Indian Journal of Paediatrics*, vol. 25, November, 1958) analyzed a series of 665 cases of acute diarrhea in young children with regard to cause. Of 4,438 patients admitted during the two and one-half year period of study 665 (15%) had acute diarrhea. Of these 77.4% were in the first year of life. In this series 109 (16.4%) died, of whom 79 (15.3%) were below the age of 1 year. More than half the cases developed in the summer months. The mortality among bottle-fed infants was 21.3% compared to 9.18% among breast-fed babies; 424 patients came from poorer families with unsatisfactory housing conditions. Evidence of infection was present at the time of admission in 140 patients—66 had tonsillitis and pharyngitis, 30 had acute upper respiratory infections, 15 had a discharging ear, 14 had bronchopneumonia, 8 had multiple boils, and 7 had blepharitis. A history of previous attacks of gastroenteritis was obtained in 109, and a history of acute episodes of diarrhea in other siblings in the family was obtained in 72 cases. Stools were examined bacteriologically in only 50 cases. Serologic types of Escherichia coli 055 and 0111 were present in 30% of the specimens. A total of 84 strains were isolated from the stool specimens studied. Besides Esch. coli, other bacteria isolated were Paracolobactrum coliforme, 31.6%; Staphylococcus pyogenes var. aureus, 21.6%; Pseudomonas aeruginosa, 13.3%; and Shigella flexneri, 1.2%. In most stools more than one organism was isolated, pure growth of a single organism being found only rarely.

The incidence of toxemia, severity of the disease, and mortality rates were higher in patients excreting Proteus vulgaris, Ps. aeruginosa, and Staph. pyogenes var. aureus. Thus the mortality from Ps. aeruginosa infection was 66.7%; that from P. vulgaris infection was 37.5%; and that from Staph. pyogenes var. aureus infection was 26%. Esch. coli 0111 was found in three patients under the age of three months (one died), in two between the ages of three and six months, and in one over six months. Esch. coli 055 was isolated in six patients under the age of three months (one died) and in five between three and six months (one died).

All 665 patients were admitted as emergencies, having proved refractory to treatment outside; 384 had vomiting, 93 had blood and mucus in the stools, and dehydration of varying degrees was present in 505. Fluids were given intravenously to 490 and subcutaneously aided by hyaluronidase in 15. These fluids included dextrose solution, plasma, and whole blood. Saline solution was given if vomiting was excessive. Potassium chloride or citrate was added when dehydration was sufficiently overcome and the child started passing urine. Some patients also received calcium gluconate and multivitamin preparations parenterally. Various drugs such as sulfaguanidine, sulfasuccidine, streptomycin, chloramphenicol, chlortetracycline, and various combinations of antibiotics were given.

Blood Histamine in Adults.—Basu and Bhattacharya (*Indian Journal of Medical Sciences*, vol. 12, December, 1958) stated that in certain diseases, histamine is believed to be endogenously liberated, leading to variations in the blood level. It is therefore necessary to know the normal range of blood histamine before such pathological conditions can be distinguished from the normal variations. The authors estimated the blood histamine level of 25 healthy adults, excluding anyone with a history of cutaneous, nasal, or respiratory allergy. Estimations of hemoglobin concentration, total erythrocytes, and total leukocytes, and the absolute eosinophil count were also made. The normal range of blood histamine was found to vary from 1.0 to 6.2 mcg. per 100 ml. of whole blood, with a mean value of 3.8. The absolute eosinophil count ranged from 50 to 450 per cubic millimeter. There was no correlation between the blood histamine level and the absolute eosinophil count. These figures resembled those obtained by workers in other countries, although the highest range observed here is a little lower than that obtained by others.

Expansion of Health Services.—An indication of the standard of national health before India achieved independence could be estimated from the life expectancy of men and women, which was 26.9 years and 26.6 years, respectively, for the decade ending in 1930 and 32.5 and 31.7 years for the decade ending in 1950. Lack of medical facilities, technical personnel, and water supply were among the factors that contributed to this state of affairs. Inadequate financial resources further aggravated the situation. The first Five Year Plan allotted priorities to rebuilding the nation's health and laid the foundation for further progress. The Second Plan envisages bringing health services within the reach of all people. The specific objectives under the Second Plan are establishment of institutional facilities to serve as bases from which health services can be extended, training of technical manpower, control of communicable diseases, campaign for environmental sanitation, and family planning.

Surgical Treatment of Tuberculosis.—Padhi and Lynn (*Indian Journal of Tuberculosis*, vol. 6, December, 1958) reported that such procedures as phrenic paralysis, pneumothorax, and pneumoperitoneum have fallen into disuse in the treatment of pulmonary tuberculosis, their place now being taken by resection. Not a single pneumothorax or pneumoperitoneum was induced in their hospital in the last three years. In the authors' series of 150 pulmonary resections the indications were absolute in 118 and relative in 32; 41 had residual cavities, 38 had residual caseonodular lesions, 36 had destroyed lobes, 24 had destroyed lungs, 8 had tuberculoma or inspissated cavities, and 3 had bronchopleural fistula. Of those with residual caseonodular lesions 32 were subjected to resection as a prophylactic measure against reactivation, as they lived far away from the sanatorium and were likely to be lost to follow-up examinations over long periods. Advanced age was not considered a contraindication if the cardiorespiratory reserve was satisfactory. Thus, 15 patients in this series were 50 to 59 years of age and two were over 60; 16 had extremely poor pulmonary function. They were persistently positive, drug-resistant, and had undergone prolonged sanatorium treatment. The morbidity and mortality in these resections was high, but the risk of operation was preferable to a long downhill course. Of these 16 patients 3 died, but 13 were rehabilitated. Most of the 150 patients were between 20 and 30 years of age. All had had initial sanatorium treatment with chemotherapy which varied from three months to several years. On admission 139 had positive sputum; 46 had positive sputum and were drug-resistant at the time of resection. Bronchoscopy was performed routinely prior to operation to exclude endobronchial disease; bronchography was done in most of these cases. Deep breathing exercises and diaphragm control were started one week before operation and continued postoperatively.

SWEDEN

Treatment of Psychiatric Patients with Iproniazid.—Norring and Gottfries (*Svenska Läkartidningen*, Jan. 9, 1959) treated 100 patients at the psychiatric department of a general hospital in Malmö with iproniazid. The main indications for this treatment were depressive and asthenic states and the initial dosage was 25 mg. three times a day for a week, after which it was sometimes cautiously raised. The maximum reached was 150 mg. daily. The duration of treatment was up to seven months. In many patients the results were surprisingly good, but there were also many undesirable side-effects leading to withdrawal of the drug within a fortnight in 6 patients and after a longer interval in 17. In 58 patients hypotonic disturbances manifested themselves in giddiness, faintness, tinnitus, and "blackness of vision." Those with already existing hypotonia were much embarrassed by these hypotonic disturbances. Other side-effects were profuse sweating, headache, edema, and stranguria which in two of eight patients required catheterization that had to be continued two days after the drug had been withdrawn. There were also mental disturbances such as hypomania, which was observed in five patients.

Many of the 100 patients had been refractory to other methods of treatment such as electroshock, insulin, and sedatives, so the numerous successes achieved by iproniazid were the more impressive and an incentive to further trial under the closest control of the blood pressure, urine, and body weight. Hypertonic patients and others with a history of liver or kidney disease needed specially close watching. Epilepsy should be regarded as a contraindication for this treatment. The drug gave disappointing results in patients with presenile depressive states.

Cholesterol Metabolism.—Dr. H. Malmros of the University Hospital at Lund (*Nordisk medicin*, Jan. 2, 1959) reported on experiments carried out at his hospital by Dr. G. Wigand who fed rabbits a semisynthetic diet of pellets containing sugar, starch, casein, vitamins, 8% coconut fat, and salts, but no cholesterol. In spite of the total lack of cholesterol in this diet, the rabbits developed marked hypercholesteremia after a few weeks. On the completion of these tests after 110 days, atheromatous changes were plainly demonstrable in the aorta. On the other hand, rabbits fed on corn oil presented normal blood vessels. A series of 30 patients suffering from essential, familial hypercholesteremia were treated during the past two or three years by Malmros as follows: Animal fats in the form of butter, cream, milk, cheese, eggs, and meat fats and such other fats as margarine and cocoa fat were excluded from the diet, and dried milk and cheese from which milk fats had been abstracted and corn oil were substituted. This oil was used for salad dressing, mixed with porridge and mashed potatoes, and used for frying. Vegetables, fruit, sugar, and cereals were permitted, but bread made of wheat and cakes made with butter were omitted. Later fish, even fat fish, was added. Most of the 30 have been on this diet for over a year and they have on the whole tolerated it well. This diet was regularly followed in a couple of weeks by a fall in the serum cholesterol level. In some subjects there was a further fall, and in others the cholesterol maintained a steady level. Further investigations should show whether it is possible by using an appropriate diet to control arteriosclerosis.

When to Prevent Tetanus.—*Svenska Läkartidningen* for Jan. 16 again published (without giving the names of the offenders) cases brought to the attention of the Swedish Doctors' Disciplinary Committee. This time the hardy perennial question was raised: When should a wound be treated to prevent tetanus? A man, aged 63, injured his left index finger in a carding machine on Nov. 10, 1956. The terminal phalanx was amputated at a surgical polyclinic where bruised tissues were removed and the wound dressed. No prophylactic injection of tetanus serum was given but he was given penicillin at that time and again on his return to the clinic on Nov. 12 and 14. On Nov. 21 he returned complaining of severe pain in the finger and some necrotic tissue was removed. On the next day he complained of pain and stiffness in the nape of his neck and jaws. Tetanus being suspected, he was admitted to hospital whence he was discharged on Dec. 10 after having undergone a relatively mild attack of tetanus. While refusing to censure the doctors concerned, the committee took the occasion to quote the opinion voiced by the Swedish Surgical Society in 1951 to the effect that antitetanic serum should not be given merely for safety's sake but solely for real indications. The fact remains that 30 or more cases of tetanus continue to occur every year in Sweden, and the committee quoted the opinion of one of its experts that it would be well for the nation as a whole to be given the triple vaccine (whooping cough, diphtheria, and tetanus) soon after birth.

PHYSICAL FITNESS OF YOUTH

To the Editor:—The paper by Lane on "The Role of the Pediatrician in Physical Fitness of Youth" in The Journal (169:421-427 [Jan. 31] 1959) should not remain unchallenged. The American Medical Association has repeatedly called the attention of its members to the fallacy of accepting the norms for physical fitness on the basis of pure muscle strength. It is the well-recognized duty of every physician who treats children to strive for maximum achievement in all spheres of the young patient's development, and the pediatrician today is making a conscientious effort to guide parents toward that goal. He is appreciative of the fact that not all people are born to be athletes or weight lifters. The pediatrician takes more pride in a cardiac child, who as a youth can consider himself physically fit to be gainfully employed, than in a youngster who achieves stature as the captain of a football team.

"As we look about us today," the author states, "mindful of how seriously we took our responsibilities, many of us find cause for more amazement than pride in some of the children we remember as our healthy infant patients. Too often we see deterioration instead of development; young bodies, once firm and flexible, beginning to go slack and soft. We hear about too many backaches and we are appalled." What does the author mean by deterioration? If the implication is "slack and soft," how tight and hard should a muscle be before it is judged physically fit—and fit for what? Also, I am not aware of the great prevalence of backache as a disease of youth, and I have found quite a number of pediatricians who share this opinion. Not a single one seemed appalled by its incidence.

Is a youth to be considered physically unfit if he is too light for a football club or too short for a basketball team? It is the rehabilitationists who have taught us most about the importance of muscle function rather than mass as a criterion for fitness. One of the best pediatric residents we have had recently was a paralytic. He jumped around on crutches, always ready to learn and to serve. The patients loved him, so did the staff. I considered him physically fit, as did everyone who knew him.

At its annual meeting in 1957 the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association passed a resolution, part of which follows: "The Joint Committee . . . wishes to reiterate its belief that fitness is not a narrow or limited concept relating, for example, only to physical development, nor is it testable only by muscular strength, agility, or flexibility tests. On the contrary, fitness can be judged only through the use of a battery of evaluative procedures including appraisal of all aspects of organic, psychological, and social growth."

RADIATION THERAPY AND LEUKEMIA

To the Editor:—The diagnostic problem in The Journal (169:136-142 [Jan. 10] 1959) is an excellent presentation, and the conclusion reached by the authors seems reasonable and correct. The data from which these conclusions are reached, however, are inadequate—particularly the statement that the development of leukemia was the result of radiation therapy, which in one place was said to be intensive and in another place was simply mentioned as having been given. If radiation therapy is to blame for the development of this leukemia, it would seem logical that data be presented concerning the amounts of radiation given, areas treated, duration of time during which these treatments were administered, physical factors of the equipment used, and other necessary information so that one might arrive at a valid conclusion that excessive radiation therapy did lead to the end-result. Such loose reporting as appears in this article has been common in the literature in the past few years and has done more to harm the practice of radiology than has any other factor in the past few decades.

Eugene G. Tainter, M.D.
2909 J St.
Sacramento 16, Calif.

The above comment was referred to the authors of the diagnostic problem, and they have submitted the following reply.

To the Editor:—In view of Dr. Tainter's perfectly justified criticism we would like to submit the following addendum to the diagnostic problem "Erythremia (Polycythemia Vera), Radiation Therapy, and Leukemia."

The x-ray therapy given the patient, at another institution, is detailed as follows: From Sept. 9 to Oct. 10, 1952, a field 100 centimeters square was used to treat the spleen. A total of 750 r (air) was given in nine divided doses, eight from an anterior port and one from a posterior port. From Oct. 23 to

Nov. 6, 1952, an anterior port was used to treat the tibia and fibula, bilateral, entire length, giving 50 r (air) six times, making a total of 300 r (air). An anterior port was used to treat the femora, bilateral, entire length, giving 50 r (air) six times, making a total of 300 r (air). An anterior port was used to treat the upper extremities, giving 50 r (air) six times, making a total of 300 r (air). Factors in treatment of the spleen and extremities are 200 kv., 50-cm. distance from skin to focus, and half value layer of 0.95 mm. of copper. Triethylene melamine therapy was given from May 29, 1953, to Dec. 20, 1956, intermittently in small doses in courses varying from 1 to 13 weeks, in a total dosage of 260 mg.

Chicago 12.

FREEDOM FOR THE PROFESSION

To the Editor:—William S. McCann states in his letter to the editor in The Journal (169:410 [Jan. 24] 1959) that the changes in the treatment of physicians in the German democratic republic are due to "the strength of a strong professional organization." The fact is that no professional organization of any kind exists here and the changes mentioned in the letter were effected after a study by the central committee of the United Socialistic Party (S. E. D.).

IATROGENIC

To the Editor:—The word iatrogenic was coined several years ago to denote any disease induced by medical treatment. The classic example is cardiac neurosis in a patient whose doctor is too fussy. As such, iatrogenic is probably a useful word, but it is beginning to suffer from misapplication. A good example is the title "Iatrogenic Stiff Shoulders," appearing in the Feb. 28 issue of The Journal, page 945. These stiff shoulders are not produced by the physician, they are produced by the injury and the lack of exercise afterward. To call such a shoulder iatrogenic is akin to calling an embolic death iatrogenic because the doctor did not tie the femoral vein! There might be other factors, too. I think that we should bury the word iatrogenic.

XI. Conclusions 1797

I. The Controversy Over Krebiozen

During the past seven years the owners and proponents of Krebiozen, a substance alleged to be beneficial in the treatment of cancer, have been engaged in a great campaign to publicize this substance. They have been disseminating propaganda through articles strategically placed in newspapers, magazines, and books, as well as by organized letter writing, and they have been using national political channels to further their interests. They have already been involved in legislative investigations in two states, California and Illinois.

According to Herbert Bailey's book, "A Matter of Life or Death" (New York, G. P. Putnam's Sons, 1958), these individuals have made it clear that they wish to recoup from the sale of the substance an investment claimed to be about 2 million dollars and that they intend to sell the substance for profit as a proprietary drug. Despite this fact they have repeatedly petitioned health organizations supported by public funds to underwrite a test of the therapeutic efficacy of Krebiozen in collaboration with them. They have hoped to use public funds to defray the cost, estimated at $500,000 or more, of testing this privately owned substance.

Moreover, the chemical composition of Krebiozen remains unknown. The recent claims of its therapeutic efficacy which they have broadcast are based on case histories of patients treated with Krebiozen, although they have not given independent investigators access to these records within the last five years. The owners and proponents have demanded that the substance be tested according to their own terms, which are demonstrably unscientific.

Their steady campaign of publicity ostensibly designed to obtain support from either the American Cancer Society or the National Cancer Institute for testing the substance on their own terms has

---

News release of the American Cancer Society dated March 9, 1959.

aroused public interest in Krebiozen. The following documentation which chronicles the history of Krebiozen will provide answers to some of the questions which the public has been asking about this unproved substance.

II. What Is Krebiozen?

Krebiozen is a coined name applied to an alleged anticancer drug. It is said to have been produced by Dr. Stevan Durovic in Argentina prior to 1949. Dr. Durovic claims that he injected 2,000 Argentinian horses with Actinomyces bovis, a microorganism which causes "lumpy jaw" in cattle, and from the blood of these infected horses he extracted 2 Gm.—about one-half teaspoonful—of a whitish powder which he named Krebiozen. The full details of the method of extraction have never been revealed. Later, Dr. Durovic brought this powder to the United States. Here, without prior chemical analysis of the powder, he dissolved it in no. 9 mineral oil in the ratio of one part of Krebiozen to 100,000 parts of mineral oil. Thus he made the original (and only) supply of Krebiozen amounting to 200,000 doses, 1 cc. each.

III. The Men Behind Krebiozen

*Dr. Stevan Durovic**.—Born in Ulcinj, Yugoslavia, in 1905, Dr. Durovic received the degree of Doctor of Medicine from the University of Belgrade in 1930. He did postgraduate work at the University of Vienna and at the Pasteur Institute in Paris. During World War II, as a captain in the Medical Corps of the Royal Yugoslav Army, he was taken prisoner by the Italian army and was held for 18 months. In 1942, on the basis of his being a physician in ill health, he was released and he traveled to Spain and Argentina on a Yugoslav passport with a Vatican visa. In 1944 in Buenos Aires, he established Duga, S. A., which was financed by his brother Marko Durovic, a former munitions manufacturer. At the Duga laboratories he prepared a "whitish powder" which he named Kositerin and which he thought was useful for treating high blood pressure. Dr. Durovic visited the United States in March, 1949, for the purpose of working with doctors at Northwestern University in testing Kositerin. Kositerin was found to be without value for the treatment of high blood pressure.

In August, 1949, Dr. Durovic met Dr. Andrew C. Ivy, a distinguished medical researcher and vice-president of the University of Illinois. At this time Dr. Durovic told Dr. Ivy about another substance, Krebiozen, which he believed was effective against cancer, and he solicited Dr. Ivy's help in testing the drug.

Dr. Durovic is not licensed to practice medicine in this country. He has stated that he is interested only in research, but he has not published in any scientific or medical journal in this country during his nearly 10 years of residence here. In July, 1952, he was granted permanent residence in the United States through Senate Bill 1159, sponsored by Senator Paul Douglas of Illinois. In September, 1958, he became a naturalized citizen of the United States.

Dr. Andrew C. Ivy.—Born in Farmington, Mo., in 1893, Dr. Ivy received his Ph.D. from the University of Chicago and his M.D. from Rush Medical College. He has been the author or co-author of many published scientific articles. Numerous honorary degrees have been awarded to him, and he has held important posts in several universities, in the government, and in private organizations. He was at one time scientific director of the Naval Medical Research Institute, executive director of the National Advisory Cancer Council, and consultant (on war crimes) to the Secretary of War. When he met Dr. Durovic in 1949, he was vice-president-in-charge of the Chicago Professional Colleges of the University of Illinois and distinguished professor of physiology and head of the department of clinical science at the university.

Although he had not previously published any papers on Krebiozen in medical journals, at a meeting in the Drake Hotel in Chicago on March 26, 1951, attended by physicians and laymen including members of the press, Dr. Ivy submitted a privately printed, 106-page brochure which favored Krebiozen and of which he was co-author. The meeting was widely publicized in newspapers and there was a public furor over Krebiozen. Because of the methods Dr. Ivy had used to promote Krebiozen, his membership in the Chicago Medical Society was suspended for three months. Although he was later invited to reinstate his membership, he declined to do so and was dropped from the roster of the society for nonpayment of dues. This action automatically terminated his membership in the Illinois Medical Society and the American Medical Association.

Dr. Ivy has stated that the process of manufacturing Krebiozen has not been revealed to him and that he has neither seen nor analyzed the original substance in the undissolved state. He has also stated that in Chicago he has extracted a substance from 40 horses, recreating by deduction the process that Dr. Durovic used to extract Krebiozen in Argentina. Dr. Ivy is reported to have obtained 10 times the amount of powder that Dr. Durovic claimed to get from the same number of animals. However, since the composition of Dr. Durovic's powder has never been revealed, there is no way of knowing whether the substance extracted by Dr. Ivy in the United States in 1957 is the same as that obtained by Dr. Durovic in Argentina eight years before.

---

*Details of Stevan Durovic's career before he came to the United States are based on a pamphlet published in June, 1953, by the Krebiozen Research Foundation, and on a letter, now in the files of the National Cancer Institute, from the foundation's secretary.

Several other physicians in association with Dr. Ivy have privately published monographs on Krebiozen. These men are Dr. J. F. Pick, a plastic surgeon; Dr. W. F. Phillips, a general practitioner; and Dr. L. Krasno, a researcher in antibiotic dusts.

*Marko Durovic**.—Born in Ulcinj, Yugoslavia, in 1900, Marko Durovic, brother of Stevan Durovic, received his legal training at the University of Paris and the University of Belgrade, completing his training in 1923. In 1926 he was appointed judge in the Yugoslav District Court in Belgrade. He practiced law from 1927 to 1941 and was co-owner of Vistad, a munitions plant. In 1942 he was seized by Italian troops and was sent to Rome. Through the intercession of the Vatican he was released and allowed to travel to neutral Argentina with his brother. There he bought a steel plant and the Instituto Biologica Duga and underwrote his brother's experiments which produced "Kositerin." He came to the United States in 1950 on a visitor's visa. In July, 1952, he was granted permanent residence in the United States through Senate Bill 1159, sponsored by Senator Paul Douglas of Illinois. In September, 1958, he became a naturalized U. S. citizen.

IV. Organizations Connected with Krebiozen

A number of organizations have been created by the supporters of Krebiozen to publicize, promote, and distribute the drug and/or to obtain public support for the testing of Krebiozen according to the terms laid down by its proponents. These organizations are:

1. Duga Laboratories, Inc., Chicago, and Buenos Aires, Argentina. This drug firm was established by Marko Durovic to underwrite Dr. Stevan Durovic's experiments which produced Krebiozen. Duga Laboratories, Inc., distributes Krebiozen to physicians through the Krebiozen Research Foundation (see below), which it supports. Duga Laboratories, Inc., accepts from the foundation moneys which the foundation receives as contributions from patients who have been given Krebiozen. According to Herbert Bailey's "A Matter of Life or Death," Dr. Durovic has stated that the Duga Laboratories, Inc., is in debt to creditors who expect to receive a return on their investments if Krebiozen is proved to be an effective cancer remedy.

2. The Krebiozen Research Foundation, Chicago. This foundation is registered in the state of Illinois as a nonprofit corporation. It furnishes Krebiozen to selected physicians for use in treating patients. The necessary steps under the Public Health Service Act have never been taken to make it possible for Krebiozen to be sold for use in interstate commerce (see section VII). However, the recipient is requested to make contributions to the Duga Laboratories, which supports the foundation. The request for contributions is at the rate of $9.50 per ampul. The Foundation Library Center reports that as of February, 1959, the Krebiozen Research Foundation had not published a list of officers, a report of activities, or a financial statement.

3. Committee for Independent Cancer Research, Inc. Originally formed ostensibly to investigate various cancer remedies, this organization has put forth major efforts to promote Krebiozen and a book "Krebiozen, Key to Cancer?" written by Herbert Bailey, president of the committee. Because of a disagreement over a matter of policy, this committee has since split into two divergent groups: (*a*) The Freedom for Cancer Research Committee. Mr. David M. Kasson, who claimed he had been treated for cancer with Krebiozen, presided over this committee. Upon his death from cancer in June, 1958, the committee was dissolved. (*b*) The Independent Cancer Research Foundation, Inc. Miss Gloria Swanson, former chairman of the Committee for Independent Cancer Research, serves as a member of the board of directors. This group is devoted to gathering and disseminating "all possible information on trends in cancer research and treatments."

4. Committee for a Fair Test of Krebiozen, Inc. This group has circulated petitions urging the American Cancer Society to support the method of testing of Krebiozen which its proponents are demanding.

5. The Lakeland Foundation of Chicago. This organization has also been involved in the Krebiozen controversy. According to the Foundation Library Center it is a private corporation and is incorporated under a broad charter that includes conservation of natural resources, care of the aged, research in economic science, and medical research in the field of malignancy. The Lakeland Foundation does not currently publish an annual report.

The Lakeland Foundation has come to Dr. Ivy's assistance on two occasions. When he was on a leave of absence from Jan. 1 through June 30, 1953, from the University of Illinois and without salary, the foundation loaned him $5,000 for living expenses. In 1956-1957, the Lakeland Foundation advanced the sum of $10,000 to Dr. Ivy for the purpose of recreating Krebiozen.

V. Has Krebiozen Ever Been Tested?

1. (*a*) The powder form of Krebiozen was never chemically analyzed before being dissolved in mineral oil. An analysis of Krebiozen dissolved in no. 9 mineral oil has been done by the Clark Microanalytical Laboratory, Urbana, Ill., and was reported in *Chemical Week*, June 16, 1956. According to the Clark analysis, "It contained no nitrogen and . . . might contain some sulphur in addition to carbon, hydrogen and oxygen. Infra-red and ultraviolet

---

*Details of Marko Durovic's career before he came to the United States are based on a pamphlet published in June, 1953, by the Krebiozen Research Foundation, and on a letter, now in the files of the National Cancer Institute, from the foundation's secretary.

spectroscopy revealed absorption bands indicating that it could be either a polysaccharide or a steroid. A further study of the product is required before a more definitive statement about its chemical structure can be made."

(*b*) Two distinguished chemists, Drs. Paul Kirk of the University of California and Arthur Furst of Stanford University, testified at the 1958 hearings of the California General Assembly Committee on Public Health that they had independently attempted to extract and to analyze Krebiozen. After the most exhaustive tests Dr. Kirk independently concluded that "the extraction failed to reveal the presence of anything dissolved in the ampules and would lead to the supposition that all that is contained in Krebiozen is mineral oil, Nujol, to be specific, because the analysis indicated the identity with Nujol." Dr. Furst concurred. "I say it is pure Nujol," he stated.

Dr. Ivy has challenged this testimony.

2. (*a*) A few animal studies have been done with Krebiozen by its proponents. From these studies it is claimed that the substance is nontoxic in rats, cats, and dogs.

(*b*) Twelve dogs were said to have been treated with Krebiozen by Dr. Hannibal DeGrana at the School of Veterinary Medicine of the University of Buenos Aires. All the animals were described as having natural cancer; seven animals were said to be almost blind because of cataracts. It was said that all of the tumors were affected to some degree and that in six dogs the cataracts cleared and the dogs regained sight.

(*c*) John B. Loefer, Ph.D., of the Southwest Foundation for Research and Education, San Antonio, Texas, reported on the effects of Krebiozen therapy on transplanted mouse leukemia and lymphosarcoma in The Journal of the American Medical Association on May 17, 1952. "Krebiozen . . . did not affect the course of development of either the leukemia or the lymphosarcoma," he wrote.

3. (*a*) In 1952, the Committee on Research of the Council of Pharmacy and Chemistry of the American Medical Association published "A Status Report on Krebiozen" in The Journal of the American Medical Association. This report, made by a group of four distinguished educators from several medical schools in Chicago (excluding the University of Illinois), contained an analysis of 100 case histories of patients treated with Krebiozen. The case records had been received from seven sources and were examined at the request of Dr. Ivy and his associates at the Krebiozen Research Foundation.

"Ordinarily, the Committee on Research . . . would not attempt to evaluate the clinical benefits, if any, of a substance whose character and method of manufacture were not known and standardization of which was so loosely defined," the A. M. A. report stated. "However . . . tremendous worldwide public interest created a moral obligation . . . which transcended the issue of medical ethics ordinarily applicable to secret remedies."

The conclusions of this report were:

"Ninety-eight (of 100 cases studied) were reported as failing to show evidence of improvement.

"Two patients showed some evidence of temporary improvement coincident with Krebiozen therapy. In one patient this was apparently fortuitous; in the other major lesions showed continued rapid progression."

(*b*) Seven investigators reported on 63 cancer cases treated with Krebiozen to the Committee on Cancer Diagnosis and Therapy of the National Research Council. The committee then reviewed these and other cases in 1951 and found "no evidence of any curative effect and no proof of palliative effect attributable to the 'drug' itself." This opinion was based on an analysis of the 100 cases already reported in The Journal, some of which were included among the 63 cases studied by the Committee and the 22 cases reported by Dr. Ivy and others in the booklet distributed at the meeting in the Drake Hotel on March 26, 1951, when Krebiozen was first announced.

(*c*) In 1952, a committee of six distinguished physicians from several medical schools, headed by Dr. Warren H. Cole, head of the department of surgery of the University of Illinois, was appointed by Dr. George Stoddard, president of the university, for the purpose of reviewing Dr. Ivy's 500 cases of cancer treated with Kreboizen. The committee's report, presented to the trustees of the university, contained the following significant conclusions: "Ignorance of the material interferes with a sound evaluation of its therapeutic effectiveness . . . no acceptable evidence that any malignant tumor had been cured by Krebiozen . . . no evidence of prolongation of life . . . no histological evidence that Krebiozen produced degenerative or regressive changes in tumor cells . . . no radiographic evidence that Krebiozen could reduce metastatic tumor lesions in bones or lungs . . . statement in Dr. Ivy's report that a large majority of patients reported a decrease in pain was not confirmed."

In a discussion of future tests, the Cole committee advised that a supply of Krebiozen should be made available for testing and that investigators should attempt to reproduce the material and determine its chemical content.

(*e*) A committee of supervision, under the chairmanship of Dr. Robert E. Johnson, head of the department of physiology, Urbana, Ill., was appointed by Dr. Stoddard to carry out the recommendations of the Cole committee. The committee of supervision reported in part that "a supply of the original material was needed so that it could be tested directly. A supply of the vehicle was needed for adequate scientific control. Complete information on the mode or modes of preparation was needed

. . . the originators of the preparation are unwilling to furnish materials and will not provide full technical information . . . (therefore) the committee is unable to proceed further."

(*f*) In 1952, after a 21-month investigation, Dr. Stanley P. Reimann, director of the Institute for Cancer Research, Philadelphia, announced: "We now know we have cured no patients [with Krebiozen] and we don't believe the length of life has been prolonged on any we have treated."

4. The proponents of Krebiozen have been involved in legislative investigations in two states and have received support from at least two U. S. Senators and one U. S. Representative.

(*a*) The Illinois legislature: In 1953, a joint committee of 14 Illinois legislators was appointed from the two state legislative bodies to investigate the Krebiozen controversy. In 1954, after extensive hearings for which records were subpoenaed, this committee concluded that Dr. Ivy and the Durovic brothers "were men of good character" and that neither Dr. Stoddard nor the American Medical Association had conspired against Dr. Ivy. The committee urged further research on Krebiozen but made no recommendations as to how this research was to be conducted.

(*b*) The California Senate: In 1958, the California Senate Committee on Public Health held hearings on "Fraudulent, Dangerous, Unscientific and Deceptive Practices in the Field and Treatment of Disease" at which Dr. Ivy testified. The burden of Dr. Ivy's testimony was directed to the advocacy of a "double-blind" test of Krebiozen which its proponents have been endeavoring to get.

(*c*) The late Senator Charles W. Tobey: Senator Tobey is reported to have sponsored an investigation of Krebiozen by a staff investigator.

(*d*) The Honorable Roland V. Libonati, U. S. Representative from the State of Illinois: On several occasions, Congressman Libonati has had remarks on Krebiozen inserted in the Congressional Record. His remarks have generally echoed Dr. Ivy's.

(*e*) Senator Paul Douglas of Illinois: Senator Douglas sponsored a bill in the U. S. Senate which gave the Durovics permanent residence in the United States. On the floor of the United States Senate, in August, 1958, Senator Douglas proposed a "Fair Test of Krebiozen" to be done by the National Institutes of Health, a U. S. Government institution. Later, Drs. Ivy and Durovic met with Dr. Heller, director of the National Cancer Institute of the National Institutes of Health, and with a representative of Senator Douglas. At this meeting, Dr. Heller stated that "the first step should be an examination of the case records in possession of the Krebiozen Foundation."

At a meeting on Sept. 24, 1958, attended by Drs. Ivy and Durovic, Senator Douglas's representative, and Dr. Heller, it was generally agreed that the evaluation of Krebiozen should be explored further and that the group was seeking to develop an agreed procedure that would be acceptable to the scientific community.

On Dec. 5 at another meeting attended by the same group, this time including Senator Douglas, the National Cancer Institute suggested an examination of Dr. Ivy's data by a committee of mutually acceptable scientists to decide whether clinical trials should be undertaken and how they should be undertaken. Senator Douglas expressed the opinion that this suggestion was a proper one. Dr. Ivy was invited to define his role as consultant to the evaluating committee, to which he had agreed.

He answered in a letter to the Institute dated Feb. 1, 1959, insisting that he personally should be a member of "an arbitration type of committee" and "a party to the administration of the therapy and the interpretation of the results under conditions where bias cannot operate." This is a procedure which, as pointed out in two conferences attended by Dr. Ivy, could admit bias and would not be acceptable to the scientific community.

The Institute responded to Dr. Ivy's letter on Feb. 6 by asking him to clarify his apparent rejection of the previous plan made between him and the National Cancer Institute, because "it is the desire of the Institute to get on with the evaluation of Krebiozen as soon as a scientifically acceptable procedure can be effectuated."

VI. Can Krebiozen Be Tested?

The proponents of Krebiozen have frequently stated that they would welcome an evaluation of their preparation, and during the last two years they have conducted an active campaign to promote a specific type of evaluation which they have outlined as a "double-blind" test.

In the past, an evaluation of Krebiozen by independent researchers has been obstructed because of lack of information about the substance and its preparation and the unavailability of the substance. Thus, the Committee on Supervision, which was appointed at the University of Illinois in 1952, was unable to proceed with an evaluation of Krebiozen.

Also, independent evaluation of Krebiozen has been impeded because of inadequate information about the drug, the unwillingness of its proponents to surrender to independent researchers the case histories on which they base their claims, and the insistence of the proponents that Krebiozen be tested only on the terms which they themselves have set forth—terms which have been unacceptable to reputable scientists unassociated with Krebiozen.

Recently, the supporters of Krebiozen have concentrated their propaganda efforts on trying to get a reputable organization to sponsor a "double-blind" study of their substance.

The proposal for such a study was first made to the American Cancer Society in 1958 by James L. Griffin, Director of the Krebiozen Research Foundation.

Briefly, the study proposed by Mr. Griffin called for the appointment of a committee of laymen and a committee of physicians, one-half of the members of each committee to be selected by the Krebiozen proponents and one-half to be chosen by the American Cancer Society. Each committee would then select a single additional member. Ampuls of plain mineral oil and ampuls of Krebiozen identified only by code numbers would be administered by Dr. Ivy to known cancer patients. The extra member of the lay committee would be the only person to know the identity of the contents of the ampuls, and he would be instructed to keep the code list in a safety deposit box.

At the end of the period of treatment Dr. Ivy would evaluate the results and undertake to identify the patients who had received Krebiozen and those who had not. Committee members would be permitted to observe the patients and to take notes during the treatment period.

The Krebiozen proponents claim to have 1,200 case records of patients already treated with Krebiozen. In testing an unproved substance, the first step would be to evaluate the results already achieved, and in this case it would mean an analysis of the alleged case records. In its proposal to the American Cancer Society, the Krebiozen Research Foundation, however, refused to permit an examination of these case records, unless the Society agreed beforehand to sponsor their suggested study.

Their proposal for this particular study was carefully considered by the American Cancer Society's Advisory Committees on Research and on the Therapy of Cancer and by the Society's Research Advisory Council. These three groups of scientists concluded that this proposal "does not provide a scientifically valid plan for conducting an objective and meaningful evaluation." Their opinion was adopted by the Board of Directors of the American Cancer Society on Oct. 24, 1958.

The first reason for rejecting the proposal was that the committees to be set up as outlined by the Krebiozen proponents would not be truly independent research groups, because one-half of the membership of each committee would consist of individuals selected by the proponents.

The second reason was that the plan stipulated that only Dr. Ivy would administer the Krebiozen. The American Cancer Society felt that this would not permit "an opportunity to determine whether physicians generally can obtain the same results."

The third reason for rejecting the proposal was that the plan "provides no clear-cut standards for either measuring the result desired or defining or measuring the results obtained."

The Society further stated that it would be willing to support "the testing of any substance proposed for the prevention, treatment, or cure of cancer, provided the substance is available for testing under the well-established scientific methods known and accepted for all products proposed for human use, and further, provided that satisfactory preliminary evidence exists that the substance has shown promise of being useful in the treatment of cancer."

The American Cancer Society itself cannot test any drug. It does not operate research laboratories, nor does it control hospitals or other facilities for the treatment of cancer patients. The Society has clearly made it a matter of record that it favors the full knowledge and testing of Krebiozen.

VII. Is Krebiozen Patented? Can It Be Sold?

The owners of Krebiozen have stated on numerous occasions that they have a large investment in this substance and intend to market it for profit. For this reason they are concealing the details of the manufacturing process, thereby setting up a barrier to the testing of the substance by independent researchers.

If the owners of Krebiozen wish to protect the substance, they may apply for a patent on it. They may also apply for a patent on the process by which it is made. Hundreds of drugs are manufactured in this country under such patents.

Such applications are temporary protection for the proponents while the patents are being searched.

Some years ago the owners of Krebiozen applied for a patent but when the U. S. Patent Office returned the application with request for further information, the owners of Krebiozen failed to supply this information and did not resubmit their application. Hence, there is no patent or new application for a patent on Krebiozen, either the substance or the process, in the files of the U. S. Patent Office as of January, 1959.

By its description Krebiozen is subject to the biological control provisions of the Public Health Service Act and thus it may not be legally shipped for sale, barter, or exchange in interstate commerce or exported from or imported into the United States, unless it is produced under government license. No application for such license has ever been completed for Krebiozen. If an application were made, supported by adequate evidence of safety, purity, and potency of the product, it would be the responsibility of the Division of Biologic Standards of the National Institutes of Health to recommend whether or not a license should be issued. Without this license Krebiozen may be distributed only to qualified experts, solely for purposes of clinical investigation, but it cannot be sold. Some physicians, as indicated in section IV, have obtained Krebiozen in this way since 1952.

VIII. Publicity and Promotion of Krebiozen

The history of Krebiozen has presented elements both of wide publicity and of deep secrecy. Some of the proponents, although they are physicians and well acquainted with the accepted procedures for introducing a new substance, have ignored and flouted these procedures in the case of Krebiozen. From the very first they have sought to arouse the public interest in Krebiozen before adequately demonstrating to the medical profession the utility or efficacy of the substance.

For this unorthodox approach, Dr. Ivy was disciplined by the medical society of which he was a member. He consequently was relieved of his position as vice-president of the University of Illinois. Such censure, however, has not deterred him from continuing to publicize Krebiozen. He has since appeared on television and radio programs devoted to the promotion of the drug, has held interviews with the press, and has made other public appearances in behalf of Krebiozen.

An example of Dr. Ivy's methods of attracting publicity is provided by the circumstances of his recent letter to Dr. Harold S. Diehl, senior vice-president for research and medical affairs of the American Cancer Society, proposing a test of Krebiozen. Dr. Ivy was not content merely to communicate privately with Dr. Diehl. At the time he sent this letter, he also released copies of it to the press in an obvious effort to create publicity.

The press releases that have been issued by the proponents of Krebiozen, or in their behalf, are not always consistent with the facts. For instance, G. P. Putnam's Sons, publishers of the new book "A Matter of Life or Death, the Incredible Story of Krebiozen" by Herbert Bailey, issued a press release stating that "'the evaluation of Krebiozen—the controversial anticancer agent—by the National Cancer Institute is under way and will proceed with all possible speed,' Dr. John R. Heller, the Institute's Director told Herbert Bailey (sic)." This release, dated Nov. 11, 1958, also declared that the National Cancer Institute had agreed to conduct a "double-blind" test of Krebiozen. Herbert Bailey, who apparently prepared the Putnam release, had sent a copy of it, prior to its publication, to Dr. Heller for his suggestions. Dr. Heller answered immediately, on Nov. 6, 1958, correcting two inaccuracies in the copy: (1) the evaluation of Krebiozen is not under way, and (2) the method of testing has not yet been agreed upon and cannot be determined until examination of data has been completed. "Actually," wrote Dr. Heller, "we are now approaching the preliminary stage of examining the data submitted by Dr. Ivy to determine whether it warrants further investigation of the treatment."

Although Dr. Heller's comments were sent to Mr. Bailey five days before the press release was published, Mr. Bailey replied that they were received too late for the necessary revisions to be made.

It has also been pointed out by Dr. Heller that on Sept. 24, 1958, when he and other members of the National Cancer Institute met with Drs. Ivy and Durovic to discuss the testing of Krebiozen, Drs. Ivy and Durovic subscribed to a press release issued by the National Cancer Institute which stated that the method of testing Krebiozen should be acceptable to the scientific community. At that meeting, there was no agreement to undertake the "double-blind" study proposed by Dr. Ivy and which had already been widely rejected by scientific investigators.

IX. National Cancer Institute Requirements

The conditions under which the National Cancer Institute would consider an investigation of Krebiozen are based on principles long accepted by the scientific community at large. They apply to the testing of any drug, the value of which has not been adequately proved. These accepted conditions were first outlined by the National Advisory Cancer Council as guide lines for the National Cancer Institute in evaluating compounds and are subscribed to by the American Cancer Society. They are the following:

1. The chemical formula, if known, must be disclosed to the National Cancer Institute, or if not known, the method of preparation must be supplied.
2. Adequate amounts of the chemical having known purity must be available.
3. The evidence upon which any claim of efficacy is based must be presented along with a full explanation of the method of treatment.
4. The National Cancer Institute reserves the right to determine if, how, where, when, and by whom the investigation is to be carried out.
5. The scientists making the investigation will have the right to publish the results.

The National Cancer Institute is willing to undertake an evaluation of claimant's data on an unorthodox treatment claimed to effect cancer cures in humans, provided that the following conditions are accepted:

1. The method of treatment must be fully explained. There must be full disclosure to the National Cancer Institute of the composition or nature of the treatment.
2. Complete records of clinical and laboratory findings must be submitted of the total number of patients with cancer treated with the remedy or method in question. These records must demonstrate the following: (*a*) Diagnosis of cancer in each case, confirmed by verifiable microscopic examination. (*b*) Detailed and documented objective evidence that malignant neoplastic disease has disappeared or that its progress has been arrested for a significant period of time in a significant number of patients. It must be shown that no definitive treatment other than the one in question was used during this period of observation; in addition, a detailed record of all treatment received by the patients prior and subsequent to the test period must be supplied. (*c*) Details as to preparation, dosage, frequency, and route of administration of the agent in question. (*d*) Complete details as to physical and supportive laboratory findings and histological studies in the patients prior to, during,

and subsequent to the course of and cessation of the treatment in question. (c) Objective evidence of regressions of primary tumor and metastases as shown by recorded measurements of observable tumors, photographs, and x-rays, with dates of observation.

3. The National Cancer Institute reserves the right to determine whether or not the evidence submitted warrants further investigation of the proposed treatment and its results and reserves the right to determine where, when, by whom, and under what conditions such investigation will be made. The National Cancer Institute reserves the right to make public its findings.

X. The American Cancer Society and Unproved Drugs

Under the American Cancer Society's research program, hundreds of organic and inorganic compounds have been screened and a few substances have been found which are palliative in certain types of human cancer. The results of research on all of them were first published in medical journals. All of these substances can be manufactured by a drug concern and all are readily available to doctors and to hospitals for experimental purposes.

The American Cancer Society is dedicated to the task of finding the cause and the cure of human cancer at the earliest possible moment. To this end, it supports scientific investigation of every promising kind. At the same time, however, it has the responsibility of seeing to it that the public is not misled by enthusiastic claims of individuals who would exploit unproven methods or drugs for the treatment of cancer. Ill-advised reliance on such unproven methods or substances militates against possible cure of the disease by the acceptable methods known at the present.

Any drug which is claimed to cure cancer must fulfill certain objective criteria. Krebiozen has not met these standards. No acceptable evidence that treatment with Krebiozen causes any objective benefit in human cancer has yet been offered by independent researchers.

XI. Conclusions

Advocates of Krebiozen have demanded through all publicity channels what they describe as a "fair test" of the drug. The National Cancer Institute of the United States Public Health Service is willing to conduct a test to further evaluate Krebiozen but insists that it be done in a manner acceptable to the scientific community.

The Krebiozen Research Foundation, Dr. Ivy, Dr. Durovic, and their associates have long claimed they have a tool useful against cancer: it is, then, their clear duty to thousands of cancer patients to cooperate with the National Cancer Institute or any group of competent, objective scientists in an objective test of the drug. Delays now are clearly the responsibility of the Krebiozen Research Foundation.

When Krebiozen was first announced, it was tested in hospitals, clinics, and laboratories, according to scientifically accepted procedures. The results of the tests carried out by scientists and clinicians were reviewed in reports mentioned in section IV. This avenue of testing still remains open to advocates of Krebiozen.

However, the agitation continues. This has an unsettling effect on cancer patients, their families and friends, who question whether the extraordinary claims about Krebiozen are true. The answer can only be settled by a thoroughly objective study such as the one the National Cancer Institute has indicated it is willing to make.

The American Cancer Society hopes that the Krebiozen Research Foundation will recognize the integrity of the National Cancer Institute of the United States Public Health Service and respect its well-established methods and procedures and that the foundation will drop its demands for its own rules and procedures.

THE WORLD'S PLAYGROUND

Known for three generations as the world's playground, Atlantic City has the world's largest compact playground for children, seven miles of beach blocked off by a boardwalk on which no auto traffic is allowed. When physicians gather in Atlantic City, June 7-12, for the convention of the American Medical Association, many will bring their wives and children. The city has merry-go-rounds, Ferris wheels, auto whips, boat rides, caterpillar thrills, airplane rides, tilt-a-whirls, and other breath-taking amusements. Dotting the Boardwalk are Pennylands and Funlands where youngsters can find delights all day for nickels and dimes. They can play miniature baseball and basketball, ride "jet" airplanes and submarines, and hunt miniature moving bears and lions. They can try to ring a prize, test their bowling prowess, or push around golf balls on miniature courses decorated with Disney or Mother Goose characters.

Steel Pier is also a happy place for children. Appealing to adults as well are its famed diving horses, which leap from a 40-ft. platform into a tank with girl riders astride their bare backs, and its water circus with crazy clowns. Steel Pier also has a sea-zoo, a children's theater, a Ripley's Believe-It-or-Not exhibit, and a picnic deck.

In addition to the special programs provided by Atlantic City's hotels and motels, the resort also has in operation during the summer 21 children's playgrounds, as well as shuffleboard courts, bowling alleys, and roller skating rinks, which older children can enjoy. The Boardwalk also has dozens of stores specializing in novelties and toys. In June, when the physicians will be here for the big A. M. A. powwow, manufacturers and distributors will be stocking these stores with new toys.

THE LEISURE CORNER

FLYING PHYSICIANS

Man's desire to achieve flight has been evident from early times. Myths and legends of many peoples relate adventures in flying, one of the most familiar being the Greek myth of Daedalus and Icarus. In the 13th century Roger Bacon proposed the construction of a flying machine with wings that could be operated by the person being carried. The detailed observations, explanations, and drawings found in the notebooks of Leonardo da Vinci mark the beginning of scientific studies of flight. Flight was first successfully accomplished in 1783 in a lighter-than-air device today known as a balloon.

At the beginning of the present century aviation was still in its infancy. Only a handful of men were interested even in gliding. When the Wright brothers made their first flight in a powered, heavier-than-air craft in 1903, they stayed in the air only a few seconds. Today the airplane has created a vast and growing industry, revolutionizing travel and warfare and bringing about tremendous changes in commerce, science, international politics, and the world's standard of living.

Insofar as flying pertains to the practice of medicine, stories about mercy flights to save lives have become commonplace in newspaper accounts. Physicians and nurses have been flown into areas cut off by floods, fires, and other disasters. Sick and injured people have been flown from their homes to hospitals hundreds of miles away in a short time. Moreover, airplanes and helicopters have been equipped as flying ambulances and are used to hunt for and rescue persons lost in forests, at sea, or on mountains. Special drugs, medicines, and isotopes are transported quickly in emergency situations, whereas without the airplane the matter would be time-consuming.

As a hobby for doctors, an excellent way to get off crowded highways and enjoy the wondrous beauties of the wide blue yonder is to own and fly a private airplane. There is much difference between piloting a small private airplane and traveling on a large commercial aircraft. An individual flying on his own must learn the art, get accustomed to the air, and depend on his own skill and judgment. The attributes of skill and judgment should not be alien to a physician, since he is always confronted by situations requiring their application in daily medical practice.

Many persons find they can solo after about eight hours of dual instruction. Experience accumulated during a period of preliminary flight training usually will influence one either to continue with enthusiasm or to drop completely the idea of pursuing further the hobby of flying. One of the most frequent causes for giving up flying a small airplane is the fear of becoming lost, especially during heavy fog. Although the experience of being lost is sometimes terrifying, most flyers regain their confidence quickly.

The student pilot immediately becomes aware that it is not the engine alone but the entire shape and construction of the airplane that cause it to fly. To illustrate, gliders fly without the aid of engines. The beginner must therefore learn something about the nature of air—that it will hold him up just as water holds a swimmer up when he acquires confidence and learns to handle himself properly. Too many people think of a small airplane in terms of an automobile or a motor boat, to be steered around all the curves. The truth is that an airplane is more like a bicycle, which has to be balanced around curves.

You will find that when you pilot your own airplane you will see much more than when you were a passenger on a huge commercial airliner. The need for seeing is important; the pilot needs to see where he is going. In addition, say the owners of private airplanes, the ability to see the surroundings is the very heart of the pleasure to be derived from piloting a private airplane.

Ordinarily, it is not advisable to buy an airplane at the first flush of one's original enthusiasm for flying. The situation is not comparable to buying an automobile in order to learn how to drive it. It is best to learn the art of flying at a reliable flying school. Then, when this is accomplished satisfactorily, the next step is to rent an airplane; under these circumstances, the owner of the airplane will be justifiably concerned for the safety of the pilot. Eventually the pilot will be able to evaluate the characteristics of small airplanes and will be ready to consider purchasing his own.

After a sufficient period of practice in the air the new pilot realizes that he is obtaining an entirely fresh view of the countryside, together with a thrilling, exuberant feeling of well-being and personal satisfaction. Many private pilots take trips to North Dakota. When asked why, they answer: "The landings are unlimited, as far as the eye can see; the fields are big and flat as a table, much larger than airports." When planning a vacation in a private airplane, there arises always the possibility of viewing new vistas and aspects of the United States hitherto unseen and unvisited. Everything the flying physician will want to see is within easy flying distance, no matter what the point of origin. California can be reached from Chicago in easy, relaxed hops; the trip from Chicago to New Orleans requires but one day of solo flight; the trip from Seattle to San Francisco is delightful and takes merely a few hours. Flying in a private airplane can become the most liberating of all hobbies.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Cardiac Catheterization: Risks, Inconveniences, Indications and Contraindications: Study Based on 500 Observations. F. Rovelli. Minerva med. 49:4102-4111 (Nov. 3) 1958 (In Italian) [Turin, Italy].

The author reports on 500 cardiac catheterizations performed for diagnostic purposes on 469 patients, between 4 months and 52 years of age, with congenital or acquired cardiopathy. Of 231 patients with acquired cardiopathy, stenosis of the mitral valve was present in 98, defect of the mitral valve associated with other disturbances in 104, constrictive pericarditis in 16, and other disorders in 13. Of 238 patients with congenital cardiopathy, cyanosis was present in 81. Cardiac catheterization was carried out in 68 patients while they were under general anesthesia. In the course of cardiac catheterization, venous spasm developed in 3 patients and arrhythmia in 50. Episodes of nodal and atrial extrasystoles were common but well tolerated. Atrial fibrillation developed in 1 patient and paroxysmal tachycardia in 2. Acute pulmonary edema developed in 4 patients—in 2 during and in 2 after the catheterization. Complications after use of the catheter included chills (which developed in 19 patients), mild febrile episodes (in 75), and benign phlebitis of veins of the arms (in 8). The deaths of 3 patients, which can be attributed to use of the catheter, were related to pulmonary edema in 2 and to cardiac arrest because of anoxemia, which developed during the anesthetic state, in 1.

To minimize complications of cardiac catheterization, the author suggests the use of flexible catheters, careful sterilization of the catheter, precise premedication, application of gas narcosis and possible blood transfusions for children, and insertion of the catheter into the left basilar vein or into the saphenous vein if the basilar vein is too narrow. He also suggests infusion of apyrogenic solutions, the strict observance of asepsis, use of electrocardiograms, roentgenologic observations, and oximetry during the procedure, if possible, limiting the duration of the catheterization to as short a period as possible, and performance of the catheterization by an experienced team. Cardiac catheterization is a valuable therapeutic tool, but its application must be individualized, taking into aaccount its limitations and hazards.

Experiments on the Antituberculous Activity of Alpha-Ethyl-Thioisonicotinamide. N. Rist, F. Grumbach and D. Libermann. Am. Rev. Tuberc. 79:1-5 (Jan.) 1959 [New York].

The antituberculous activity of alpha-ethyl-thioisonicotinamide has been tested in vitro and in experimental animals. Although this compound is a derivative of isonicotinic acid, it is not a derivative of isoniazid. It has proved to be highly active both in vitro and in vivo against strains of tubercle bacilli that are resistant to isoniazid. It is 4 times more active in vivo than thioisonicotinamide, but its toxicity is not greater than that of the latter compound. Qualitatively, the effect induced by alpha-ethyl-thioisonicotinamide is similar to that of isoniazid; quantitatively, it is twice as effective as streptomycin and one-tenth as active as isoniazid in experimentally infected guinea pigs. Its toxicity in mice is only one-fifth that of isoniazid. When alpha-ethyl-thioisonicotinamide is administered by the oral route to man, it has been found in the serum in a biologically active form. The results of these studies accordingly justify the clinical trial of this compound.

Observation on the Antituberculous Effectiveness of Alpha-Ethyl-Thioisonicotinamide in Tuberculosis in Humans. G. Brouet, J. March, N. Rist and others. Am. Rev. Tuberc. 79:6-18 (Jan.) 1959 [New York].

A clinical investigation was carried out with the administration of alpha-ethyl-thioisonicotinamide in 102 patients with pulmonary tuberculosis; 73 were men and 29 were women. Fifty-seven of the patients had recent tuberculosis, and 45 had chronic tuberculosis. A thorough physical examination, roentgenologic study, and culture of sputum and of gastric washings for Mycobacterium tuberculosis had been frequently carried out in each patient. All strains of tubercle bacilli isolated were tested in vitro for susceptibility to alpha-ethyl-thioisonicotinamide, to isoniazid, and to other common antimicrobial drugs. Alpha-ethyl-thioisonicotinamide was administered orally, the usual regimen being 1 Gm. daily, or 4 tablets, given either as 2 tablets

---

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

twice daily or in the individual dosage of 0.25 Gm. at 6-hour intervals throughout the day. This compound was often not well tolerated and gave rise to side-effects, such as anorexia, nausea, or gastric irritation; the patients either ceased to gain weight or actually lost weight. There was no evidence, though, that it had a toxic effect on the liver, the kidneys, or the hematopoietic system, and it seemed to have a minimal neurotoxic activity, which required special attention only in patients treated concomitantly with isoniazid or cycloserine.

The treatment with alpha-ethyl-thioisonicotinamide had a beneficial effect on the clinical course, on the roentgenologic aspects, and on the bacteriological findings of patients with pulmonary tuberculosis. The bacteriostatic effect of this compound was particularly pronounced in patients with recent tuberculosis, and resolution was obtained within 2 or 3 months after institution of therapy in a large number of patients. The action of this drug, however, was not constant. The condition of some patients did not improve, and the emergence of bacterial resistance to alpha-ethyl-thioisonicotinamide occurred in several patients, but without evidence of decreased sensitivity to other bacteriostatic agents. After the administration of other orthodox antimicrobial drugs rapid improvement occurred in these patients.

Alpha-ethyl-thioisonicotinamide should not be administered alone, but only in conjunction with other antibacterial drugs, such as isoniazid, or isoniazid and streptomycin. It was found in this series that the combined treatment was very effective in patients with advanced pulmonary tuberculosis who had been treated previously, and it was active against strains of tubercle bacilli that were resistant in vivo to isoniazid and streptomycin. The authors believe, on the basis of the present experimental clinical investigation, that a study on the triple-drug regimen, consisting of isoniazid, streptomycin, and alpha-ethyl-thioisonicotinamide, is permissible in order to determine more precisely its effectiveness in patients with progressive pulmonary lesions.

Observations on the Administration of Kanamycin to Patients with Tuberculosis. K. W. Wright, A. D. Renzetti Jr., J. Lunn and P. A. Bunn. Am. Rev. Tuberc. 79:72-77 (Jan.) 1959 [New York].

Kanamycin, a new antimicrobial drug which is effective in low concentrations in vitro against tubercle bacilli, has been administered by the intramuscular route to 11 patients with chronic pulmonary tuberculosis. The ages of the patients ranged from 9 to 57 years. Sputum cultures for acid-fast bacilli were positive in all patients, and all strains of tubercle bacilli were resistant to streptomycin, isoniazid, and PAS. The inhibitory blood concentrations were produced and maintained for 8 hours with a daily dose of 0.5 Gm. of kanamycin. Impaired hearing resulted in 2 patients after the daily administration of 1 Gm. of kanamycin. Granular casts appeared in the urine of all patients within 14 or 28 days of treatment. There was no evidence that the drug had a toxic effect on the liver, on the vestibular apparatus, or on the hematopoietic system. No significant sensitivity reaction to the drug occurred in these patients, other than eosinophilia which was common. The rapid appearance of strains of tubercle bacilli highly resistant to kanamycin suggests that in prolonged treatments this drug should be administered only in conjunction with other antituberculous agents. The disappearance of tubercle bacilli from the sputum of one patient and the favorable changes in the sputum volume, in the body weight, and in the chest roentgenograms in some patients indicate that the drug is sufficiently effective to warrant further clinical trial.

Diagnosis and Therapy of Cushing's Syndrome. A. Labhart, E. R. Froesch and W. Ziegler. Schweiz. med. Wchnschr. 89:44-53 (Jan. 10) 1959 (In German) [Basel, Switzerland].

The authors discuss the histories of 10 patients (9 women and 1 man) with adrenal cortical hyperfunction (Cushing's syndrome) observed in the medical clinic of the University of Zurich before October, 1957. Autopsy reports were available in 2 of the cases, and in 7 patients, who had undergone adrenalectomy, the adrenals could be examined. An adenoma was found in the adrenals of 1 patient, whereas the adrenals in the other 8 patients showed hyperplasia. Although in one of these patients the hyperplasia was not detectable on naked-eye inspection, the histological examination in this and the other patients with hyperplasia revealed changes, such as adenoma-like sections in the cortex, obliteration of the cortical stratification, and cellular strands resembling fasciculated tissue. Studies on the hypophysis in the 2 autopsies revealed in one patient a basophil adenoma and in the other slight basophilism, in addition to metastases of a squamous-cell carcinoma. The excretion of hydrocortisone, ascertained on the basis of the 17-hydroxycorticoids, either was greatly increased or was in the upper limits of normalcy, but in 2 patients, in whom the aldosterone excretion was examined, reduced values were found, and one of these had hypopotassemia. The mineralocorticoids were not involved in the hypersecretion, the shifts in the electrolytes and the alkalosis being caused by the hydrocortisone.

An average of nearly 3 years elapsed between the appearance of the first symptoms and the correct diagnosis; in one patient the syndrome was recognized after 3 months. The most frequent of the clinical symptoms of Cushing's syndrome was a plethoric appearance with the characteristic moon-face; this was observed in all 10 patients. Hypogonadism was observed in 6 of the 10 patients: 5 of 8 women had amenorrhea or oligomenorrhea, and the man had impotence and azoospermia. Obesity, particularly of the trunk, was observed in only 4 patients. Hypertension occurred in 6 patients, but it was not severe. Osteoporosis was present in 7 patients and was severe in 2. Typical red striae existed in 4 patients, and 4 others had areas of superficial bleeding. Diabetes, as evidenced in reduced sugar tolerance, existed in 8 patients. Unusual features observed in this group of patients included: a sibship with polyadenomatosis (hyperparathyroidism, islet adenoma, etc.); the occurrence of adrenal hyperplasia secondary to an invasive pituitary adenoma composed of chromophobe-basophilic-mucoid cells; and the association with bronchial carcinoma, with creatinuria and severe muscular dystrophy, with testicular atrophy, and with irreversible secondary adrenal insufficiency after operation on an active adrenal adenoma.

In addition to the cardinal symptoms, the diagnosis of Cushing's syndrome depends on the 48-hour intravenous corticotropin tolerance test with determination of the urinary steroids. Regarding the treatment, the authors say that no reliance can be placed on the rare occurrence of a spontaneous remission, the less so since untreated Cushing's syndrome is usually fatal within 5 years. Irradiation of the pituitary is sometimes effective, but the recurrence rate is high. Bilateral total adrenalectomy and subsequent substitution therapy are presently the treatment of choice of bilateral adrenal hyperplasia.

The Natural History of Tuberculosis in the Human Body: I. The Demonstrable Primary Pulmonary Infiltrate. J. A. Myers. Am. Rev. Tuberc. 79:19-30 (Jan.) 1959 [New York].

A group of 300 children with primary pulmonary tuberculous infiltrates, ranging in age from 2 months to 20 years, were examined between May, 1921, and November, 1941. The primary infiltrates in these children varied in size from those scarcely large enough to be demonstrable to big dense homogenous areas; they were not limited to any lobe or area, some appearing even in the apexes of the upper lobe. The roentgenograms did not visualize characteristic shadows; therefore, differentiation from other diseases, even from the reinfection type of tuberculosis, was rendered difficult. After a few months the primary infiltrates began slowly to resolve, and within a year the shadow-casting lesions disappeared, except for the roentgenologic evidence of calcific deposits at the sites of the original lesion or in the hilar region or both.

Of the 300 children, 267 were followed up; 10 were not examined; and 26 had died. The cause of death was attributed to tuberculosis in 9, the disease being the acute, rapidly fatal forms in 7 (meningitis, pneumonia, and miliary dissemination); the other two patients died of chronic pulmonary tuberculosis 8 and 19 years, respectively, after the primary pulmonary infiltrate was detected. Among the 231 survivors who were examined, the reinfection type of chronic clinical tuberculosis developed subsequently in 9, but it occurred in the region of the primary infiltrate only in 1. The remaining 222 patients have no evidence of any clinical disease.

While mortality and morbidity to date may seem small, it may still be considerably increased, because the subjects under consideration have not lived the halfway mark of natural span of life. The benign character of the demonstrable primary pulmonary infiltrate is no assurance against the development of a chronic disease, because foci that continue to harbor tubercle bacilli may subsequently release organisms that result in clinical lesions.

SURGERY

The Advantages of Early Spine Fusion in the Treatment of Fracture-Dislocation of the Cervical Spine. H. F. Forsyth, E. Alexander Jr., C. Davis Jr. and R. Underdal. J. Bone & Joint Surg. 41A:17-36 (Jan.) 1959 [Boston].

The authors report on 72 male and 9 female patients, between the ages of 8 months and 75 years, with fracture-dislocation of the cervical spine who were considered for internal fixation and spine fusion early in their course of treatment. Fifty-one of the 81 patients sustained their injuries in an automobile accident; the injuries of 12 were produced by falling, those of 6 by diving, those of 3 by gunshot, and those of the remaining 9 by miscellaneous causes. Of these 81 patients, 35 were treated with fusion and 46 were treated conservatively. Recurrence of the deformity developed in 3 of the 46 patients treated conservatively, and fusion was subsequently done. Thus, a total of 84 cases were analyzed. In the treatment of cervical spine injuries, first consideration must be given to protection of the neural structures. Relieving all pressure from the spinal cord and nerve roots and putting them at rest afford the best opportunity for return of function of the neural structures. To do this with certainty requires accurate reduction of bone structures, followed by internal fixation for immediate stability and spine fusion to prevent late recurrence. The general routine of skeletal traction, internal fixation, and spine fusion constitutes a method of treatment that needs to be varied only slightly in order to be practiced in a large percentage of all serious injuries of the cervical spine.

The results obtained in the 35 spine fusions and in the 46 injuries treated conservatively indicate that the patients in whom fusion was done had less residual deformity and a lower rate of recurrence.

In addition, less time was spent in the hospital or in uncomfortable casts, and less time was spent away from work. The mechanism of injury in fracture-dislocation of the cervical spine is discussed in some detail, with emphasis on the hyperextension fracture-dislocation which is caused by a combination of forcible extension and compression acting from above. A new interpretation of the roentgenologic findings in a large group of fracture-dislocations with mild anterior displacement showed that about 50% of them were caused by hyperextension rather than flexion as previously thought. Before this mechanism was recognized, it was difficult to understand the severe neurological changes that were frequently present. Placing these cases in the group of hyperextension injuries makes the neurological damage understandable.

Brain Abscess. C. V. M. Fog. Danish M. Bull. 5:260-264 (Dec.) 1958 (In English) [Copenhagen].

Fog reviews 114 cases of brain abscess in 89 males and 25 females, representing all age groups. The localization was in the brain stem in only 2 cases, was supratentorial in 11, and was infratentorial in 12. In 33 cases the abscess was otogenic; in 6, rhinogenic; and in 28, thoracogenic. In 11 cases it was due to cranial injuries, in 36 to other causes. The most frequent cause was infection from the ears and nose; the next most frequent cause, infection from the lungs. The bacterium most often found in cultures from pus was Staphylococcus aureus. The mortality was highest in cases with brain abscess of thoracogenic origin. The prognosis is best for sterile abscesses and least favorable in cases with streptococci. Diagnosis may be difficult. A brain abscess may be present without demonstrable leukocytosis or choked disk. Most of the patients were treated by total excision, which was usually preferable to more conservative methods. The mortality has fallen steadily since the advent of penicillin and the introduction of rational chemotherapy, with resistance determinations as a guide in the choice among streptomycin, tetracyclines, chloramphenicol, sulfonamides, and penicillin, but it is still about 25%. Fifty-five of the 59 survivors were followed up. Six had died of other diseases. In the remaining 49, the late prognosis was found to be best for the infratentorial cases. Almost half of the patients with supratentorial abscesses had reduced working capacity.

Experience with Arterial Replacement. H. W. Scott Jr., J. A. Kirtley, R. I. Carlson and J. H. Foster. J. Tennessee M. A. 52:1-3 (Jan.) 1959 [Nashville].

The authors report on 183 patients with vascular disease on whom arterial grafting was performed at the Vanderbilt University Hospital and the Thayer Veterans Administration Hospital in Nashville, Tenn., since 1954. A freeze-dried homologous homograft was employed in 149 patients, and a synthetic prosthesis in 34. Arteriosclerotic aneurysm of the abdominal aorta and arteriosclerotic occlusive disease of the terminal aorta were the 2 commonest indications for arterial grafting in the group of 149 patients; 21 of them died, representing a mortality rate of 14.5%. Segmental arteriosclerotic occlusion of a peripheral artery was the commonest indication for grafting in the group of 34 patients; 4 of them died, representing a mortality rate of 12%.

All the abdominal aneurysms in this series originated below the renal arteries and allowed anastomosis of the grafts, after resection of the aneurysm, without encroachment on the renal vessels. In many of the patients with arteriosclerotic occlusion of the terminal aorta (Leriche's syndrome), blood flow to the extremities was improved by employing bypass grafts from the aorta to the femoral arteries without disturbing collateral vessels in the region of the aortic bifurcation. Bypass grafts were also employed for segmental occlusions of the femoral artery. In other arterial lesions, resection and restoration of normal circulation were performed by graft implantation. The patients were followed for periods of up to 4½ years. The results were good. There was no recurrence of symptoms, and there was good maintenance of function. The incidence of thrombosis in grafts was low (5% in the group with homografts and about 10% in that with synthetic prostheses), and there was no evidence of aneurysmal dilatation of any grafts. Aortograms performed as late as 3 years after graft implantation showed maintenance of structural integrity of the arterial substance. While freeze-dried arterial homografts have functioned well, it is likely that the improved synthetic prostheses curently available will largely replace the homografts as arterial substitutes.

Prognosis in Lung Cancer Surgery Based on Blood Vessel Invasion. E.-D. Gagnon and C. Gelinas-Mackay. Canad. J. Surg. 2:156-160 (Jan.) 1959 [Toronto].

At Notre-Dame Hospital in Montreal during the 9 years from 1949 to 1957, a total of 329 cases of lung cancer were diagnosed, of which 254 were histologically verified by bronchoscopic examination, biopsy of lymph nodes, thoracotomy, or autopsy. In only 77 (30%) of the verified cases was a surgical attempt at cure possible. Of the 77 patients, only 48 could undergo resection. Eleven of these died within 30 days after surgery, leaving 37 who could be followed up. The surgical specimens of these 37 survivors were studied, special attention being given to the invasion of the blood vessels. All patients surviving and "well" for more than 2 years had no blood vessel invasion in the removed lung, and patients dying of other causes likewise had no blood vessel invasion. However, all but one of the patients dying of metastases had blood vessel invasion.

The obliteration of lung vessels by proliferation of the intima seems to be an effective barrier against metastases. The histological type of the carcinoma does not seem to influence the prognosis directly. The presence or absence of blood vessel invasion, more than any other criterion, seems to be important in the prognosis of lung cancer. More attention should be paid to this as an aid to prognosis. Operation at the earliest possible time affords the only chance of cure.

Carcinoma of the Stomach: Follow-Up Investigation in 451 Cases. M. Andreassen. Danish M. Bull. 5:264-268 (Dec.) 1958 (In English) [Copenhagen].

The material comprises 451 cases of carcinoma of the stomach in 319 men and 132 women who were treated from 1945 to 1955 in the Rigshospitalet, Copenhagen. The disease occurred predominantly in the 5th and 6th decades of life. Four patients were under 30 years of age; in such cases the prognosis is usually less favorable, because at this early age the diagnosis of cancer is often overlooked. Only 40 patients sought treatment within 3 months after the development of symptoms. Radical operation was performed in 211 cases, or 47%, with a 3-year survival rate of 21%. The author stresses the importance, in surgical treatment of cancer of the stomach, of more extensive employment of histological examination of the edges of the resection during the operation, with meticulous removal of the lymph nodes and fat from the stomach bed, especially from the hepatic pedicle. Possibly total gastrectomy can be employed to a greater extent if supplemented by an intestinal reservoir introduced between the esophagus and the stomach. Increased palliative resection is recommended in cases in which the tumor cannot be removed radically.

A Contribution to the Knowledge of Saint's Triad (Hiatal Hernia, Gallstones, and Diverticulosis). E. Fedele and L. Sabatini. Policlinico (sez. chir.) 65:243-253 (Oct.) 1958 (In Italian) [Rome].

The authors report on 2 women, 44 and 52 years of age, with Saint's Triad, who were observed at the surgery clinic of the University of Rome during one year. The first patient 4 years before observation felt some pain in the epigastric region. This symptom became more intense and more frequent. No direct relationship between the pain and the digestion was apparent. The patient complained also of a burning sensation in the retrosternal region, which became more severe during hiccups. Difficulty in the digestion of especially fatty foods occurred 2 years before observation; half an hour to 2 or 3 hours after meals the patient suffered pain which originated in the epigastrium and extended to the right of the hypochondrium. One year before observation occasional diarrhea, with semiliquid feces at times mixed with mucus, was noted. Roentgenologic examination showed a hiatal hernia of the sliding type at the fundus of the stomach, and diverticula were seen in the cecum, in the transverse colon, and at the hepatic flexure of the colon. Cholecystography showed 2 transparent calculi at the fundus of the gallbladder. The second patient complained of pain, vomiting, and, rarely, some fever for 14 years before coming to the clinic; these symptoms became more frequent with time. Two years before observation she suffered a sensation of burning in the retrosternal region. Over the years she had made frequent use of laxatives. A large swelling could be felt in the iliac fossa on the right. Roentgenologic examination showed a gastroesophageal reflux; the lower part of the stomach appeared partially herniated through the esophageal hiatus. A mass, the size of a big orange, was noted in the small intestine. Diverticula were seen in the ascending and the transverse colon, and gallstones were noted in the gallbladder.

The authors think that what is usually referred to as Saint's Triad is a syndrome, and that the presence of the 3 pathological manifestations (hiatal hernia, gallstones, and diverticulosis) is a mere coincidence and is not due to a common cause. The association and the interrelation of the manifestations are worthy of investigation in order to remove the lesion which is most responsible for the syndrome.

GYNECOLOGY & OBSTETRICS

Exchange Transfusion in Treatment of Septic Toxemia Due to Clostridium Perfringens. G. Villavicencio G., A. Hille and C. Paredes. Obst. y ginec. latino-am. 16:255-265 (July-Aug.) 1958 (In Spanish) [Buenos Aires].

Eight women with septic toxemia due to Clostridium perfringens after an induced abortion were observed during 1957-1958 at the San Borja Maternity Hospital of Santiago, Chile. The patients were hospitalized 48 to 96 hours after the induced abortion. They were in acute shock (2 being in a condition of irreversible shock), with severe hemolytic anemia, marked hemoglobinemia and hemoglobinuria, jaundice, and uremia with marked oliguria or anuria. During the first day of hospitalization the patients were treated by curettage and administration of antibiotics and perfringens antitoxin, and received a direct transfusion of from 8 to 10 liters of fresh blood. The technique was the same as that used in an indirect transfusion with fresh blood, the injection being given into the cephalic or the jugular vein. Uremia, creatinemia, and uricemia diminished in 2 or 3 days, and diuresis reappeared after the first exchange blood transfusion in 3 out of 5 patients. In the other 2 patients a second transfusion of the same quantity of fresh blood was necessary 4 days after the first for obtaining satisfactory results. One patient had 3 such transfusions during a 24-day period of anuria; diuresis reappeared after the third and last transfusion. The results show recovery of the patients in 75% of the cases. The authors conclude that exchange blood transfusion should constitute a routine treatment of septic toxemia due to perfringens after an induced abortion, being given at the same time that antibiotics and perfringens antitoxin are.

Fluoxymesterone (Halotestin) in the Treatment of Advanced Breast Cancer. K. B. Olson. New York J. Med. 59:248-252 (Jan. 15) 1959 [New York].

Fifteen women, between the ages of 39 and 72 years, with advanced cancer of the breast, were treated with a new halogenated corticosteroid, fluoxymesterone (Halotestin). Thirteen of the 15 patients had previously undergone radical mastectomy, and 8 had been treated previously with either androgens or estrogens. Two patients were premenopausal and had previously been castrated without remission of their disease. One patient was treated on exacerbation of her disease after a remission resulting from hypophysectomy. Fluoxymesterone was initially administered in doses of 10 mg. per day orally. This dose later was increased in all patients to 20 mg. daily. Subjective improvement of some degree, consisting of a sense of well-being, increase of appetite, and a decrease of pain, occurred in 6 patients. Objective improvement, as measured by healing of skeletal lesions and reduction of the size of lymph nodes by more than 50%, occurred in 4 of these 6 patients. The patient who previously had a hypophysectomy had a short objective remission. The 2 menstruating patients who failed to respond to surgical castration likewise failed to respond to fluoxymesterone therapy. Eight patients received no benefit from fluoxymesterone therapy, and all of them subsequently died. Two of the 4 patients with objective improvement died. The usual effects of androgenic hormones were noted in most of the patients continuing therapy for more than one month, as evidenced by hirsutism, acne, increased libido, edema, and increased erythropoiesis, but the impression was gained that these effects were slower to occur and were not of such magnitude as those with testosterone propionate and methyltestosterone.

Fluoxymesterone appears to be a potent androgen and capable of producing objective remission in advanced breast cancer. It has the advantage of being administered orally and is well tolerated in effective doses. It is not known whether doses of more than 20 mg. per day will be more effective, but no remissions were noted with doses lower than that amount. It seems probable that fluoxymesterone is at least as good as other effective androgens and deserves further trial.

PEDIATRICS

Phenylketonuria: An Unusual Case. S. A. Leonard and F. L. McGuire. J. Pediat. 54:210-214 (Feb.) 1959 [St. Louis].

The authors report on an 8¼-year-old girl with phenylketonuria. Physically the child was relatively normal except for her height (47½ in. [120 cm]), which was below the 16th percentile; her weight was normal. Psychological evaluation revealed an intelligence quotient of 70, which would place her within the borderline mental deficient category. Her serum phenylalanine level was 36.5 mg. per 100 cc. and thus did not correlate with her IQ. A routine ferric chloride test gave positive results. The child was found high in ability for rote memory, and it was felt that increased mental age might be obtained with continued environmental security. She was not treated with low-phenylalanine diet because of poor experimental results in older children; in addition, she was asymptomatic. A brief review of the literature showed that the first descriptions of phenylketonuria were all those of severe mental retardation. Psychologically this child was found to be a "phenylketonuric" and not a "phenylpyruvic oligophrenic." The authors believe that "phenylpyruvic oligophrenia" is no longer a correct term for the syndrome of phenlyketonuria, and that the report of this patient may add stimulus to the broadening of the spectrum of phenylketonuria.

Thyroid Cancer in Children. J. R. Moore and A. D. McKenzie. Canad. J. Surg. 2:175-179 (Jan.) 1959 [Toronto].

The authors present the histories of 6 children with thyroid carcinoma, who were observed in the Vancouver area between 1952 and 1957 inclusive. Malignant thyroid tumors in adults were likewise reviewed, and it was found that children accounted for 5% of the group. The children ranged in age from 7 to 17 years, and all but one were boys. That thyroid carcinoma in children is not readily suspected is proved by the fact that in 4 of the children symptoms had been present for from 5 to 18 months. The other 2 children had symptoms for one month each. The finding of a thyroid nodule or nodules in children is more serious than in an adult, and the majority are likely to be carcinoma. It can be expected that the presence of masses in the neck will be the initial sign. As with papillary carcinoma in adults, a considerable number of children will have metastatic lymph node involvement when they are first seen. There were 4 such patients in this series, and one of these had lymph node enlargement as the only clinically demonstrable lesion. Only 2 of the 6 patients had localized thyroid nodules, both on clinical examination and at operation.

Histologically, 5 patients had a papillary adenocarcinoma, while the remaining patient had a papillary follicular type of lesion. Since 1950 there have been several reports on previous irradiation in children who later developed cancer of the thyroid. All 6 of the patients in this series had received irradiation for an "enlarged thymus gland" during infancy. The total dosage in each instance was about 500 r. Surgical excision was the primary treatment in all the patients. External irradiation was used in 2 patients, in one of whom local removal was not complete. Radioiodine (I^{131}) was helpful in one patient. The 2 children with the localized disease are well with no clinical evidence of recurrence, one after 5 years. Residual or recurrent disease is present in the other 4 patients.

A Contribution to the Knowledge of the Christmas Factor Deficiency in Infants. W. Felici and V. Bacchetta. Minerva pediat. 10:1226-1234 (Nov. 3) 1958 (In Italian) [Turin, Italy].

The authors discuss the histories of 2 children with deficiency of the plasma thromboplastic component (Christmas factor). The first child, at the age of 3½ years, had developed a swelling of the left knee because of a fall. The swelling persisted unchanged and painful for 25 days. During the following 2 years the condition improved only upon immobilization of the joint and returned to the initial state whenever attempts to move the knee were made. The child was brought to the hospital at the age of 6, and a diagnosis of hemophilia was made. One month before the last observation he had suffered a gingival hemorrhage. Moreover, owing to trauma to the left gluteal region incurred in a fall, he had developed a hematoma in the same region, with pain radiating into the thigh and the left popliteal region; the swelling regressed slowly and disappeared after 20 days. Coagulation tests gave normal results. The authors believe that hemophilia in this patient, who was the only male child in his immediate family, was hereditary. In taking the history it was revealed that a maternal uncle, at the age of 2 years, had had a profuse hemorrhage caused by a lacerated and contused wound on the forehead; later this relative suffered from rheumatism of the major joints and died at the age of 17 of unascertained causes.

The second child, who died after 2 days of life, showed at birth hemorrhage and plasma thromboplastic component (PTC) deficiency associated with prothrombin and factor VII deficiencies. The brothers of the child had not experienced any hemorrhages. The authors believe that in this child the PTC deficiency, combined with a deficiency of prothrombin and factor VII, was to be considered the result of disturbances in the production of coagulation factors of the plasma by the liver. Such disturbances are frequent in the neonatal age. The diagnosis of a hemophilic syndrome was excluded in this case, inasmuch as the PTC deficiency was not the result of a hemophilia-like disease (Christmas disease), which would imply the operation of hereditary influences, but was the result of functional immaturity or parenchymal alterations in the liver.

DERMATOLOGY

Cryoglobulins in the Chronic Lupus Erythematosus. T. Chorazak. Acta dermat.-venereol. 38:322-328 (no. 5) 1958 (In English) [Stockholm].

The author points out that the obscure etiology of the collagen diseases has led to explorations going beyond the dermatological field, being concerned with such factors as the erythrocyte sedimentation rate, the detection of L. E. cells (Hargraves' sign), and the investigation of the protein pattern of the blood serum. Investigators who studied the blood serum proteins by means of paper electrophoresis in dermatological conditions, and particularly in lupus erythematosus, found that there is a reduction in albumin and an increase in globulins, particularly the gamma globulin fraction. Cryoglobulin (Lerner and Watson's term [1947]) for a blood globulin precipitating in serum at a temperature of from 7 to 11 C [44 to 52 F] is also known as the "cold fraction." Even the presence of small amounts of cryoglobulins is pathological and is classified by the author as a paraproteinemia. Earlier investigators had demonstrated that the electrophoretic velocity of cryoglobulins is similar to that of gamma globulins and perhaps of beta globulins or lies between beta and gamma globulins.

The author investigated the presence of cryoglobulins in the serum of patients with chronic lupus erythematosus and found this "cold fraction" in 48 of 72 patients (67%). He regards this as an extremely high percentage, the more so since others, in examining the serums of 40 healthy subjects, never found cryoglobulins, and he himself failed to find them in 12 persons who were healthy or had only minor skin lesions. Practically all the 72 patients showed hyperglobulinemia, particularly of the gamma and less so of the beta fraction. Of 44 patients with hypergammaglobulinemia, 29 had cryoglobulins. Of 27 patients with hyperbetaglobulinemia, only 17 had cryoglobulins. The author feels that the high incidence of cryoglobulinemia in the patients with chronic lupus erythematosus suggests that this factor has some connection with the pathogenesis of the disease; at any rate, the presence of cryoglobulins cannot be regarded as of no importance, because it usually accompanies serious diseases. The site of formation of cryoglobulins is still controversial; some believe they are formed in the liver, and others in the muscles, in the reticuloendothelial system, in the mast cells or the plasma cells.

No correlation could be found between cryoglobulinemia and the severity of lupus erythematosus, although in 7 patients who had hyperglobulinemia, but no cryoglobulins, the local lesions had healed (thin, smooth scars with pigmented borders but without erythema, infiltration, or sealing). The lack of uniformity of the electrophoretic aspects of patients with lupus erythematosus permitted no definite conclusions. Hyperglobulinemia, with high values of gamma and beta fractions, was found to persist both in active lesions and in locally cured ones. Some observations on the patients studied by the author suggested that the cryoglobulins might be connected with the transition from a chronic to an acute form of lupus erythematosus, with increase in body temperatures, superficial ulcerations on hands and feet, pain and edema in the joints. Corticotropin and cortisone have been observed to cause partial or complete disappearance of cryoglobulins, and it is suggested that this mechanism might be responsible for the beneficial effect of these hormones in lupus erythematosus.

Plantar Wart Treatment with Ultrasound. H. Kent. Arch. Phys. Med. 40:15-18 (Jan.) 1959 [Chicago].

This report is concerned with the use of ultrasonic wave lengths in the treatment of plantar warts. The equipment used in all treatments was a Birtcher Ultrasonic Model No. 105-F, having a frequency of 1 megacycle. The transducer or soundhead is able to deliver a total energy of 0.5 to 15 w. The crystal contained in this transducer is 5 sq. cm. in area and is designed to deliver an output of 0.1 to 3 w. of ultrasonic energy per square centimeter. The coupling medium used on all patients was liquid petrolatum (white mineral oil) U. S. P., a low viscosity fluid which also acts as a lubricant, so that all areas of skin are kept in contact. A gentle firm pressure of the soundhead was maintained during treatment and a rotatory motion employed. The duration of treatment was arbitrarily kept to 15 minutes. With this technique, no complaints were received concerning heat effects or pain. On the contrary, when a wart had been painful, almost complete relief was obtained after the first 5 minutes of treatment.

Nine patients were treated. As a rule, single, discrete, recent plantar warts were preferred. Two patients had multiple warts. The frequency of treatments varied from a single to 11 courses. Of the patients described, one had previously been treated with maximum x-ray doses on isolated warts on both feet. The warts were approximately 2 mm. in diameter, circumscribed by fibrous tissue, and only slightly elevated from the surrounding skin. Bunion pads had been employed because the warts were quite painful. Only the lesion on the left foot was treated with ultrasonic waves. The wart on the right foot served as a control. After the 8th dose, the wart appeared to become more elevated. Pain recurred, but after the wart was sanded down with emery paper, comfort was restored. The lesion became smaller until finally a minimal scar remained. Six months later, the treated wart had not recurred, whereas the wart on the untreated foot remained unchanged.

The general results suggest that ultrasonic therapy is nearly always effective in the treatment of plantar warts. Pain is relieved almost immediately, followed by necrosis of the wart. Normal skin is unharmed by the technique. Changes evoked in these warts suggest either a vascular, a molecular, or a viral effect. Advantages of ultrasonic therapy of plantar warts include quick pain relief and the fact that it involves neither paring nor skin destruction nor scarring nor protective pads, that the patient remains ambulatory, that single warts in difficult locations (edge of heel) can be treated, and that recurrences are apparently prevented.

PUBLIC HEALTH

Report on Edinburgh X-Ray Campaign, 1958: Introduction and Community Arrangements: Technical and Administrative Arrangements: Results of Campaign. H. E. Seiler, A. G. Welstead and J. Williamson. Tubercle 39:339-359 (Dec.) 1958 [London].

The authors report on an x-ray campaign conducted in Edinburgh in 1958. A cooperative effort by local authority, local hospital authority, and the central department of health, with the good will and help of local community workers, achieved an 84.4% response of the public to the request to have chest x-rays taken. The technical and administrative arrangements proved adequate but only as a result of detailed previous planning. Four hundred twenty-three new patients with active pulmonary tuberculosis were found. The highest prevvalence of active tuberculosis was in males over 60 years of age (3.30 per 1,000). The over-all prevalence in males was 2.17 and in females 1.01 per 1,000 persons x-rayed. The importance of older men in the epidemiology of tuberculosis has once again been emphasized. It is noteworthy also that in these men the prevalence of carcinoma was as high as 2.34 per 1,000. It is concluded that an x-ray campaign of this sort is a useful and justifiable method of case finding for tuberculosis and other serious chest diseases. It is particularly suitable in communities where tuberculosis appears to be coming satisfactorily under control, and it may advance the day of final conquest of the disease by several years.

BOOK REVIEWS

The Effect of Advancing Age upon the Human Spinal Cord. By L. Raymond Morrison, M.D., with collaboration of Stanley Cobb, M.D., and Walter Bauer, M.D. Cloth. $6. Pp. 127, with illustrations. Published for Commonwealth Fund by Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, England, 1959.

It is regrettable when it is not possible to write a favorable review of a book published posthumously. Unfortunately, this book fails in the purpose for which it was written; the changes in the spinal cord which result from advancing age are not presented in an intelligible manner. The material on which this study was based has been poorly chosen. These spinal cords were taken from the bodies of persons who died from a variety of systemic diseases such as rheumatic heart disease, lupus, ulcerative colitis, lymphoblastoma, and uremia. At least two of the patients had a pyramidal tract lesion, and at least one of these was from cerebral infarction. The reader is not informed as to the cause of death in all of the patients, nor is he given any information by means of which he might discriminate between the anatomic changes produced by aging and those resulting from disease processes. The author does not attempt to make such a differentiation, and one doubts if such could be made with accuracy on this material. It is surprising to learn that "The brains were not examined in this series." Even the changes which were observed have not been organized in a systematic fashion, and no clear-cut picture is presented of the changes produced by advancing age.

The poor sentence structure and unfortunate choice of words are striking. This monograph has been published with the aid of money from a fund established to support scientific research. The lack of a scientific approach to the problem in hand is disturbing. As if to expand a very short text into a book of even this small size, the publisher has resorted to extremely wide margins and to the use of illustrations two and three times as large as they need to be. Only the first 52 pages of this book are devoted to the subject of the title. The rest consists of an atlas of sections, stained by the Weigert and Nissl methods, of a "normal spinal cord" removed from a 24-year-old woman who died of subacute bacterial endocarditis with an occasional focus of abnormality within the spinal cord. The Weigert preparations are in no way unusual, while the sections stained by Nissl's method are reproduced at such a low magnification as to be of little value. There is no index.

Cancer. Volume 2, Part II: Pathology of Malignant Tumours. Volume 3, Part III: Additional Pathological Aspects; Part IV: Geography of Cancer; Part V: Occupational Cancer; Part VI: Cancer Education; Part VII: Cancer Detection. Edited by Ronald W. Raven, O.B.E., T.D., F.R.C.S., Joint Lecturer in Surgery, Westminster Medical School, University of London, London. Cloth. $18 per volume. Pp. 641, 25, with 357 illustrations; 483, 18, with 165 illustrations. Butterworth & Co., Ltd., 88 Kingsway, London, W. C. 2, England; 1367 Danforth Ave., Toronto 6, Canada, 1958.

Cancer. Volume 4, Part VIII: Clinical Aspects. Edited by Ronald W. Raven, O.B.E., T.D., F.R.C.S. Cloth. $126 per set of 7 volumes. Pp. 532; 23, with 173 illustrations. Butterworth & Co., Ltd., 88 Kingsway, London, W. C. 2, England; 1367 Danforth Ave., Toronto 6, Canada, 1958.

The first volume of this six-volume British compilation on cancer was reviewed in The Journal of the American Medical Association for March 8, 1958, page 1257. The review was favorable and concluded that every investigator and student of cancer should have access to the work. This opinion is hard to maintain after the examination of these three subsequent volumes. Volumes 2 and 4 deal with human cancer by the major anatomic sites of the neoplasms, volume 2 being on pathology and volume 4 on clinical aspects. This separation is unattractive to this reviewer, particularly since radiotherapy is relegated to the forthcoming volume 5. As a result, for carcinoma of the uterine cervix, pathology is to be found in volume 2, certain clinical features in volume 4, radiotherapy in volume 5, and cytodiagnosis in a section of a chapter in volume 3. The presentation of this and other important human neoplasms becomes choppy, closely interrelated aspects are torn apart, and some important considerations are barely touched on while others are unnecessarily duplicated.

Volumes 2 and 4 are written almost entirely by British authors. In general, the concepts and practices of pathology and of clinical management of cancer do not differ significantly from those of a similar cross-section of authorities who might have been selected in the United States. Differences do appear, however, more related to individual experiences than to national practices. For example, the editor contributes a 20-page chapter on the clinical aspects of breast cancer. The advice regarding treatment is, for clinical stage 1, radical mastectomy and postoperative radiation; for clinical stage 2, preoperative radiation followed by radical mastectomy. "Oophorectomy should be performed for all premenopausal patients . . . irrespective of the stage of disease." These recommendations would not be in agreement with the practices of many other centers. No other views are presented; the recommendations are not supported by

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

the limited statistics on end-results from the Royal Marsden Hospital; and that is all that is said about prognosis. In contrast, one whole page and 4 of 31 references are devoted to adrenalectomy and hypophysectomy, with the prospectus for volume 6 indicating additional separate chapters on each of these subjects.

The first chapter of volume 4 presents the subject of staging and emphasizes a "TNM" system that is still under discussion as a possible standard. It seems odd that no special consideration is given to end-results, survival analysis, or the duration of cancer among "untreated" patients, particularly since Great Britain has been the first to use biometric surveys and has some excellent regional and national cancer registries.

Volume 3 is divided into five main parts, including additional pathological aspects, geography of cancer, occupational cancer, cancer education, and cancer detection. The 23 chapters by 22 authors are of widely different quality, and the collection displays a lack of over-all editorial integration. The chapter on tissue culture is good, but it is directed to the growth of cancer cells, which obscures the recent difficulties in separating "normal" from "neoplastic" cells under conditions of in vitro culture. The chapter on neoplasms in domesticated animals should have been either much longer or much shorter. It has the appearance of editorial dissection, leaving some sections misleading in their incompleteness, and retaining such trivial data as a list of the most popular breeds of dogs in Great Britain and the United States. The best chapters in volume 3 are on the epidemiology of cancer, and this reviewer would have liked to have a whole volume devoted to these studies. The reports by Stocks, Dorn, and Clemmesen are particularly noteworthy, yet nowhere is it made clear that these population-based incidence analyses should not be compared directly with the relative distribution frequency studies from India and South Africa. The excellent chapters on occupational cancer of the skin and urinary bladder and leukemia could well have been extended to include occupational neoplasms of the lung and upper respiratory passages.

Cancer education is treated in chapters that appear to be essentially promotional progress reports of the sponsoring agencies. Only the paper by Wakefield presents the philosophy and the limitations of this field of endeavor. The two chapters on cancer detection, by O'Donnell and Day, are thoughtful, complete descriptions of more than passing value.

These three volumes, it is regretfully concluded, compare badly with several other textbooks on cancer. In the field of research "The Physiopathology of Cancer," edited by Homburger and Fishman, is certainly a more intelligently gathered collection, while for the clinical-pathological aspects "Cancer," by Ackerman and del Regato, retains its place as the best source in English. Knowledge about cancer is so incomplete that anything approaching a systematic compendium is an impossibility. The best that can be done is to collect the views of the recognized leaders in the field, without the illusion that these views are necessarily correct. Under these circumstances it might be desirable to print on the cover of such compilations of cancer data a warning to the reader, such as "Opinions contained herein are those of the authors and do not necessarily reflect the truth, especially when such opinions are presented as facts."

History of the Second World War: United Kingdom Medical Series. Editor-in-chief: Sir Arthur S. MacNalty, K.C.B., M.A., M.D. The Royal Air Force Medical Services. Volume III: Campaigns. Edited by Squadron Leader S. C. Rexford-Welch, M.A., M.R.C.S., L.R.C.P. Cloth. 105 *shillings*. Pp. 730, with illustrations. Her Majesty's Stationery Office, Atlantic House, Holborn Viaduct, London, E. C. 1, England, 1958.

This is the third and final volume of the Royal Air Force portion of the medical history of World War II. The volume consists of 721 pages, containing discussions of the principal campaigns in which the Royal Air Force participated. There are 67 plates, 58 maps, and 37 figures. The medical activities of the RAF are covered in 11 campaigns, extending geographically from the equator to the Arctic Circle. Medical conditions varied greatly, as one would expect, the problems of northern Russia being far different from those of equatorial Africa.

The plans made for continental Europe in 1939 had to be discarded after the destruction of the entire Polish Air Force in the first 48 hours of the invasion of Poland, and it became necessary to disperse all units. At times air squadrons were split up between air fields 30 miles apart, making executive and medical administration difficult. In addition, the weather during the winter of 1939-1940 was severe and temperatures fell at times to below 0 F. The losses due to enemy action from Sept. 3, 1939, to June 19, 1940, totaled 407 deaths and 632 wounded. The average strength during this period was 15,172, with an average number of casualties of over 48 hours' duration of 28.3 per thousand.

The Norwegian expedition was undertaken at short notice with little or no preparation. It was short-lived, however, and lasted only from April 20 to June 8, 1940. The campaign in Libya and Tunisia was a difficult one, operations commencing with the initial Italian advance into Egypt in 1940. Prior to this the RAF had several peacetime garrisons in Egypt with a strength of nearly 6,000. The provision of an adequate water supply in the desert was extremely difficult, due to both scarcity and poor quality. At times the troops were issued water with a saline content of 1,700 ppm. In certain places malaria was endemic. A condition known as "desert sores" was common; these were indolent ulcers of undetermined cause. Dysentery, typhoid, infectious hepatitis, typhus, and relapsing fever all occurred in the command.

It was during the Middle East campaign that air evacuation of sick and wounded was initiated. In March, 1941, the Australian government indicated its willingness to provide, staff, and maintain an air ambulance unit consisting of three converted DH-86 airplanes. Meanwhile, the RAF and the South African Air Force had converted a few airplanes, so that by November, 1941, 8 or 10 air ambulances were available for duty in the Middle East.

In the Greece and Crete campaign (1940-1941) suitable sanitary conditions were difficult to maintain. On Crete the RAF had its first encounter with air-borne troops as the Germans landed about 7,200 men on the first day. This number was augmented later and caused the withdrawal or capture of all British. The 151st RAF wing served in north Russia from September to November of 1941. There was little sickness in this command. Malta, West Africa, Italy and the Balkans, India, and the Far East were also the sites of RAF campaigns as was, of course, continental Europe prior to the liberation. The book is well written and easy to read. The only confusing thing to an American reader is the use of initials instead of complete names of units, installations, and activities. A glossary would prove useful.

Practical Blood Grouping. By F. Stratton, M.D., D.Sc., D.P.H., Director, Blood Transfusion Service, Manchester, and P. H. Renton, M.D., B.Sc., Deputy Director, Blood Transfusion Service, Manchester. Cloth. $9. Pp. 331, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This is the second book on blood grouping techniques that has been published in England in recent years. This book is more than a dry presentation of methods, since it gives a coherent account of blood group serology, and each point that is made is illustrated by a brief case history. Included in the book are 74 such cases, which enliven the presentation. The usefulness of this excellent review of blood group methodology, however, is seriously impaired by the inclusion of the same misconceptions and mistakes which have stigmatized the literature on blood groups for more than a decade. To mention only a few examples the authors cite with seeming approval the recent numerous investigations purporting to show an association between particular A-B-O groups and disease but fail to mention any of the criticisms which have been leveled against these reports by Wiener, Manuila, and others. The authors again cite as an established fact the highly questionable reports of rises in Rh antibody titers during pregnancy in sensitized Rh-negative women carrying Rh-negative babies.

The report of W. Weiner on the supposed anti-e specificity of autoantibodies tested by him, though poorly documented, has been widely accepted; and the authors of this book claim to have found a similar case of autoantibodies of anti-C+e specificity, although the flimsy evidence presented on page 242 appears to contradict rather than support this conclusion. The claims of anti-e specificity of autoantibodies by many other workers, not including A. S. Wiener, following the original report of W. Weiner, are reminiscent of the unsubstantiated claims of serums of anti-d specificity after Fisher's announcement of his "predictions." Probably, for every dozen reports of autoantibodies of anti-e specificity, there has been at most a single bona fide case.

On page 154, the authors again repeat the myth of the six Rh antigens C, D, E, c, d, and e. Moreover, they write, "Wiener considers that there are 8 alleles at a single locus so that the antigens . . . are determined in threes by a single gene." This is incorrect, since the myth of triple inheritance also was originated by C-D-E adherents. Wiener maintains instead that Rh agglutinogens are each characterized by multiple blood factors, ranging up to 10 factors for certain agglutinogens at the present stage of knowledge, and increasing as new Rh-Hr antibodies are found. The authors also assert that there are in use three different notations for the Rh-Hr types, namely, the C-D-E notations, the Rh-Hr notations, and "the so-called clinical notations much used in Great Britain." However, the so-called clinical or shorthand notations are nothing more than an adaptation of Wiener's Rh-Hr nomenclature, so that there are actually two, not three, nomenclatures in use. Thus, the objection to the Rh-Hr nomenclature being too difficult to understand implies that Wiener's Rh-Hr notations become more understandable only after they are renamed "clinical or shorthand notations."

In view of these faults the book regrettably cannot be recommended to beginners, because it is far more difficult to unlearn incorrect teaching than it is to learn a subject correctly in the first place. Fortunately there are more reliable books available at the present time, with whose aid beginners can readily orient themselves in this complex but important subject.

Clinical Chemistry in Practical Medicine. By C. P. Stewart, D.Sc., Ph.D., Reader in Clinical Chemistry, University of Edinburgh, Edinburgh, and D. M. Dunlop, B.A., M.D., F.R.C.P., Christison Professor of Therapeutics and Clinical Medicine, University of Edinburgh. Fifth edition. Cloth. $6.75. Pp. 342, with 30 illustrations. E. & S. Livingstone, Ltd., 16 and 17 Teviot Place, Edinburgh 1, Scotland; [Williams & Wilkins Company, 428 E. Preston St., Baltimore 2], 1958.

The number of editions this short English textbook has gone through suggests that it is a useful book to at least some members of the medical profession. As the title indicates, it is a synopsis of laboratory examinations in clinical medicine. A chapter is devoted to each subdivision (e. g., cerebrospinal fluid and hepatic function), and each chapter consists of a short discussion of basic physiology, followed by a list of the more important tests and the principal changes encountered in disease. The material presented is accurate and up to date, and it is well and simply written, an almost universal virtue of English textbooks. The only defect of this book is its brevity; it is too synoptic. Too much has been left out, and what is presented is given in too short a manner to make it effective. For example, 14 pages are devoted to the basal metabolic rate. Three or four sentences are given to protein-bound iodine (PBI), and the subject is then dismissed with the remark that it is not suitable for routine work. In listing the causes of low glucose concentration in the spinal fluid, no mention is made of diffuse meningeal carcinomatosis. In the chapter on hormone abnormalities almost nothing is said of normal or pathological blood and urine values for the hydroxycorticosteroids, although three pages are given to the 17-ketosteroids. This book is not suitable for medical students or for physicians who want a thorough knowledge of the subject. It will certainly be useful to students of biology and biochemistry and will probably prove satisfactory for candidates for professional examinations who want a quick review of a very important subject.

Occupational Allergy: Lectures Held During a Course on Occupational Allergy at The Hague in May, 1958, Organized by the Netherlands Society of Allergy in Co-operation with the Netherlands Institute for Preventive Medicine and the Netherlands Society of Occupational Medicine Under the Auspices of the European Academy of Allergy. Cloth. $10. Pp. 329, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; H. E. Stenfert Kroese N. V., Leiden, Netherlands, 1958.

About 40 authors, including allergists, internists, pediatricians, rhinologists, and dermatologists, among others, contributed to this volume. Essentially, the book discusses various allergic manifestations produced by occupational duties, methods of allergic examination, diseases and their causes in the various professions and industries, therapy, prophylaxis, and socioeconomic aspects. Among the occupations discussed are those of wool textile workers, bakers, printers, nurses, wood workers, cement workers, miners, and employees in pharmaceutical industries. While the material is informative and may be helpful to European physicians, it is inadequate for the American physician, who is faced with problems involving plastic, petroleum, rubber, and all the complexities of a variety of chemical industries. The book lacks organization, as shown by an unevenness in the different contributions as to the factual material, form of presentation, and form of references (presence or absence of references, with or without titles, last name or first name first, full name or initials, and many errors in the spelling of names). Despite imperfections this volume can serve as a supplement to a library on occupational allergy.

Handbook of Histopathological Technique (Including Museum Technique). By C. F. A. Culling, F.I.M.L.T., F.R.M.S., Chief Technician, Westminster School of Medicine, University of London, London. With foreword by R. J. V. Pulvertaft, O.B.E., M.D., F.R.C.P. Cloth. $9; 45 shillings. Pp. 446; 27, with 80 illustrations. Butterworth & Co., Ltd., 88 Kingsway, London, W. C. 2, England; 1367 Danforth Ave., Toronto 6, Canada, 1957.

To write a handbook of histopathological technique is a difficult undertaking, in this time of rapid advances. The author has composed a remarkably inclusive book based on his many years of extensive experience in this field. The work is devoted essentially to the fundamentals of histopathological technique, and the author does not attempt to cover many of the procedures involved in histochemistry. Of particular importance, and not covered in other existing works of this kind, is a section on museum technique. Another section deals with the microscope and various aspects of microscopy, including fluorescent microscopy, polarizing microscopy, and phase-contrast microscopy. The author has produced an excellent coverage of the fundamentals of histopathological technique. His emphasis on fundamentals, with the purposeful exclusion of many techniques in histochemistry, has added to the value of this work, which should prove extremely helpful to the student.

Problems of Addiction and Habituation. Edited by Paul H. Hoch, M.D., and Joseph Zubin, Ph.D. Proceedings of forty-seventh annual meeting of the American Psychopathological Association, held in New York, February, 1957. Cloth. $6.50. Pp. 250, with 12 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England. 1958.

This book consists of 15 articles and 2 discussions by various authors. Most of the articles review work already published elsewhere. The subjects of various articles cover a wide range, from the development of experimental neuroses in animals to the factors relative to social and psychiatric management of addiction in the United States. Tiebout makes an eloquent plea for direct treatment of the symptom of alcoholism; Masserman attempts to review an enormous mass of work on the effects of drugs on various forms of behavior in animals; Speer defends the use of severely repressive legal measures in the management of narcotic addiction; while Bowman favors a permissive system for the management of addiction in the United States, similar to the plan developed by the New York Academy of Medicine. As might be expected, the quality of the various articles is uneven. The book should be of most value to persons working with the problem of alcoholism or drug addiction.

QUESTIONS AND ANSWERS

ESTROGENS AND CLOTTING

To the Editor:—*If estrogens are given intravenously to control hemorrhage by quickly increasing the concentration of prothrombin and accelerator globin, is it not reasonable to expect similar action, to a lesser degree, when they are taken orally? If this is so, would there not be a greater possibility of arterial occlusion, particularly coronary, among the rank and file of women who are taking estrogens?*

M.D., California.

Answer.—The changes observed in the blood components that promote coagulation accompany the intravenous injection of relatively large amounts of the conjugated estrogens. This rapid increase in the estrogens seems to be essential. The continued oral administration, with slower gastrointestinal absorption, apparently does not have the same effect. Ancillary changes in capillary integrity, circulating lipids, and other elements involved in coagulation accompanying estrogen administration possibly protect the vascular system from the increased coagulability of the blood. Such an "explanation" for the lack of vascular disease in women taking estrogens is at present without complete experimental foundation. It is, however, known that purified components of the conjugated estrogens do not give rise to the same changes in coagulation components or to as great a degree if change does occur.

OPTIMUM HUMIDITY

To the Editor:—*What range of humidity is considered best for skin and mucous membranes? Has air-conditioning been known to reduce humidity to the point of inducing dermal or mucosal irritation?*

James H. Lade, M.D., Albany, N. Y.

Answer.—There are not sufficient scientific data at present to determine the humidity which is best for the skin and mucous membranes. Excessively low humidity, 20% or lower, causes drying of the skin and mucosa with decreased activity of the cilia lining the upper respiratory tract. Excessively high humidity may give an uncomfortable sensation and in warm weather interferes with heat loss. In cold weather any type of heating system or air-conditioning without accompanying humidification may give a low humidity, but any irritation of the skin and mucosa would be due entirely to the drying effect. In warm weather low humidity is not likely to occur with air-conditioning because dehumidification is expensive.

FUEL OIL DERMATITIS AND SEQUELAE

To the Editor:—*A 35-year-old pregnant woman, finding her basement floor flooded with fuel oil which had escaped from the tank, removed her hose and shoes and waded across the floor to turn off the valve and then proceeded, still barefoot, to clean up the basement. During the night she developed a massive macular eruption on her feet and ankles which was pruritic and burning. The next morning she discovered that she was unable to void, and she did not void until catheterization was done in the mid-morning. The urine at that time was almost milky in color and contained a few red blood cells, much mucus, many casts, and many leukocytes. After this she voided with difficulty because of tenesmus and dysuria which persisted until medication, which had been prescribed, became effective within 24 hours. Six days later she began to develop lower abdominal cramps which she said were like mild labor pains. In 48 hours she began to show some spotty uterine bleeding, and at the end of five days she had an abortion of an 8-week-old fetus. It is thought that the dermatitis was due to contact with the fuel oil and assumed that the urinary symptoms were due to the absorption or inhalation of some of the hydrocarbons in the fuel oil. May it be said that the abortion was also due to the toxic effects of the fuel oil?*

L. Mason Lyons, M.D., Terre Haute, Ind.

Answer.—In general, it can be said that there are no components of fuel oil which will cause all of the pathological changes observed in this patient. The occurrence of dermatitis after contact with fuel oil and its specific localization to the exposed portions of the body is rather conclusive evidence that some constituent of the fuel oil was the etiological agent, although two factors—the "massive macular eruption" and its appearance almost immediately after exposure—are not characteristic

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

of the usual dermatitides due to fuel oil. The patient's symptoms and urinary findings present a confused picture: the tenesmus, dysuria, mucus, and cellular elements indicate a cystitis, whereas the many casts show some renal involvement. The milky color of the urine requires more data for explanation, and no information is given regarding a febrile reaction or the presence of systemic symptoms. An abortion occurred one to two weeks after exposure and supposedly after all the dermal and urinary manifestations had subsided. No other associated systemic symptoms are given. Apparently this patient had no signs or symptoms referable to the central nervous, respiratory, or gastrointestinal systems, and some would certainly be expected if there had been inhalation of a volatile material or absorption through the skin of almost any known toxin. The components of fuel oil are not known to cause any of the pathological changes in the urinary or genital tract which occurred in this patient, nor is there any additive or solvent which would produce them. Therefore, while it seems more than likely that the dermatitis was due to the fuel oil, the rest of the patient's difficulties cannot be explained on the same basis and it is not clear why they occurred.

SIDE ACHE

To the Editor:—*What is the cause of the pain commonly experienced in the flank or upper part of the abdomen during strenuous exercise or rapid walking? An 18-year-old boy is unable to play basketball because of pain in the upper part of the abdomen which occurs only during exertion and which is relieved promptly by rest. Studies, including electrocardiogram, complete gastrointestinal series, and sickle cell preparations, all give negative findings. What treatment is recommended?*

M.D., Kentucky.

Answer.—The differential diagnosis of stabbing pains in the chest was considered by Langley (*Ann. West. Med. & Surg.* 6:49, 1952). He listed a number of conditions in the thoracic viscera, thoracic wall, vertebral column, and abdominal viscera and mentioned the common "stitch in the side" or "side ache" about which many young people complain when running. He ascribed it to "strain of an intercostal muscle," but this explanation is given without evidence. Observations on 114 attacks of side ache in 55 persons were reported by Capps (*J. A. M. A.* **116**:2431 [May 24] 1941). The important features were found to be a constant relation to exertion, a tendency for the ache to occur after eating, a variable location, usually in either the right or the left upper quadrant of the abdomen, relief by bending over or from local pressure, and a tendency to aggravation in cold weather. Previously proposed theories regarding the mechanism of pain are untenable. Anoxemia of the diaphragmatic muscle for the side ache is the explanation offered. Why the pain is unilateral is not clear. Perhaps the person stops exercising before the other side begins to hurt. Improved breathing might well put less of a load on the diaphragm. There are theoretical reasons for supposing that recently introduced muscle-relaxant drugs might reduce the tendency of the diaphragm and intercostal muscles to go into spasms and that one or another of the many vasodilators now available might prevent ischemic contractions of these muscles. As yet, however, no studies along these lines have appeared.

INFECTIOUS HEPATITIS AND PREGNANCY

To the Editor:—*Are pregnant women less susceptible to infectious hepatitis than the rest of the population? Is this disease more benign in pregnant as compared to nonpregnant women? If pregnant women are not less susceptible to infectious hepatitis, should they receive gamma globulin for their own protection and for the protection of the fetus?*

Bertrand M. Bell, M.D., Donaldson, S. C.

Answer.—There is no evidence that pregnant women are less susceptible to infectious hepatitis than the rest of the population. Pregnancy places a greater strain on the liver, and infectious hepatitis in pregnancy is more dangerous not only for the mother but also for the fetus. If pregnant women are exposed to infectious hepatitis, gamma globulin should be given for protection of both mother and fetus. An intramuscular injection of about 0.02 ml. per pound of body weight would be suitable.

BLOOD SUGAR DETERMINATIONS

To the Editor:—*A newly employed, well-trained, registered technician has insisted on the use of what is called the dextrose-kit method of performing the blood sugar test. He maintains that this is as accurate as the older Folin-Wu method. Is he right?*

M.D., Alabama.

Answer.—The answer to this problem depends to a certain extent on which dextrose-kit method is used. There are several so-called dextrose-kit methods in which no colorimeter is required. The final color in the blood test is compared with color standards until a match is obtained. For example, one such test is based on the ferricyanide method of Folin. Color standards are set up in milligrams per 100 cc., and the results are accurate within about 10 mg. per 100 cc. of blood. Another method is based on the reduction of copper sulfate (Folin). The resulting color is matched against a color scale with 50-mg. intervals. The colors are much like those produced with Benedict's solution when used to test the urine for sugar. With this method, there is a wide range in the accuracy of the reading. With any of these tests, no appreciable time is saved as compared with the standard blood sugar methods with use of a regular colorimeter. With all these methods, the blood needs to be precipitated and filtered. The filtrate, when mixed with the appropriate chemicals, is boiled for a given period. Consequently, no appreciable time is saved. Any physician who employs a medical technician should use a standard method with a regular colorimeter to obtain an accurate blood sugar level reading.

KOILONYCHIA

To THE EDITOR:—*What is the treatment of koilonychia which has developed spontaneously in a 63-year-old woman? She first developed spooning of her fingernails two years ago, and it has progressed to involve all of the fingernails and has begun to involve the toenails as well. She has taken gelatin faithfully for over a year without any effect. Even though she was not anemic iron was given by mouth, without benefit. In the hope of producing some favorable effect, one physician prescribed large doses of the vitamins A, B, and C, as well as calcium tablets. These agents were given for three months, and no improvement was noted. The patient's basal metabolic rate and plasma cholesterol level are normal. Are any systemic diseases known to be associated with this condition?*

M.D., Ohio.

ANSWER.—Koilonychia still remains a real therapeutic problem in many instances. It may affect several fingers or all fingers at the same time, though very rarely. While it is common in some families, in others it occurs individually. It has been found to coexist with lichen planus, occasionally with other rare skin diseases, in extreme cachexia, and, rarely, with syphilis. On the other hand, it is often difficult, if not impossible, to determine the etiological agent. Several observers, such as Cipollaro, believe that many of these are occupational in origin, i. e., that they result from handling strong acids and alkalies, but others have not found this to be an important factor. A few cases have been associated with dystrophy of the hair and plantar and palmar hyperkeratoses. In some of these patients, vitamins A and D and calcium have been of help. In a few patients there has been an achlorhydric anemia which responded to appropriate iron medication, but there appears to be no such connection in the case in question. In this instance, apparently no cutaneous or internal abnormalities have been found. It would be justifiable to use vitamin D and calcium salts, the latter in the form of calcium gluconate given intramuscularly.

HYPERSENSITIVE DENTIN

To THE EDITOR:—*About a year ago, information was obtained for the treatment of hypersensitive dentin. This included use of ammoniated silver nitrate, followed by 1 drop of eugenol, and brushing the teeth with hot mineral oil, Andresen's paste, sodium silicofluoride, or Thermodent tooth paste. A sodium fluoride-kaolin-glycerin mixture and stannous fluoride were not recommended because they might cause degeneration of the dental pulp. Is any other treatment recommended?* *M.D., West Virginia.*

ANSWER.—All methods named have their enthusiastic proponents, but controlled clinical studies to support them are generally lacking. The sodium fluoride-kaolin-glycerin mixture has been adequately tested and shown to be an effective desensitizer. It can be used safely because damage to pulp results only when sodium fluoride is used in freshly cut cavities and, therefore, does not apply to desensitizing applications. Except for the fact that stannous fluoride and silver nitrate may stain teeth, they are perfectly safe. Desensitizing agents will not prevent recurrence of sensitivity if erosion is continuing and exposing fresh, sensitive dentin. Treatment should include correction of factors causing erosion or gingival caries. Andresen's paste, which is a mixture of phosphates and other salts, for daily application, is supposed to do this, but the evidence is unconvincing.

PHENOL FOR RHEUMATISM

To THE EDITOR:—*Many people in this area use phenol as a sort of home remedy in the treatment of rheumatism, arthritis, and allied diseases. The usual dose is one drop, diluted with water, taken three times a day. Good results are claimed. Would this be safe over a prolonged period?*

M.D., Missouri.

ANSWER.—There appears to be no therapeutic rationale for the administration by mouth of phenol in any form of arthritis. This consultant would advise against it.

"AIR PLATES" AND CONTROL OF HOSPITAL INFECTIONS

To THE EDITOR:—*A more satisfying answer to the question on "air plates" and control of hospital infections, published in* THE JOURNAL, *Dec. 27, 1958, page 2329, can be found by perusal of the book by Wells (Airborne Contagion and Air Hygiene, Cambridge, Mass., Harvard University Press, 1955). Briefly, a 15-minute exposure of a Petri dish represents the number of particles settling out on 1 sq. ft. per minute (rate of deposit). Volume air samplers collect the total number of bacteria in a given volume (bacterial* *density). Settling velocity is the quotient. A high settling velocity (greater than 1) indicates dustborne bacteria and a low velocity, droplet nuclei (less than 4 ft. per minute). Room air has a settling velocity of 1 or 2 ft. per minute, indicating the preponderance of dustborne organisms. Settling velocities can be used to differentiate airborne from dustborne contagion.*

AEROPHAGIA

To the Editor:—*In* The Journal, *Nov. 22, 1958, page 1734, in answer to a question on aerophagia the consultant suggested eating with the mouth closed as a preventive measure. While it is true that this may help, much of the swallowed air enters the esophagus through the nose rather than the mouth. To prevent this, some form of nasal pinchers, such as those used in underwater training of lifeguards, would be helpful, or small cotton pledgets moistened with water might be placed in each nostril. Charcoal is of doubtful value because a very large quantity would be required to absorb all the air in the stomach. Furthermore, charcoal loses its ability to absorb gases when it is wet.*

G. Franco Capuani, M.D.
Bal. Lamarmora, 15
Novara, Italy.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*It will rarely be necessary for persons with aerophagia to use pinchers or pledgets of moist cotton to close their nose when swallowing. This would be quite impractical, if not impossible. Furthermore, when the nose is closed, a person takes in air through his mouth. It is not clear just how charcoal works in a situation like this. From our clinical experience, however, it definitely reduces the amount of intestinal gas and it has been thought to do so by absorption. Many persons get striking relief from gaseous dyspepsia by this simple procedure.*

URIC ACID AND PREECLAMPSIA

To the Editor:—*In regard to the question on uric acid and preeclampsia, which appeared in* The Journal, *Feb. 14, 1959, page 777, it may be relevant to point out that chlorothiazide may raise the serum uric acid level (Laragh and others,* J. A. M. A. 166:*145-152 [Jan. 11] 1958; Oren and others,* J. A. M. A. 168:*2128-2129 [Dec. 20] 1958). Chlorothiazide is often given to patients with toxemia of pregnancy. Currently, at Cook County Hospital, work being done on this subject seems to indicate that when chlorothiazide is given in doses of 0.5 Gm. twice daily a slight increase in the serum uric acid level occurs in pregnant patients with and without toxemia. Perhaps the inquiring physician used larger doses. The hyperuricemic effect of chlorothiazide may be important if one relies on the uric acid level for prognosis or treatment.*

BLOOD PRESSURE DETERMINATION AND VALVULAR DISEASE OF THE HEART

To the Editor:—*In the Jan. 10, 1959, issue of* The Journal, *page 202, a question appeared concerning the "sea gull murmur," described as a high-pitched systolic murmur; the consultant indicated this is a "high-pitched, screeching systolic murmur maximal near the cardiac apex." The information which is available to me on this subject is somewhat at variance with these opinions. According to Groom and Boone (*Ann. Int. Med. *42:1214, 1955), the sea gull murmur, also known as the "dove-coo" murmur, is a unique musical murmur, decrescendo in character, prolonged through most of diastole, and generally maximal in the mid-precordium. The consultant indicated that most of these murmurs have been shown to be associated with eversion or retroversion of an aortic valve cusp, usually from syphilitic aortitis.*

George X. Trimble, M.D.
Seaside Memorial Hospital
1401 Chestnut Ave.
Long Beach, Calif.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*The comment relative to the sea gull murmur is appropriate if it is based on the article by Groom and Boone, because in that article the sea gull murmur is described as synonymous with the dove-coo murmur. This consultant knows of no authoritative source to indicate that a sea gull murmur has specific diagnostic value. By common usage it has come to mean a high-pitched, musical, screeching murmur, and most of these are systolic in time, in contrast to a similar musical murmur, diastolic in time, which may be specifically related to aortic insufficiency. This seems to be a matter of semantics which does not have a firm traditional foundation.*

TRANSFUSION REACTIONS AND THEIR TREATMENT, ESPECIALLY WITH THE ARTIFICIAL KIDNEY

Gurbuz M. Barlas, M.D.
and
Willem J. Kolff, M.D., Cleveland

Transfusions of incompatible blood caused severe reactions in 16 patients; 13 cases are described. The usual course consisted of three successive periods referred to as the acute, the oliguric, and the diuretic phases. In the acute phase many of the characteristic symptoms may be masked by anesthesia; watchfulness is therefore necessary, and recognition of symptoms has to be followed at once by cessation of the transfusion and treatment for shock. In the oliguric phase it was necessary to be on guard against overhydration, edema, hypertension, hyperpotassemia, acidosis, uremia, and infection (especially bronchopneumonia). Twelve of the patients in this series were treated with an artificial kidney and nine recovered. In six of them recovery would have been very difficult or impossible without the hemodialysis.

MUCH has been written about unusual causes for transfusion reactions—allergies,[1] pyrogens,[2] and rare blood groups[3]—but there is an understandable reluctance to write about the most common cause of trouble, simple incompatibility or mismatching of blood. Still, transfusion of incompatible blood is the cause of most so-called transfusion reactions; its occurrence is not rare. This paper outlines the treatment and reports our experiences, especially with dialysis, in the treatment of the acute renal failure that follows transfusion of incompatible blood.

Clinical Phases After a Transfusion Accident

It is convenient to consider three phases in acute renal failure: (1) acute reaction, (2) oliguric phase, and (3) diuretic phase.

Acute Reaction Phase.—Symptoms and signs of acute transfusion reactions can be listed as follows, but it should be remembered that anesthesia masks most of the symptoms: chill followed by fever, pain in the lumbar region, flushing of the face or cyanosis, substernal pain, headache, anxiety, nausea and vomiting, cough, rapid and shallow breathing, and distention of neck veins.

There may be symptoms of shock: hypotension, tachycardia, collapse, or prostration. Hemoglobinemia can be found if a blood sample is drawn and centrifuged within an hour or two after the accident. Jaundice usually follows and becomes evident in 3 to 24 hours. Hemoglobinuria can be

found at the early stage; it disappears within 24 hours when urinary suppression follows. During an operation (when anesthesia masks most symptoms), the most prominent sign may be bleeding from cut surfaces.

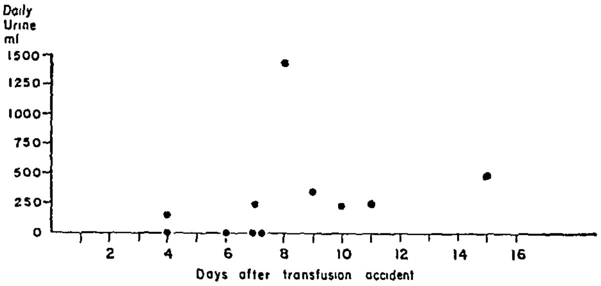

Fig. 1.—Days of oliguria prior to first dialysis and amount of urinary output during 24 hours preceding dialysis.

Oliguric Phase.—The urinary suppression leads to development of uremia. The clinical course greatly depends on the medical management of the patient during this phase. Overhydration leads to peripheral and pulmonary edema and hypertension. Hypertension may lead to convulsions. Even with optimum medical management, accumulation of retention products occurs, leading to mental changes, drowsiness, stupor, psychosis, or coma. Sudden death may occur even in the absence of potassium intoxication. The presence of serious injury, infection, ischemia, or necrosis of muscle precipitates rapid clinical deterioration (and requires early and frequent dialysis).

Diuretic Phase.—The beginning of the diuretic phase is arbitrarily chosen as the time when the urinary output reaches 1,500 ml. in 24 hours. The beginning of diuresis does not end the danger to the patient. Until sufficient tubular function has returned, a high urinary output does not guarantee adequate elimination of nitrogenous waste products or exclude electrolyte imbalance resulting from renal losses. Infections (resistant staphylococcus) and hypertension may still develop.

Acute Phase

Emergency Measures.—On the occurrence of any of the acute signs and symptoms listed above, transfusion should be discontinued immediately. The needle should remain in place for immediate treatment of shock if it develops. Intravenously given fluids, dextran, or compatible blood may be given. Arterenol may be required in addition.

To establish the diagnosis, the physician himself should draw blood from the patient, spin it for hemolysis, and have it cross-matched before his eyes with blood from the incriminated bottle. He should refuse to accept any previously used samples, to exclude the possibility of clerical error.

Specific Treatment.—Intravenous administration of a 5% solution of dextrose in water (2 liters) with 300 mEq. of sodium bicarbonate should be given immediately. This solution is designed to prevent blocking of the renal tubules with acid heme. This measure seems to be beneficial, but only when carried out immediately. It is harmful when renal shutdown has already been established.

Mannitol, 50 or 100 ml. of a 25% solution, may be administered in the hope of increasing urinary flow by osmotic diuresis. This perhaps is useful if given immediately.

Exsanguinotransfusion, according to French authors,[4] should be considered for reduction of free hemoglobin in the blood plasma. Only during the first hours after onset of hemolysis will the free hemoglobin in the plasma be effectively removed.

Oliguric Phase

Maintenance of Body Fluid.—During the oliguric phase insensible loss of water is replaced with at most 500 ml. of fluid per day. Fluid lost by vomiting, diarrhea, abdominal drainage, and whatever small volume of urine is excreted may also be replaced.[5] Even if this fluid restriction is adhered to, gradual overhydration takes place through the catabolism of tissue with release or formation of water. Water in food plus water of oxidation is at least equal to the weight of the diet consumed. Daily body weights are important. As long as the patient is able to take fluids by mouth, he should not be given fluid intravenously except perhaps as

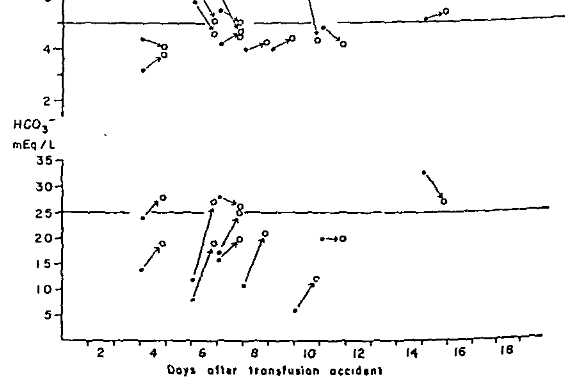

Fig. 2.—*Top,* serum Na^+ and K^+ levels, *bottom,* HCO_3^- level before and after dialysis. Each arrow indicates change of electrolyte level during dialysis.

a vehicle for hypertonic dextrose or fructose. Intravenous infusions in patients with acute anuria carry the risk of acute pulmonary edema or convulsions.

If, during the oliguric phase, overhydration occurs with its dreaded sequelae of cardiac decompensation, hypertension, pulmonary edema, or convulsions, venesection is the most effective immediate remedy for an increased blood volume. During venesection, blood pressure must be measured since the withdrawal of 300 to 500 ml. of blood may be sufficient.

Removal of Edema Fluid.—Sodium sulfate, 45 Gm. in warm water taken by mouth, will retain 1,500 ml. of fluid to make an isotonic solution of 3.2% in the gastrointestinal tract and will cause diarrhea; it is of doubtful value. Peritoneal lavage can remove fluid from the patient if a 3 to 10% dextrose solution is added to the usual composition of the dialyzing fluid. It was not used in this series of patients. The most effective way to remove edema fluid is by ultrafiltration with the artificial kidney. Too rapid loss of large amounts of ultrafiltrate sometimes is followed by mental confusion, but removal of 4 liters per dialysis is possible. The resultant improvement of pulmonary edema is dramatic.

Hyperpotassemia.—Hyperpotassemia is often seen during the oliguric phase. Recognition of hyperpotassemia is best accomplished by determining the serum potassium content with the flame photometer. The electrocardiogram with its very high T waves, broadened QS complexes and low P waves is only a poor substitute for the direct determination. There are several ways of treating hyperpotassemia:[5] 1. Absorption of K+ may be achieved with cation exchange resins (Na+ salt or hydrogen cycle of carboxylic resin or sodium polystyrene sulfonate) in the intestinal tract; 40 to 60 Gm. may be given orally in divided doses or 60 Gm. by repeated high retention enemas.[5] 2. An emergency cocktail may be given intravenously: 10, or 20, or 40% solution of dextrose or invert sugar (40% solution of invert sugar is given into the vena cava), 1 liter; calcium gluconate, 6 to 10 Gm.; sodium lactate, 180 mEq.; and insulin, 20 or 40 units. Thus, effects of K+ on the heart muscle may be postponed until an artificial kidney takes over. 3. Rapid digitalization may be performed. 4. Dialysis with the artificial kidney is the most certain and effective way to reduce any degree of hyperpotassemia within an hour.

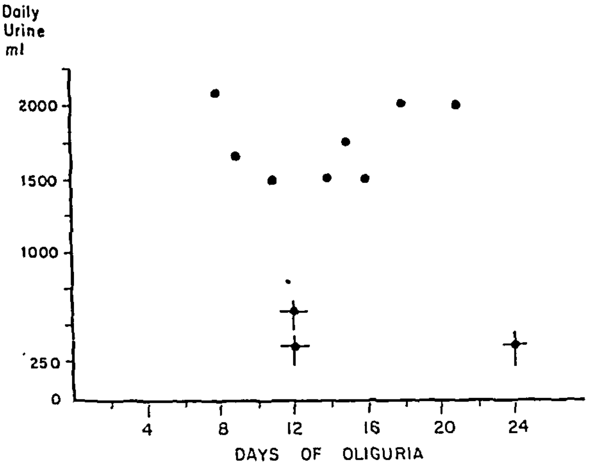

Fig. 3.—Durations of oliguria before beginning of diuresis (urinary output of less than 1,500 ml.): range 8 to 22 days.

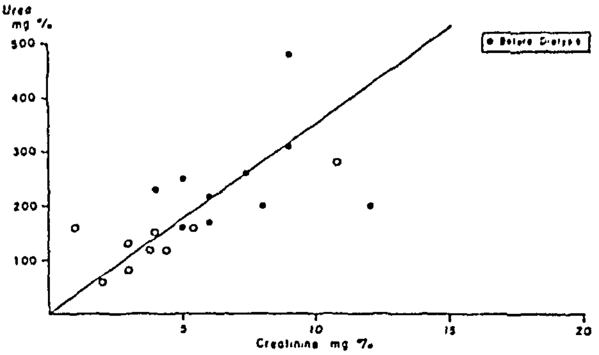

Fig. 4.—Correlation between blood urea and creatinine levels in 11 patients before dialysis (dot indicates values before first dialysis, open circle after dialysis).

Hypocalcemia.—Hypocalcemia is frequent in patients with acute renal failure. It seldom causes symptoms. Convulsions only occasionally are due to hypocalcemia. Tetany usually disappears after intravenous administration of 1 Gm. of calcium gluconate; painful leg cramps sometimes disappear.

Acidosis.—During the oliguric phase acidosis practically always occurs. Carbohydrate is administered to reduce starvation ketosis. If the alkali reserve is lower than 12 mEq. per liter, administration of 40 mEq. of sodium lactate or sodium bicarbonate per day may have to be considered. The sodium salt of carboxylic resin given because of hyperpotassemia is effective in relieving acidosis.

Dialysis provides the most effective means of correcting acidosis. The metabolic acids that have accumulated in the blood are removed and normal constituents, Cl^- and HCO_3^-, are replaced.

Suppression of Protein Catabolism.—We administer a regimen low in protein and as high in calories as is practical for suppression of protein catabolism.[6]

Transfusion.—Only when the hemoglobin concentration is lower than 8 Gm. per 100 ml. should the administration of fresh concentrated red cells be considered. It carries the risk of augmenting the blood volume; with the slightest sign of overloading of the circulation or pulmonary congestion, an equal amount of the patient's blood should be withdrawn. Attempts to raise the hemoglobin concentration to normal will only cause increased blood destruction (1 liter of blood contains 70 Gm. of protein).

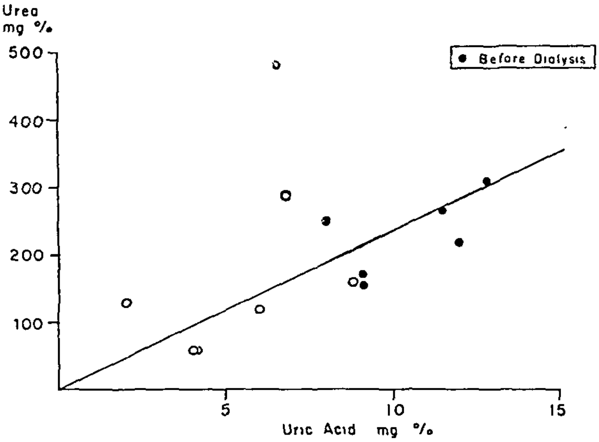

Fig. 5.—Correlation between blood uric acid and urea levels in 11 patients before dialysis.

Prophylaxis and Treatment of Infection with Antibiotics.—Antibiotics often are needed for control of the underlying disease; they should be given prophylactically before pneumonic complications develop in the respiratory tract during a period of stupor or coma. Erythromycin, 2 Gm. on the first day and 1 Gm. daily on the following days, may be administered. Streptomycin, on the other hand, is dangerous because of possible vestibular damage; its administration should not be continued for longer than three days in the presence of anuria.

Artificial Kidneys.—Artificial kidneys were used when the methods described above seemed insufficient to bring about recovery. Disposable twin-coil kidneys were used.[7] Each coil contains two cellulose tubes, 10 meters long. Dialyzing surface for the twin coil is 18,000 sq. cm. The patient is treated with the artificial kidney for a period of six hours. The electrolyte composition of the dialyzing solution resembles that of blood plasma.[8] It takes 1,100 to 1,400 ml. of blood to prime one twin-coil kidney. Dialysis may have to be repeated in three to six days.

Results of Present Study

Between 1954 and 1958, 16 patients having received incompatible blood were seen. The blood was administered for a variety of reasons. Six patients received blood during and after operations, and two received blood because of hemorrhage after delivery. The amount of blood transfused ranged from 1 to 7 pints. A man who received 7 pints of incompatible blood recovered.

The 12 seriously ill patients were treated with dialysis, and 3 of the 12 died. The other four patients recovered without dialysis.

In three patients the transfusion accident happened in large hospitals; two of them did not develop oliguria because the reactions were diagnosed early and the transfusions were discontinued. Thirteen patients were transferred from small hospitals; all were in the oliguric phase.

Three patients had received Rh-incompatible blood: one immediately after delivery and two two and one-half and four years, respectively, after delivery of an erythroblastotic baby. The other patients received simply incompatible blood. For example, a patient with a blood group O received group A. In no case did the trouble result from the use of O donor blood.

Dialysis was performed during the oliguric phase. Only once was it performed in a patient whose urinary output exceeded 500 ml. per 24 hours. Two patients received dialysis as early as the 4th day, and one patient had his first dialysis as late as the 15th day after the accident (fig. 1). The dialyses corrected the serum Na+, K+, and HCO_3^- levels toward normal (fig. 2). In spite of the

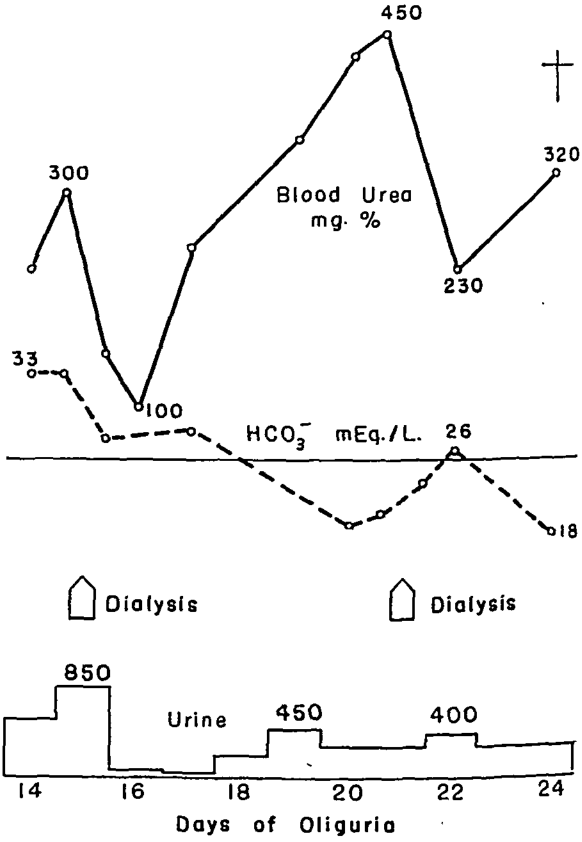

Fig. 6 (case 2).—Predialysis and postdialysis data in critically ill patient with oliguria.

rinsing fluid Na^+ level of 132 to 138 mEq. per liter, the serum Na^+ level after dialysis was often 140 mEq. or more. With one exception, the serum sodium and serum potassium levels were corrected toward normal; the exception was not significant. During dialysis, imbalances of HCO_3^- were corrected toward toward normal. The periods before onset of diuresis ranged from 8 to 22 days (fig. 3).

The elevation of the blood urea level usually parelleled that of uric acid and creatinine levels. In only 2 of 10 patients in whom both were determined was there no parallel between blood urea and blood creatinine levels (fig. 4). On one occasion the blood urea content was high (480 mg.%) with a relatively low blood creatinine content (9 mg.%), which reflects the relatively short duration (six days) of oliguria. In one patient with a blood urea content of only 200 mg.%, the blood creatinine content was high (12 mg.%), in spite of a short duration of oliguria (three days). These findings suggested preexisting renal disease, of which there was no evidence. After dialysis, since both urea and creatinine had been removed according to their gradients, a good correlation between the two was found in all determinations.

There was a good correlation between uric acid and urea levels (fig. 5) in all except one patient. Since dialysis removes retention products according to their gradients, the heights of blood urea, creatinine, and uric acid levels were parallel in all patients after treatment with the artificial kidney.

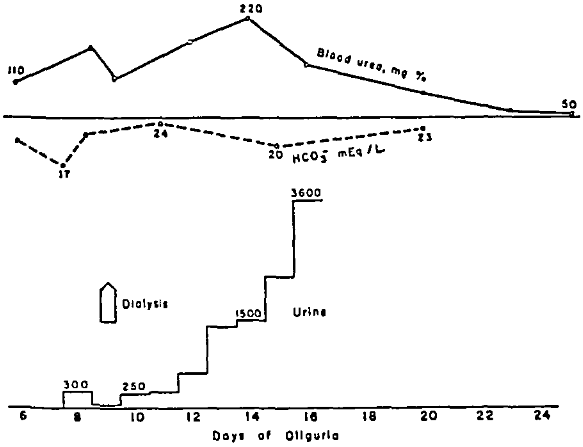

Fig. 7 (case 4).—Data in patient given dialysis.

Report of Cases

Following is a brief review of the cases of 13 patients who developed oliguria after incompatible blood transfusion. At least six patients (cases 1, 4, 5, 8, 9, and 12) would probably not have survived without dialysis. (In the figures accompanying these case reports, the straight line indicates the approximately normal value for blood urea [50 mg.%, high normal], blood creatinine [1 mg.%], serum HCO_3^- [25 mEq. per liter], serum Na^+ [140 mEq. per liter], and serum K^+ [5 mEq. per liter]. Each treatment with the artificial kidney is indicated by a pointed column.)

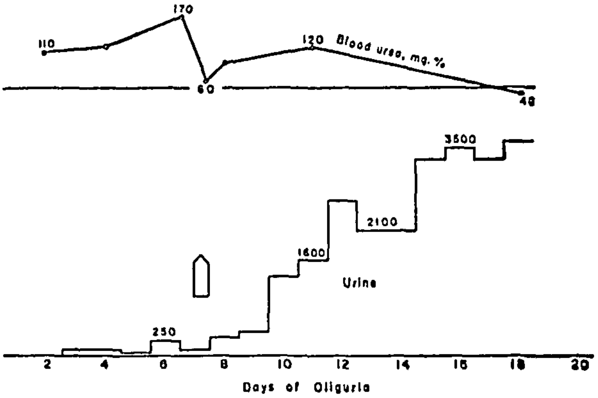

Fig. 8 (case 7).—Data before and after dialysis in patient with low blood urea content and high blood creatinine content.

CASE 1.—A 13-year-old boy was given dialysis at the onset of the diuretic phase because his clinical condition was deteriorating. He recovered.[8]

CASE 2.—A 58-year-old woman was admitted to Cleveland Clinic on the 14th day of oliguria. She had received incompatible blood in transfusion during cholecystectomy and repair of an inguinal hernia. Oliguria, fever, vomiting, and rectal bleeding developed. When she was admitted to our hospital two weeks later, she was unconscious and had general twitching and tremor. She was given dialysis twice. During the second dialysis, complete heart block developed. The blood pressure dropped despite our attempts to maintain it with blood transfusion, mephentermine, and dextran. Her condition deteriorated (fig. 6), and she died on the 24th day of oliguria. Autopsy revealed tubular necrosis and bronchopneumonia; the latter finding explains the continued deterioration.

The fall in blood pressure during the first dialysis may have contributed to the decrease of urinary output after dialysis which far exceeded the usual decrease after dialysis. A fall in blood pressure cannot always be avoided in patients as critically ill as this one was. Every effort should be made to avoid bronchopneumonia.

CASE 3.—A 33-year-old woman had received a blood transfusion during hysterectomy. On the fourth day of oliguria she was given dialysis. She had an uneventful course, with diuresis beginning on the 10th day.

CASE 4.—A 30-year-old woman had a perineal abscess and received incompatible blood in transfusion during an anal fistulectomy. On the next day she passed a small amount of bloody urine. She was admitted here on the sixth day of oliguria. On the ninth day she was given dialysis. Diuresis started on the 15th day. She had an uneventful hospital course after dialysis and was discharged in good condition (fig. 7).

This case illustrates the importance of performing dialysis before the patient's clinical condition deteriorates.

Case 5.—A 40-year-old woman received blood during a major operation and was admitted here on the 10th day of oliguria. She was given dialysis immediately and a second time on the 13th day of oliguria. Diuresis began on the 18th day.[9]

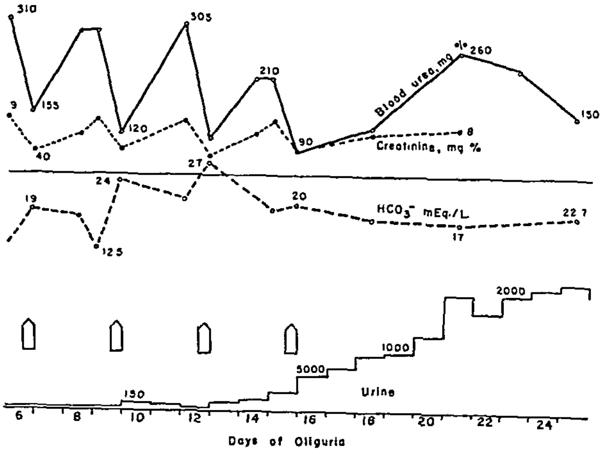

Fig. 9 (case 8).—Results of dialysis in patient who had been given 7 pints of incompatible blood.

Case 6.—A 22-year-old woman recovered from oliguria without dialysis. The potassium level was controlled with resins. Diuresis began on the 13th day.

Case 7.—A 28-year-old woman gave birth two weeks before admission to a baby with Rh-positive blood (the baby had an exchange transfusion). After delivery, because of hemorrhage, she had uterine curettage. She was given a transfusion with Rh-incompatible blood and developed oliguria. On the sixth day of oliguria she was given dialysis. She improved during the next days and was discharged in good condition (fig. 8).

This is an example of a patient with a relatively low blood urea content (125 mg.%) and a relatively high blood creatinine content (15 mg.%).

Case 8.—A 46-year-old man had a nephrectomy. He developed postoperative bleeding, and operation was again performed on the next day, when he received 7 pints of incompatible blood. Severe oliguria and rapid deterioration of his clinical condition developed. He had four treatments with the artificial kidney and recovered (fig. 9). Five months later he was found to be in excellent health.

This was our first experience with a patient who recovered in spite of having been given such a large amount of incompatible blood. We believe that the favorable outcome was due to early dialysis.

Case 9.—A 26-year-old woman was given 2 pints of incompatible blood for metrorrhagia. Acute renal failure with jaundice, nausea, vomiting, and oliguria developed. On the second day of oliguria she was transferred here. Her condition deteriorated, and dialysis was done on the fourth day of oliguria; improvement followed.

A second dialysis was done on the ninth day of oliguria. During her hospital course, potassium-binding resins were given to keep the serum potassium content within limits (fig. 10). She was discharged after a uterine curettage and has completely recovered.

This case is presented as an example of early dialysis indicated by a serious clinical condition that could not be adequately explained by elevation of levels of the usually determined retention products.

Case 10.—A 28-year-old woman developed oliguria after receiving Rh-incompatible blood after a hysterectomy. She was given dialysis on the seventh day of anuria. She recovered.

Case 11.—A 36-year-old woman had given birth to an erythroblastotic baby two and one-half years previously. She received two units of blood after a uterine curettage in a small hospital. Fever, backache, oliguria, and vomiting developed.

On the sixth day of oliguria she was admitted here, acutely ill with a blood urea content of 480 mg. per 100 ml., serum K^+ content of 6.5 mEq. per liter, and serum HCO_3-content of 12 mEq. per liter (fig. 11). She was given dialysis on admission, and her condition improved. Because of rapid, subsequent deterioration she was given dialysis a second time on the 10th day of oliguria. The next day fever developed. A third dialysis was planned for the 15th day. Tracheotomy was done. During the cut-down procedure for the dialysis she died in cardiac arrest due to potassium intoxication. Autopsy showed tubular necrosis.

Case 12.—A 61-year-old woman received a transfusion for anemia. Transfusion reaction was noted and the transfusion was stopped, but it was restarted by another person when symptoms subsided. She was given dialysis twice and recovered.

Case 13.—A 50-year-old woman was admitted to the hospital on the 11th day after hysterectomy and transfusion; she was given dialysis. She died three days later without having improved. Autopsy showed peritonitis and fatty degeneration of the liver.

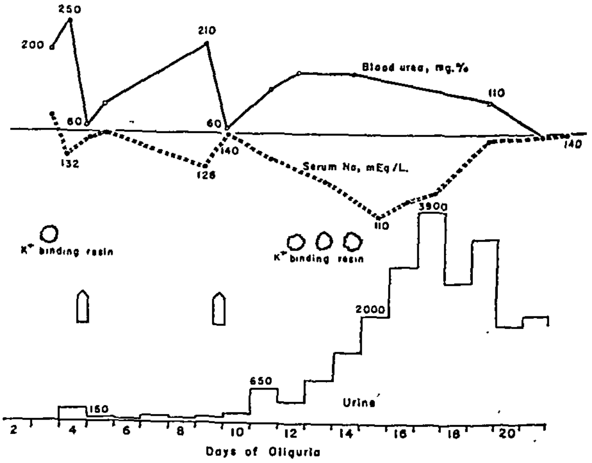

Fig. 10 (case 9).—Results of dialysis in patient with serious clinical condition not explained by elevated levels of retention products.

Comment

Although 13 of our 16 patients were transferred from small hospitals, this means not that transfusion reactions occur less frequently in large hospitals but only that fewer patients were transferred from large hospitals. In the small hospitals the accidents often resulted from mismatching, whereas the three cases in large hospitals resulted from clerical errors. For some patients information concerning the accident was inadequate. Three of the 16 patients died. If two of them had been brought to our hospital earlier, they would have had a chance for recovery or at least for better management. The third patient died from cardiac arrest while preparations for a third dialysis were being made; we failed to anticipate a rapid rise in the serum potassium level. In several of the patients indications for a transfusion were doubtful. The presently prevailing risk of blood transfusion should be more clearly realized.

Indications for treatment of oliguric uremia with the artificial kidney as they developed during the course of this work are as follows: 1. Chemical indications. The blood urea level is higher than 200 mg.%, serum K+ level approaches 7 mEq. per liter, and serum HCO_3^- level is lower than 12 mEq. per liter. The urea content may be out of line with determinations of levels of other retention products, such as creatinine and uric acid. 2. Clinical indications. The patient is stuporous, comatose, or so drowsy that he does not cooperate and does not cough properly. He may be wild, disoriented, or unmanageable. The need for ultrafiltration is indicated by pulmonary edema, hypertension, and convulsions.

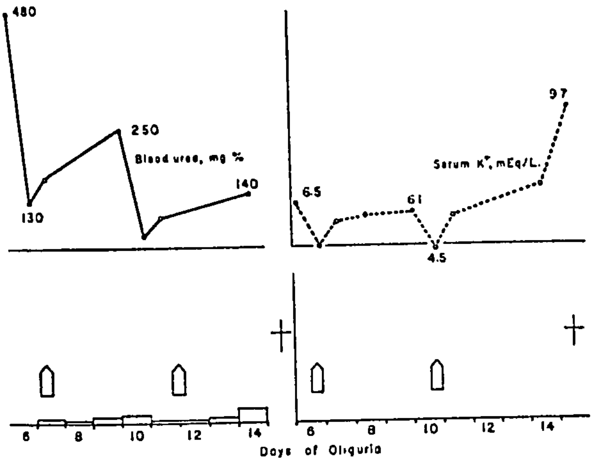

Fig. 11 (case 11).—Cardiac arrest after unanticipated rise in serum potassium level.

An incompatible transfusion is a terrible accident. It becomes a tragedy if the patient is not properly handled. Treatment is best given in a medical center where the staff has experience in the complete management of these cases and where there are facilities for dialysis.

Summary

Between 1954 and 1958, 16 patients in renal failure after transfusions with incompatible blood were treated. Four patients were treated conservatively, and they recovered. Twelve patients were treated with the artificial kidney; nine recovered, and three died. Two of the three patients who died should have been transferred to our center earlier, and one should have received her third dialysis earlier. Disposable twin-coil kidneys were used.

A rise in levels of blood urea and other retention products occurs. In most cases a linear correlation between blood urea, creatinine, and uric acid levels existed, but not always. The medical management of patients with anuria-oliguria includes restriction of fluid intake and prohibition of sodium intake. K+-binding resins lower the serum potassium level, and their sodium salt also tends to correct acidosis. Protein catabolism is discouraged by a high-calorie, low-protein regimen. Prophylactic antibiotic treatment is indicated. Indications for the artificial kidney are chemical (blood urea level greater than 200 mg.%, serum K+ level 7 mEq. per liter, and serum HCO_3^- level lower than 12 mEq. per liter) and clinical (stupor, coma, disorientation, and restlessness). Need for ultrafiltration is indicated by pulmonary edema, hypertension, and convulsions.

2020 E. 93rd St. (6) (Dr. Kolff).

This study was supported by a grant from the Life Insurance Medical Research Fund.

The twin-coil kidneys used in this study were supplied by Travenol Laboratories, Morton Grove, Ill.

TELEVISION IN OTOLARYNGOLOGY AND OTHER SPECIALTIES—A NEW TEACHING DEVICE

Paul Moore, Ph.D.
and
Hans von Leden, M.D., Chicago

Clinical teaching is difficult when conditions do not permit more than one person at a time to see the part of the body that is being examined or treated. The equipment here described is designed to overcome this difficulty. It is mounted on the instructor's head in such a way as to permit him to observe the interior of an organ directly while a properly aligned and focused television camera picks up an image that can be transmitted to an audience of any desired size. The critical elements of the apparatus are a small, lightweight television camera and a periscopic system with front-surfaced mirror, peep-sight, lens, and prism. The helmet bearing the apparatus is heavy and must be counterpoised. External sources of intense illumination are available. This form of closed-circuit television is useful in clinics, classrooms, operating rooms, and situations arising in postgraduate instruction.

Clinical teaching in otorhinolaryngology has been handicapped by the inability of the examiner to expose the cavities of the ears, nose, and throat for simultaneous inspection by others. The narrow channels of the head that transmit sound outward from the organ of voice and inward to the organs of hearing can be visualized readily only by one person at a time. Similar difficulties beset the gynecologist and proctologist as well as the endoscopist in the fields of urology, otolaryngology, chest surgery, and gastroenterology.

This limitation of observation presents a serious handicap to clinical, classroom, and surgical instruction. Two procedures are currently in general use to alleviate this problem; both have been helpful in selected instances, but neither satisfies the primary need. One of these techniques requires the placement of a small mirror near the viewing axis of the examiner in such a position that the critical image is reflected to a second observer. The second procedure referred to is photography, including both still and motion pictures. The mirror method displays the clinical material immediately, but the observation is sometimes difficult to accomplish and is limited to one additional viewer at a time. Photography, on the other hand, displays the material to many observers but the immediacy of the clinical presentation is lacking.

It is obvious that a procedure which allows an examiner or surgeon to show a specific area deep in a body cavity to any desired number of observers at the moment of examination or treatment provides a greatly improved method of teaching. The accomplishment of this objective depends on the satisfaction of three basic requirements: the examiner must be able to see the field clearly, the equipment must conform to the examiner's movements, and all other observers must be able to visualize the same area as the examiner. It is evident that the third requirement could be met with closed-circuit television, provided the image is received simultaneously by a television camera. This procedure has been demonstrated in general medicine and surgery where standard lighting and camera techniques are applicable. However, when the critical field of observation lies within a restricted channel, the direct view of the television camera is obscured during the process of examination. The fundamental requirement, therefore, for simultaneous viewing and televiewing of the cavities of the head and neck is a positioning of the equipment which allows the camera to receive an image in the optical axis of the examiner. At the same time this arrangement must preserve a direct view of the field and retain freedom of movement for any manipulation. We have developed a practical pilot model of a television-scope that meets these three requirements.

It is evident from the schematic illustration of the equipment (fig. 1) that the mechanism rests on the examiner's head and that the camera gathers its picture by means of a periscopic lens. The light reflected from the subject (fig. 1*A*) travels directly to the eye of the examiner and, at the same time, to the television camera by way of a mirror and lens arrangement (fig. 1*B*, *D*, and *E*). The periscopic system and the camera support provide the necessary mobility for both the examiner and the camera and permit coaxial viewing and televiewing. The details of the components in this combined unit are presented under the three functional divisions which compose it: the optical and television system, the supporting mechanism, and the illumination.

From the Laryngeal Research Laboratory, William and Harriet Gould Foundation, and Northwestern University Medical School.

Optical and Television System

The small, lightweight television camera and the periscopic lens are the critical elements of the present equipment. The optical system is composed of five important elements that will be described in their functional sequence: front-surfaced mirror, peep-sight, lens, prism, and vidicon tube.

Front-Surfaced Mirror.—The front-surfaced mirror (fig. 1*B*) is so constructed and located that it reflects the image upward to the camera lens yet allows the same image to pass through to the eye of the examiner. The cut-away section of the illustration shows the mirror resting in the observer's line of sight at an angle of 45 degrees to the viewing axis. The separation of the image beam may be accomplished by two different types of mirror. In one form the surface is sparsely coated with a reflecting material; in the other the glass is densely covered except for a small clear area in the center. With the partial mirror, the surface is uniform but a reduced amount of light is reflected to the lens, since some light "leaks" through over the entire area. The other, or center-hole, mirror reflects all of the light except at the small central area where the light passes through the clear glass. Both kinds of mirror have been used in this development, but the center aperture type was adopted because it reflects the image with less loss of light and presents a brighter field to the observer. The center opening is not evident in the television image because it is out of the focal range, and the intensity is not noticeably affected as long as relatively large lens apertures are used.

Peep-Sight.—The peep-sight is composed of a pair of holes 3/32 in. in diameter placed 1½ in. apart. These openings are located at the inner and outer ends of the rearward extension of the mirror housing (fig. 1*C*). The size of the holes and their placement enable the examiner to see fields of 1½-in. diameter when the subject-to-mirror distance is 12 in., of approxmately 2 in. at a distance of 15 in., and of 2½ in. at 18 in. These sighted areas coincide with the field covered by the television camera lens and aid the examiner in aiming the camera precisely at the field of interest. This restriction of the field through the peep-sight does not pose any problem for the examiner since his other eye retains full view of the entire field of vision.

Lens.—The lens (fig. 1*D*) used in the present instrument is a modified 6-in. f/4.5 Tessar lens with the elements permanently focused at a subject distance of 20 in. The barrel containing the lens elements is continuous with the mirror housing below and the prism holder above. This unit con-

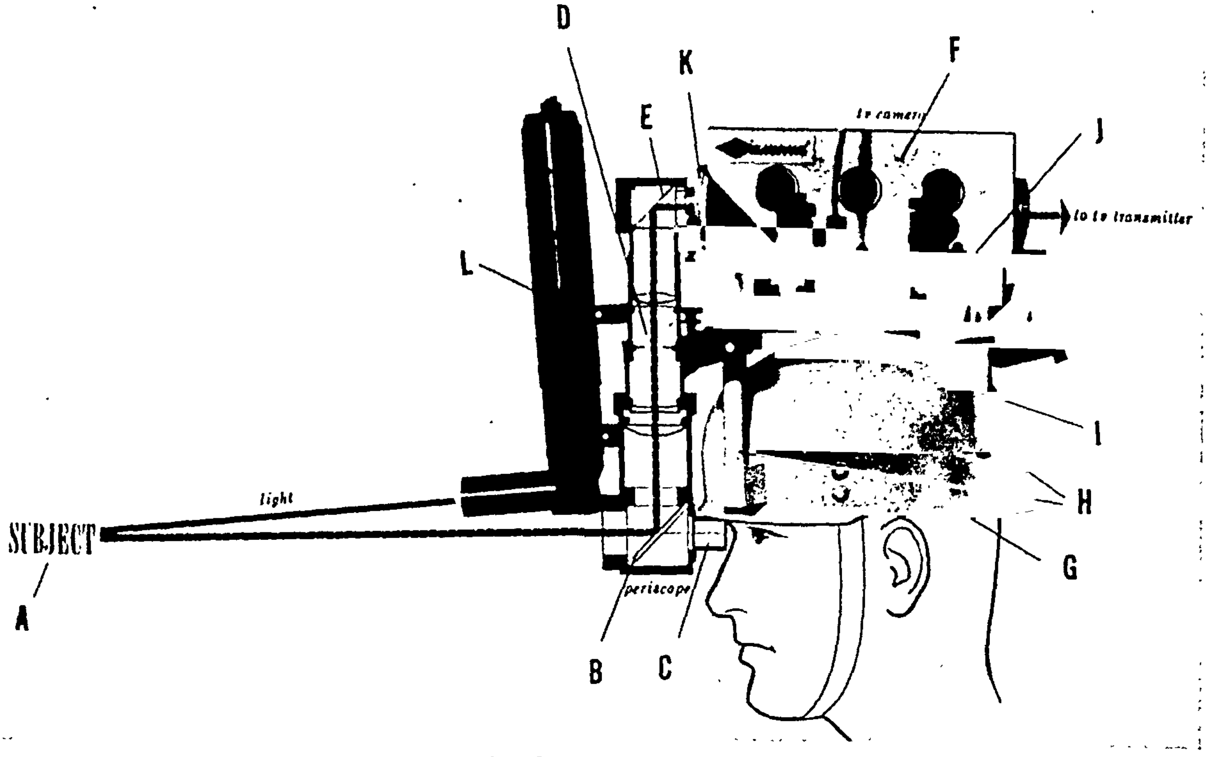

Fig. 1.—Photodiagram of television-scope.

struction maintains a constant eye-level to camera-level distance and adds a desirable rigidity to the assembly. The fixation of the lens elements eliminates the customary type of optical focusing and permits substitution of adjustment at the focal plane, which is described later in the discussion of the vidicon tube.

Prism.—After the image beam traverses the lens elements it is turned 90 degrees toward the television camera by a 1-in. prism that is mounted at the top of the lens section (fig. 1*E*). The housing which supports the prism opens toward the camera and is attached to the supporting structure of the helmet by means of a threaded collar and thumbscrews.

Vidicon Tube.—The final stage in the optical system is the television camera (fig. 1*F*); here the light is focused on the vidicon tube where the visible image is converted to electrical impulses that travel by way of a multiconductor electrical cable to the control equipment and subsequently to one or more television screens.

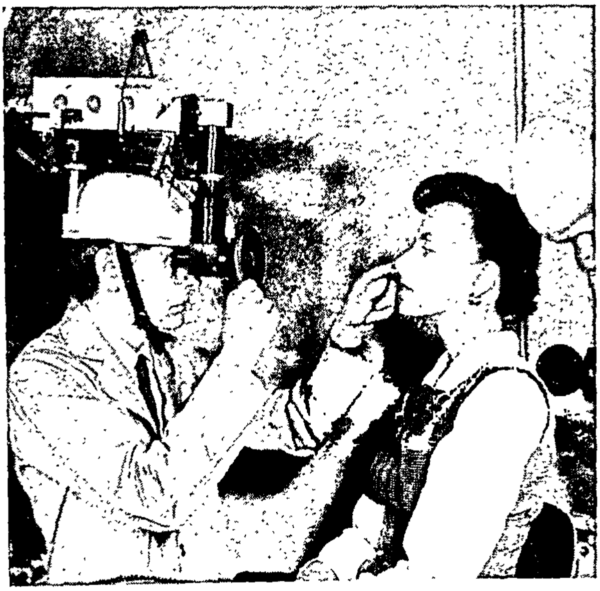

Fig. 2.—Nasal examination demonstrating illumination by means of modified head mirror and detached light source.

There are two systems for obtaining an optical focus of an image on a vidicon tube that may be used with the present equipment: in one type the lens is adjusted while the tube remains stationary; in the other, the lens is fixed and the tube is moved toward or away from the lens. The second method was selected as the more desirable for this pilot model because it is simpler and lends itself to either manual adjustment or remote electrical control.

Supporting Mechanism

The successful application of this periscopic television system to teaching in otorhinolaryngology and other surgical specialties depends to a large extent on the ease and simplicity with which the mechanism can be manipulated. The equipment that supports the operating part must be comfortable, mobile, noninterfering, and adaptable to different persons and situations. The mechanism that supports the television camera and its associated components is composed of two primary parts: the equipment worn on the examiner's head and the counterweighting system that carries the helmet and attached units.

Head Unit.—The basic structure of the unit worn on the head is a Fiberglas helmet (fig. 1*G*) to which four metal tubes 4¼ in. long are attached at equally spaced intervals as indicated by the illustration (fig. 1*H*). At the top of the tubes an aluminum plate (fig. 1*I*), 8⅝ by 10⅛ in., is fastened securely to give rigidity and stability to the foundation structure. The four tubes are fitted with free-sliding rods that are attached at their upper ends to a second aluminum plate (fig. 1*J*) that forms a platform for the television camera. The rods are fastened by pin-and-eye hinge joints that permit the upper platform to be tilted and lifted in relation to the lower plate. These adjustments between the platform and plate compensate for variations in vertical head dimensions among different examiners. The peep-sight must be raised or lowered to accommodate the eye level of the examiner, an adjustment which is accomplished by a corresponding positioning of the camera platform. A simple system of levers connects the two plates at their corners and applies the force that varies the interplate angle and distance; thumb screws lock the levers in their desired positions.

On the upper surface of the platform two auxiliary aluminum plates are mounted for the support and adjustment of the camera. The smaller of the plates, 8⅝ by 5⅛ in., is attached to the underside of the camera and slides toward and away from the lens; this movement accomplishes the focusing mentioned above. The second of the auxiliary plates, 8⅝ by 6⅛ in., holds the sliding camera plate, supports the lens system on the vertical plate (fig. 1*K*), and positions the entire optical-camera system laterally. This side-to-side adjustment combined with the front-to-back and vertical motions described earlier provides a universally adjustable camera support on the examiner's head.

Counterweighting System.—The weight of the equipment attached to the helmet is approximately 18 lb., too much to be carried comfortably without some external assistance. A simple and flexible supporting mechanism was devised consisting of a counterweighted bar resting horizontally on an adjustable vertical shaft. The bar is joined to the upright shaft by means of a ball-bearing bracket that permits the bar to swing around the shaft and provides a fulcrum for vertical movement. A T-shaped unit that suspends the helmet is adjustable along the bar and thereby provides the means of establishing equilibrium. A balanced suspension is the most comfortable and flexible adjustment for the use of this equipment.

Illumination

Two methods of illumination have been used interchangeably with the present pilot model: in one, light from an external source is reflected onto the subject by a modified concave head mirror (fig. 2); in the other method, a beam from a small, high candle power lamp attached to the periscope lens (fig. 1*L*) is directed to the critical area. The reflected light system was developed to simulate the method of illumination used traditionally in the field of otorhinolaryngology. This system offers almost limitless intensity of illumination, since the independent light source can be as powerful as desired. It also provides shadow-free lighting as the result of the beam converging from all points around the lens axis. The principal disadvantage of the reflected light technique is the need for adjustment of the mirror each time either the examiner or the subject moves. When both hands are occupied in an examination or operation, the coincident positioning of the camera and illumination is difficult to manage.

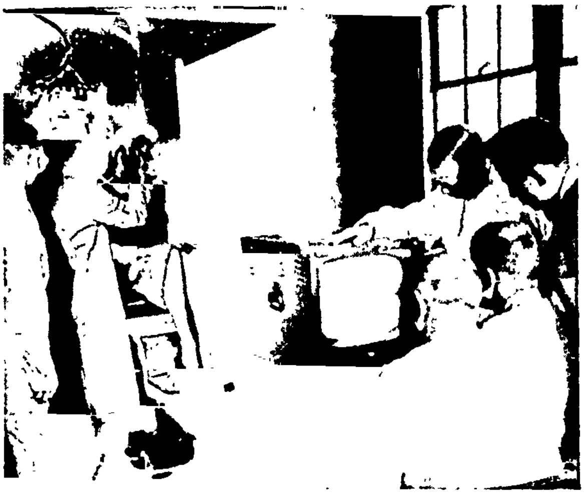

Fig. 3.—Study of tympanic membrane of patient, by means of television monitor, while physician conducts his examination.

This problem of mirror adjustment led to the development of the alternate method of lighting in which a lamp and appropriate lenses are mounted on the optical lens assembly. In this system the camera field and the lighted area are made congruent and secured in this relationship. Consequently, the lens field is always illuminated, which relieves both of the examiner's hands for patient management. The two limitations of the integral lamp in the pilot model are light intensity and parallax factors associated with the positioning of the lamp. Both of these limitations are relatively simple technical problems which are being solved in current development of the equipment.

Applications

We believe there are four teaching situations in which the new type of television equipment, described above, will be particularly useful. The first three, clinic, classroom, and operating room, are illustrated in figures 3, 4, and 5.

Figure 3 shows a group of medical students in an otology clinic studying the tympanic membrane of a patient by means of the television monitor while the otologist conducts his examination. Figure 4 pictures a class of nurses receiving instruction on the functioning of the larynx; and figure 5 demonstrates the equipment in the operating room during operations on the nose and ear. The fourth type of instructional application is an extension of the other three into postgraduate teaching. Closed-circuit television provides the method for disseminating new techniques and information to the physician in his home, office, or hospital. This form of instruction has been used in several branches of medicine, but, with new equipment, this teaching procedure can be extended to otolaryngology and other surgical specialties dealing with deeply placed structures.

Further Developments

The experimental application of the pilot model to various teaching situations has demonstrated that a television camera and associated periscopic lens system supported on the head of an examiner provides a practical means of improving clinical instruction. The developmental program has also revealed several desirable changes in the equipment that should be incorporated in its further refinement. These may be summarized briefly, for the convenience of those contemplating similar developments, into four specific and somewhat interrelated modifications: increase in the depth

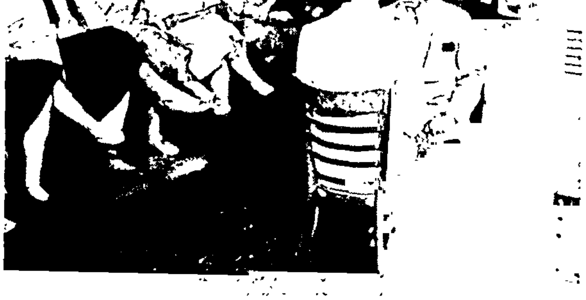

Fig. 4.—Class viewing action of larynx by means of television screens during examination.

of the televised field, variation of field size, modification of the helmet support attachment, and introduction of color television.

Increase of Depth of Field and Variation of Field Size.—In the pilot model the single, fixed, telephoto lens provides maximum magnification of the image at the cost of a shallow field and a relatively small subject area. For teaching purposes it would be ideal if all structures present in the television image could be presented in sharp focus and if the area surveyed by the lens could be made larger and smaller to fit the organ or cavity being examined. Available equipment makes it possible to approach these goals through the selective balancing of such factors as various focal length lenses, size of lens aperture, illumination, and improved television equipment. The pilot model has been redesigned to accept these modifications through provisions for interchangeability of lenses, increased illumination, and a more sensitive television camera tube.

Modification of Helmet Support Attachment.—The suspension of the helmet and associated equipment shown in figure 1 is designed primarily for horizontal viewing. The present range of motion is entirely satisfactory for the usual clinical and classroom demonstrations, but during surgical procedures increased vertical variation is desirable. This maneuverability may be accomplished by attaching the suspension brackets on either side of the helmet at the level of the lower plate, which is close to the axis of vertical rotation and permits easy downward motion of the camera.

Color Television. — The greatest improvement which could be made would be conversion from black and white to color television. The use of color helps to delineate the natural features of the areas being visualized and suggests the three-dimensional character of the field. These features are particularly important in the areas under discussion, where all structures display variations of one and the same color. We hope a small color camera will be developed soon which can be adapted to this televiewing system.

Summary

In the past, clinical teaching in otorhinolaryngology and other surgical specialties has been limited by the difficulty of displaying critical areas within the ear, nose, throat, and other body cavities for student observation. The basic problem has been solved with a small television camera and an associated special periscopic lens system. The device permits direct viewing by an examiner and simultaneous televiewing by others of exactly the same subject area. A complete working pilot model was built and used in several teaching situations in otorhinolaryngology. This application of the instrument demonstrated its practicability and revealed a few desirable modifications that are being instituted in continuing development. With appropriate changes in the optical system, the same principle could be applied to television of similar procedures in various branches of medicine and surgery.

HEART EXAMINATION AND CONSULTATION BY RADIO AND RADIO-PHOTO TRANSMISSION

Arthur Briskier, M.D., New York

The transatlantic sending of heart sounds, roentgenograms, and other essential clinical data is possible. The accuracy of such transmission from New York has been tested by recording the data on tape in Paris and Rome and instantly retransmitting to New York. There was no language barrier when the transmitted records contained no spoken words. The transmitted information, both visible and audible, was received in the form of recordings that could be examined with deliberation and stored for reference. The experiments here reported were concerned with heart conditions, but the possibilities so revealed were far-reaching.

In this age of space travel, when each moment counts, it is important that medical consultations with an appropriate specialist be available at any time and place, particularly in cases of emergency. The best clinical examination, of course, results from personal contact with the patient, and it is the doctor who should make the diagnosis, not the machine. It is not the purpose of the described method to substitute heart auscultation by radio-electronic devices for such examinations, but in emergencies, or when the patient is at a great distance from the specialist, the application of the modern means of communication will undoubtedly prove beneficial.

The radio transmits information of all kinds instantly from one corner of the earth to the other and telephotography similarly transmits photographs. These modern technical facilities are available to medicine. The heart, being the motor of any living body, deserves particular consideration; indeed, my first essays in distance transmissions were records of heart examinations. The first two experiments with transatlantic transmissions of heart auscultation were performed on May 26 and July 3, 1958, from New York to Paris and Rome.

Transmissions

First, the details of auscultation of a normal heart were transmitted through sound tape.[1] In Paris and Rome a recording was made of the transmitted heartbeats. In order to check cardiac acoustic phenomena received abroad, the recorded sounds were instantly retransmitted from Paris and Rome back to New York. It was thus possible to judge the quality of the transmission and the reception through retransmission of the audiovisual records.[2] Within a few seconds the heart sounds crossed the ocean twice, first to Europe and then back to America.

With the heart sounds a visual record was transmitted by radiophotography, containing the clinical data on the patient such as age, sex, height, weight, temperature, and blood pressure as well as a chest roentgenogram, an electrocardiogram, and the symbolic cardio-charting.[3] The transmitted records also contained the results of laboratory tests.

After the successful reception of the audiovisual data on a normal heart, records of certain pathological cases were transmitted, including instances of mitral stenosis, mitral insufficiency, aortic stenosis, and aortic insufficiency. Preoperative and postoperative data on cases of cardiac surgery were then transmitted, including tight mitral stenosis, mitral stenosis with subacute bacterial endocarditis, patent ductus arteriosus with subacute bacterial endocartitis, and tetralogy of Fallot. It would not have been possible to compare at a distance the auscultatory findings preceding and following surgical intervention without the recorded preoperative auscultatory details.

After the surgical records, fetal heartbeats which had been recorded just before delivery were also transmitted along with the normal heartbeats of the mother for purposes of comparison. Audiovisual transmission of cardiac records which are often sufficient can be supplemented if necessary in special cases by direct transoceanic conversations between two medical consultants.

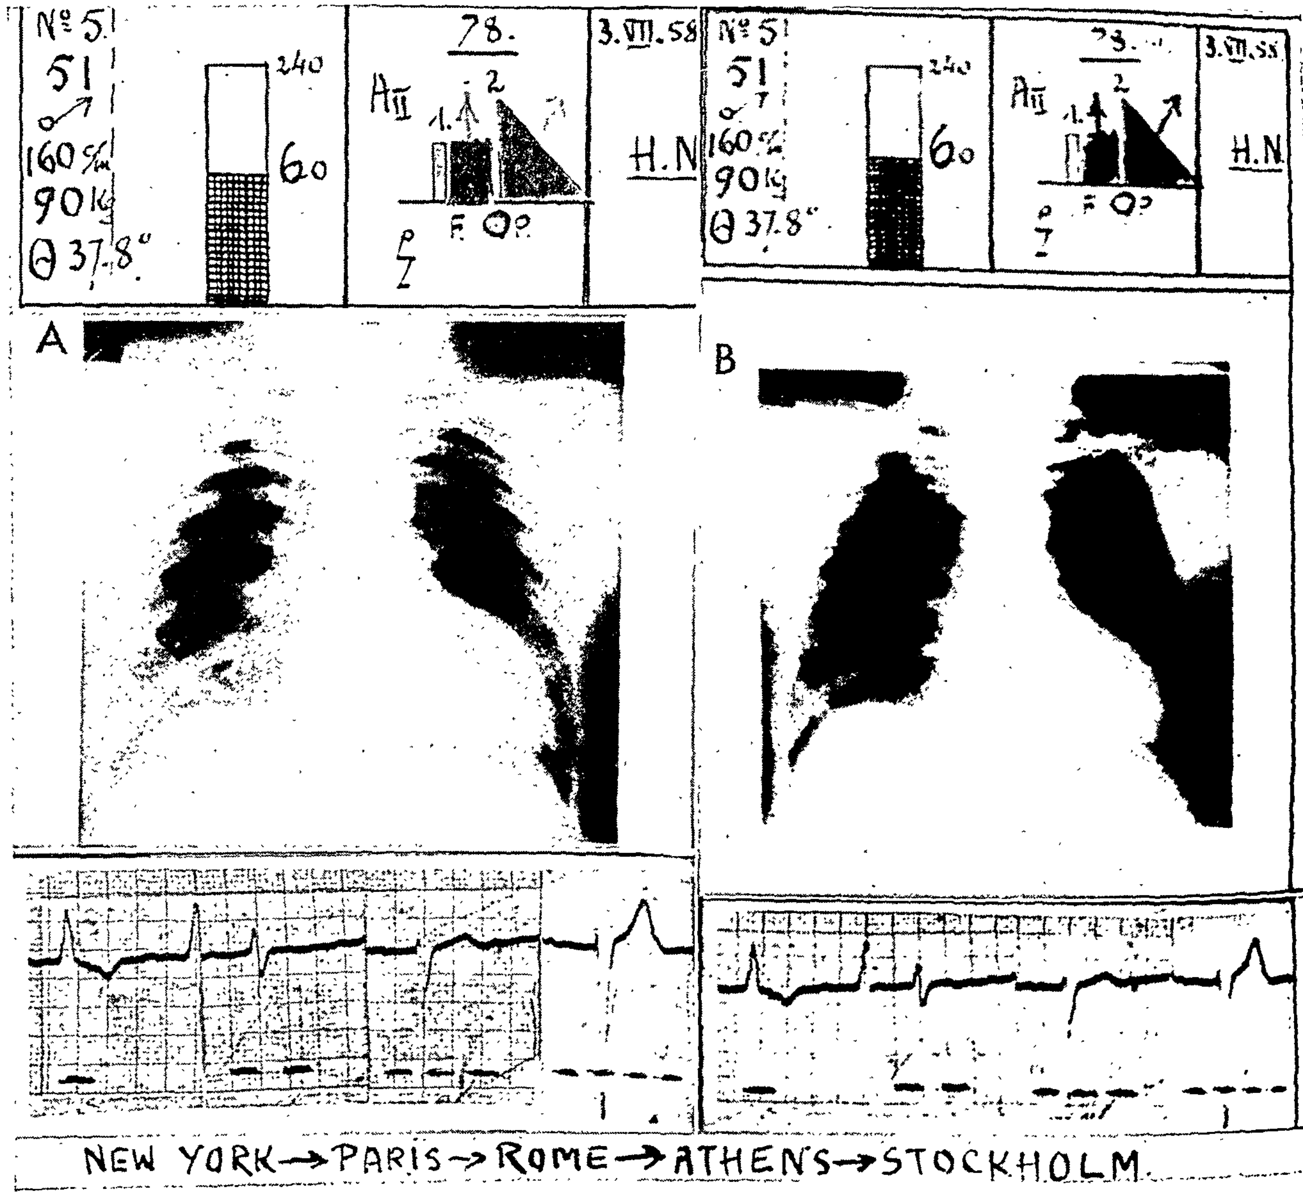
Technique

Cardiac auscultation is first recorded on sound tape[4] through an appropriate microphone and then played back for audible transmission. The recording speed is irrelevant since cardiac frequencies are rather low. While the speed of transmission may or may not correspond to the recording speed, the playback must be at the recording speed. The auscultation can also be directly transmitted, if the cardiac sounds and murmurs are fed directly from the patient's chest through the microphone and the magnetic head to the transmitting instrument.

The visual record, which contains the clinical data, the chest roentgenogram, the electrocardiogram, and the cardio-chart,[5] is located on one side of a sheet of paper which is placed on the drum of the telephoto transmitter. The photograph received in Europe is similar to the original transmitted from New York, and can be used at once for medical interpretation (see figure).

Results.—Abroad, the reactions of the heart specialists to the transmitted records were similar to the reactions these same examiners would have had during an actual examination of the same patients. While the audiovisual record is studied at the point of reception, a copy is transmitted so that patients can be instantly studied, discussed, and compared in the remotest parts of the world by the appropriate specialists while the patients themselves remain undisturbed.

sion of laboratory tests, and communication of therapeutic results; and instant reporting of medical data concerning epidemics and disasters. Although the experiments reported here were concerned exclusively with heart conditions, this method of consultation by radio transmission will prove useful in all fields of medicine, surgery, and obstetrics.



A, visual record transmitted from New York; B, same record a few minutes later at reception in Paris, indicating age, sex, height, weight, temperature, pulse, cardio-chart, chest x-ray, and electrocardiogram. Cardio-chart (top) shows (1) first heart sound; (2) second heart sound masked, following (1) loud rough systolic murmur radiating upward, following (2) soft decrescendo murmur radiating outward and upward best heard at A_{II} aortic region, second interspace.

Applications.—This method has such far-reaching applications as cardiac consultation with specialists located anywhere in the world, particularly when the desired specialist is on a different continent than the patient; in cases of emergency, lifesaving consultations from a plane, a boat, the desert, or the jungle; teaching, demonstration of unusual medicosurgical cases, communication of scientific discoveries; establishment of diagnosis, transmis-

Universality.—The transmitted records contained no spoken words, so there were no language barriers. Because of the simplicity and the clarity of the records, including the self-explanatory symbolic cardio-charting, the messages are instantly understood by all physicians of any nationality.[6] The method is therefore universal in scope and spirit.

Thanks to radio and radiophotographic transmissions of clinical and laboratory data, a new field is open for instantaneous medicosurgical examination and consultation. Thus an interchange of medical and scientific information from and to any distant place is possible. The application of this new method will prove useful therapeutically for both patients and doctors and it should result in a more complete and satisfactory mutual understanding among all doctors and scientists throughout the world.

Summary

Short wave radio and telephoto transmission make it possible to communicate instantly, at any distance, all pertinent clinical and laboratory findings in patients with heart conditions. The first successful transatlantic audiovisual transmissions of cardiac auscultation, including clinical data, roentgenogram, electrocardiogram, and cardiochart from New York to Paris and Rome and back have been accomplished. The audible heart sounds were transmitted by radio through sound tape. The complete visual records were transmitted by radiophotography.

The transmission was successfully received in Paris and Rome, and the sound fidelity as well as the picture quality were crosschecked in New York by immediate retransmission of the records after their reception abroad. This new system can be used in all fields of medicine, surgery, and obstetrics in all parts of the world.

STAPHYLOCOCCUS AUREUS IN AIR OF AN OPERATING ROOM

Harold W. Wolf, M.S., Marvin M. Harris, Ph.D.
and
Wesley R. Dyer, M.D., Savannah, Ga.

Air-sampling for bacteriological studies was carried out in an operating room for nine days, during which 27 patients were operated on. The 34 colonies of Staphylococcus aureus so obtained were studied as to bacteriophage type. The most frequent type was 80/81. The colonies differed as to sensitiveness to most of the eight antibiotics tested, but all colonies were sensitive to polymyxin B. Eight of the colonies proved sensitive to every one of the antibiotics tested, but there was one colony, not typable, that was resistant to chlortetracycline, chloramphenicol, erythromycin, penicillin, oxytetracycline, and tetracycline. Nontypable colonies were obtained from the nares of two persons working in the operating room. One postoperative infection occurred; the organism concerned was a staphylococcus of type 80/81.

In March, 1958, the U. S. Public Health Service Hospital in Savannah, Ga., created an interdepartmental committee on infections as recommended by the Conference on Staphylococcic Infections in the Hospital and Community.[1] This committee initiated a program to determine the extent of the potential staphylococcic problem within this hospital and requested the assistance of the Technical Development Laboratories of the Communicable Disease Center, also located in Savannah, with the phase of the program concerned with airborne organisms. This paper presents a discussion of some of the findings in air-sampling work conducted to date.

Staphylococcus aureus has been isolated from the air of surgical wards,[2] nurseries,[3] and burn dressing rooms,[4] as well as operating rooms.[5] In spite of this rather common prevalence, the role of air in the transmission of hospital-acquired infections is still

---

From the Communicable Disease Center, Bureau of State Services, Public Health Service, U. S. Department of Health, Education, and Welfare, Technical Development Laboratories (Mr. Wolf and Dr. Harris) and the Public Health Service Hospital, Bureau of Medical Services, Public Health Service, U. S. Department of Health, Education, and Welfare (Dr. Dyer).

not clearly defined. Clarke and co-workers,[2] after studying Staph. aureus wound infections in two surgical wards, concluded that spread by contact was the most important route and that efforts to limit spread by contact would be more fruitful than measures directed at airborne bacteria. Nevertheless, Shooter and co-workers [6] reversed the direction of air flow through an operating room so that air entered the theater from out-of-doors instead of from a hospital corridor and thereby reduced the total bacterial counts of the room as well as the number of postoperative infections. One of the latest studies to be reported has been that of Kinmonth and others,[7] in which a curved tube was attached to the inlet of a slit sampler and the open end of the tube was exposed adjacent to the incision of individuals on the operating table. Staph. aureus was recovered on only six occasions, and two Staph. aureus infections occurred when no Staph. aureus was detected in the air. It was concluded that there seems to be little relationship between the development of postoperative sepsis and the presence or absence of Staph. aureus in the theater air. However, the technique of adding a curved tube to the inlet of a sampler, and drawing air through this tube in order to obtain a sample, is a questionable one, since the heavier particles will most likely be trapped in the tube and will not reach the sampler.

Methods of Study

The PHS Hospital in Savannah has a capacity of 150 beds. It was constructed in 1906. The operating theater is on the third floor and comprises a suite of rooms, as shown in figure 1. The rooms are all interconnected and are located adjacent to the main third-floor corridor. Air from outdoors passes through a system of filters and a refrigerated water spray (or through steam-heated coils in cold weather), enters the main operating room under positive pressure through four ceiling diffusers, and leaves through the doorways. An outlet specifically for air is not provided in the main operating room. The air is not recirculated. Temperatures during the sampling days ranged from a low of 64 F to a high of 76 F, and relative humidities ranged from 37 to 78%. The rooms are also warmed by means of steam radiators.

A Casella slit air sampler was used in this survey and was set up in the main operating room near the scrub room door. Settling plates were simultaneously exposed near the slit sampler. The approximate location is shown in figure 1. The site selected for the sampler was based on the desire to obtain as good a sample of air as possible without interfering with the surgical team. It was set up 6 to 8 ft. from the operating table at approximately the same elevation as the table and near an open door through which outgoing air passed.

Two types of mediums were used in the sampling activities, 5% defibrinated sheep blood heart infusion agar and Chapman-Stone (Difco) agar. One or the other medium was used in the slit sampler for an entire day. With the settling plates, both mediums were exposed simultaneously except for one day when blood agar plates only were exposed.

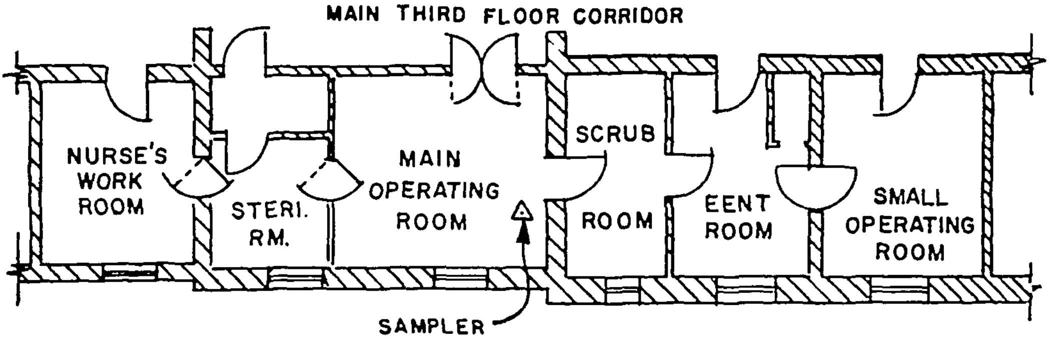

Fig. 1.—Operating suite, PHS Hospital, Savannah, Ga. (scale: 1/16 in. equals 1 ft.).

The slit sampler was operated at a rate of 0.97 cu. ft. per minute. Plates were exposed in this sampler for different intervals of time, varying from 5 to 15 minutes for blood agar plates and 10 to 20 minutes for Chapman-Stone agar plates.

Blood agar plates were incubated at 37 C for 48 hours. Chapman-Stone plates were incubated at 37 C for 24 hours followed by 30 C for 48 hours. All suspicious-looking Staph. aureus colonies on blood agar were streaked on Chapman-Stone agar. Golden-colored colonies on Chapman-Stone agar were transferred to heart infusion agar slants. Gram stains of these transplants were made and coagulase tests performed. In no case was a golden-colored colony on Chapman-Stone agar found which was not coagulase positive. Total colony counts were made on the blood agar plates after 48 hours' incubation at 37 C. A golden-colored colony on Chapman-Stone agar showing gram-positive cocci in typical cluster arrangement and coagulase-positive characteristics was considered as Staph. aureus. The tube coagulase test was employed using desiccated rabbit plasma (Difco). A careful record of the activities in the operating room was maintained while sampling was being done.

Findings

Air-sampling activities were conducted in the main operating room on nine days between March 31 and June 6, 1958. A total of 27 patients were operated on during the sampling days; 3,276.3 cu. ft. of air was sampled in the slit sampler, 1,685.0 on blood agar, and 1,591.3 on Chapman-Stone medium. Blood agar settling plates were exposed a total of 3,748 minutes and Chapman-Stone plates 3,189 minutes.

At least one colony of Staph. aureus (as identified above) was recovered on each of the nine sampling days. The frequency of distribution was as follows: one colony was recovered on each of three days, 2 colonies on each of two days, 3 colonies on one day, 6 colonies on each of two days, and 12 colonies on one day.

Phage Types and Antibiotic Sensitivities of Staphylococcus Aureus Sampled from Air of Operating Room

* Phage typing by Communicable Disease Center laboratory branch facilities, Chamblee, Ga.
† Intermediate-strength Difco disks. S = sensitive; R = resistant.

Recoveries of Staph. aureus with the slit sampler for the two mediums totaled 18 colonies on blood agar and 12 colonies on Chapman-Stone agar. Correcting for the difference in volume sampled, this represents a yield of Staph. aureus–bearing particles per 100 cu. ft. of 1.07 for blood agar and 0.76 for Chapman-Stone agar, or a ratio of 1.41 to 1. Laboratory tests of the same two mediums, with use of phage types VA4 isolated from an infection and 80/81 isolated from the air, were made in which the two mediums were inoculated with equal volumes of dilute suspensions. The ratios of recoveries on blood agar versus Chapman-Stone agar obtained from these tests were 1.30 to 1 for the VA4 strain and 1.67 to 1 for the 80/81 strain. These ratios show that the recoveries of Staph. aureus from the operating room air with these two mediums are of the same order as would be expected based on laboratory findings.

Only four colonies of Staph. aureus were recovered on Chapman-Stone settling plates. None was recovered on blood agar settling plates. This was probably a chance phenomenon with no relationship to particle size or the kind of medium employed.

All 34 Staph. aureus colonies isolated from the air of the operating room were phage typed. Fourteen were 80/81, nine VA4, and three not typable, while the remaining cultures consisted of one each of the following types: 6,77; 44A; 47; 7; 52A,80; 29,52,52A,80; 52A; and 79. Sensitivities of the Staph. aureus isolated from the air of the operating room were checked against eight antibiotics with use of intermediate-strength Difco disks. The presence of a zone of inhibition without regard to size was interpreted as indicating sensitivity. The order of decreasing effect was as follows: (*a*) polymyxin B, 100% sensitive; (*b*) erythromycin and penicillin, 97% each; (*c*) chloramphenicol (Chloromycetin), 88%; (*d*) chlortetracycline (Aureomycin) and tetracycline, 62% each; (*e*) streptomycin, 29%; and (*f*) oxytetracycline (Terramycin) 27%. The table summarizes the phage types and sensitivities of these colonies.

Two of the operating room staff harbored Staph. aureus in their nares, as determined by single cultures taken by the infections committee. The Staph. aureus in both of these individuals were of a strain that was not phage typable and were resistant to penicillin. During the course of the air-sampling studies, only one colony of Staph. aureus which fits this pattern was isolated from the air. This was obtained 10 days after the cultures were taken from the staff and was the only Staph. aureus recovered on that day. Both individuals were in the operating room at the time this organism was sampled.

The mere recovery of one or two Staph. aureus colonies from the air in a day's sampling time does not provide much of a picture unless the sampling procedure is continued long enough to permit the emergence of some sort of pattern. However, when 6, or better yet, 12, isolates are obtained in a day's sampling, some patterns become apparent.

Data from the three days on which these numbers were recovered from the air of the operating room during the course of this survey are shown in figures 2, 3, and 4. Figure 2 represents the results of May 21, when Chapman-Stone agar was used in the slit sampler. The arrows above the time scale indicate the length of time the slit sampler was operating. Each black dot denotes a Staph. aureus recovery and is *positioned chronologically.* The number above each dot denotes the phage type. The arrows underneath the time scale denote the time interval from the initial incision to the final suture. On this day, all Staph. aureus recoveries were obtained after the lunch hour. In spite of the apparently heavy exposure (5.4 Staph. aureus per 100 cu. ft. of air sampled) of the hernia patient, neither he nor any other patient this day developed a postoperative infection.

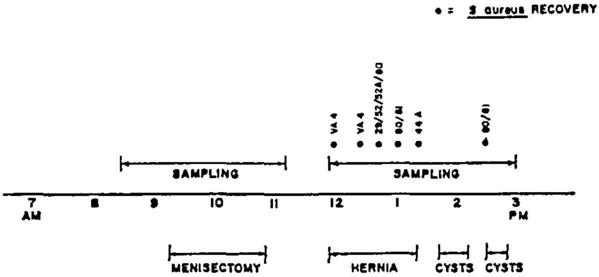

Fig. 2.—Staphylococcus aureus recoveries in main operating room, May 21, 1958.

Figure 3 represents the results of April 21, when blood agar was used in the slit sampler and total counts obtained. Again, the arrows indicate actual intervals of operations, the dots represent Staph. aureus recoveries, and the numbers above denote the phage types. All cultures were phage type VA4. A point of interest on this day was the three colonies that were obtained on the sample which was exposed while the room was swept with a hair broom. The only time a broom was used in the operating room of this hospital was at the end of the day when the amount of debris (mostly sutures) on the floor was too great to be picked up individually by hand. (A mop dampened by a disinfectant solution has now been substituted.)

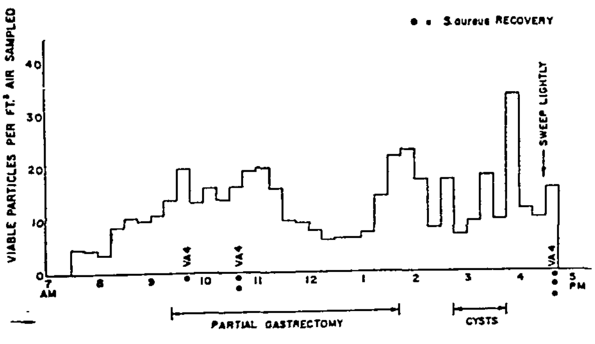

Fig. 3.—Bacterial counts and Staphylococcus aureus recoveries in main operating room, April 21, 1958.

Figure 4 represents the day when the highest recoveries were made (23 Staph. aureus per 100 cu. ft.) and the day a patient became infected. *This patient had a biopsy performed on his right* femur. All four Staph. aureus colonies isolated from the air by the slit sampler while this patient was undergoing surgery as well as the two recovered from the settling plate were phage type 80/81. The subsequent postoperative infection suffered by this patient was due to an 80/81 Staph. aureus.

At the end of this day, the room was swept with a hair broom. Two Staph. aureus colonies were sampled from the air at this time. One was a phage type 7 and the other an 80/81. The sample that followed this was accidentally broken and consequently it is not known how rapidly the Staph. aureus–bearing particles which were apparently stirred up by the sweeping might have settled out. However, none was recovered from the following and last sample of the day, which was taken approximately 10 minutes after sweeping ceased. Duguid and Wallace[8] demonstrated that 90% of the bacteria-carrying particles disappear for various reasons within 35 minutes after an unventilated room is vacated.

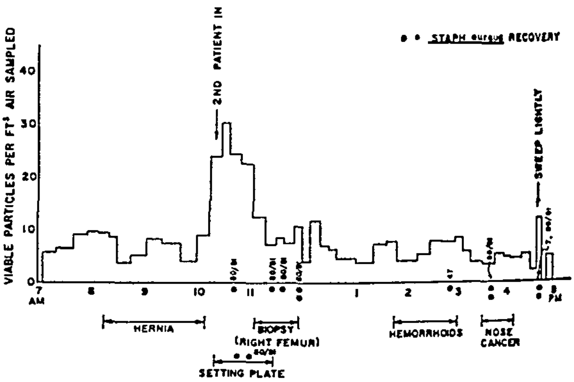

Fig. 4.—Bacterial counts and Staphylococcus aureus recoveries in main operating room, June 6, 1958.

Comment

According to the results with the slit sampler, two individuals were exposed to relatively high concentrations of airborne Staph. aureus. The patient of May 21 did not suffer a subsequent postoperative infection, while the patient of June 6 did. If airborne Staph. aureus was the source of the infection and all the many other variables are equated, what differences can be found in the two cases? First, the May 21 patient was exposed to a peak concentration of 5.4 Staph. aureus–bearing particles per 100 cu. ft., whereas the June 6 patient was exposed to a maximum of 23 per 100 cu. ft. Second, no Staph. aureus colonies were recovered from settling plates on May 21, whereas two were recovered prior to or during the operation of June 6 (a settling rate of 26.5 Staph. aureus–bearing particles per square foot per minute). And third, three different phage types were recovered during the critical interval of May 21, whereas all those recovered during a similar interval of June 6 were of the one type, 80/81.

The data of May 21 and June 6 both indicate a sudden influx of the Staph. aureus into the air of the operating room. (As demonstrated by Shooter and others,[9] Staph. aureus, when present in comparatively large numbers, appears to enter in an explosive manner.) April 21 would have been a "low-yield" day had it not been for the three colonies recovered while the room was swept. The data of May 21 suggest that the operating room personnel and/or the patient brought the organisms in with them after lunch, since no Staph. aureus–bearing particles were obtained prior to lunch and the same personnel were present during the entire day. The data of June 6 show that the patient probably brought the Staph. aureus into the room, since none was recovered prior to his entering and the operating room personnel consisted of the same individuals. This does not eliminate the operating room personnel, since several did leave the operating room for short periods between operations and return.

Conclusions

While we agree that the data of this study are extremely limited, certain findings are worthy of the attention of surgical personnel. 1. A postoperative infection occurred in a patient who was exposed to a relatively high concentration of airborne Staphylococcus aureus of the so-called epidemic strain 80/81. The attending surgical staff were not nasal carriers of this phage type. 2. Sweeping the operating room floor with a hair broom can introduce Staph. aureus into the air. 3. One Staph. aureus–bearing particle was recovered from the air which was similar to the Staph. aureus found in the nares of two individuals among the surgical staff. 4. Staph. aureus, when present in comparatively large numbers, appears to enter in an explosive manner. This entrance might be attributable to the patient or to recent contact of the operating room staff with a source.

THE GOOD GENERAL PRACTITIONER.—In addition to being the most numerous section of the medical community, the general practitioners are also the most important. . . . He . . . best knows the family history and environment of the patient, and he alone is the arbiter as to where to send the patient in case expert opinion or special treatment is required. . . . The doctor has the highest of all human privileges, to wit, helping others in their troubles, relieving them in their pain, and comforting them in their sorrows. This must, and should, compensate for all the long hours of work, all the heavy responsibilities, and the commonly all too meager financial reward. . . . Now to consider the qualities that should tend to make one a success in general practice. . . . To my mind, the really outstanding qualities are kindness, tenderness and understanding, which enable one to treat the patient rather than the disease. Never forget, no matter how interesting the clinical picture may be, that you are there first and foremost to bring relief to a human being. In nine cases out of ten you will find out that peace of mind is what is being sought rather than ease of body. Especially in the age we live in, when education is more universal . . . and the radio and Press of extreme power, you will tend to find that every pain in the chest is imagined to be heart disease, and every abdominal pain is due to cancer. Fear is the real bogey you will have to fight, and you can't fight fear unless you understand men. Hence, I stress once more that you will be treating human beings more than disease.—D. W. Macnamara, M.B., B.Ch., The Good General Practitioner, *The Journal of the Irish Medical Association,* February, 1959.

PSEUDO-PSEUDOHYPOPARATHYROIDISM

REPORT OF A CASE WITH ASSOCIATED CARDIOPULMONARY SYNDROME OF OBESITY

Thomas R. Casey, M.D., Bernhard B. Fast, M.D.
and
Reuben M. Cherniack, M.D., Winnipeg, Manitoba, Canada

The term pseudo-pseudohypoparathyroidism is applied to a condition in which a patient with dyschondroplasia and ectopic bone formation responds to administration of parathyroid hormone. The patient here described, a 61-year-old woman, had a round facies, short stature, shortened metacarpals and metatarsals, symmetrical deformities of both elbows, and lens opacities. Her response to parathyroid hormone was not studied, but determinations of calcium and phosphorus in her blood suggested normal parathyroid function. Hospitalization was made necessary by excessive drowsiness associated with alveolar hypoventilation and obesity. The patient left the hospital much improved after achieving a weight-reduction of 9 kg. (20 lb.).

In 1942, Albright and others[1] described a familial metabolic disorder characterized by clinical and biochemical signs suggestive of hypoparathyroidism along with a number of physical defects including short stature, broad face, poor mental development, short metatarsals and metacarpals, and ectopic calcification. Intravenous administration of parathyroid hormone (Parathormone) failed to produce the expected phosphate diuresis, and normal or hypertrophied parathyroid glands were noted. This was considered to represent a failure of end-organ response, and the term pseudohypoparathyroidism was coined. In 1952, Albright and others[2] reported the case of a patient with all the physical characteristics of pseudo-hypoparathyroidism but having normal serum calcium and phosphorus levels. The term pseudo-pseudohypoparathyroidism was suggested for this entity and, since the original description, six cases have been reported. The case of pseudo-pseudohypoparathyroidism reported here was complicated by the patient's obesity and alveolar hypoventilation.

Report of a Case

A 61-year-old housewife was admitted to hospital on April 22, 1958, complaining of excessive drowsiness. She had had difficulty with her arms since birth. Her parents and siblings were apparently normal. She had no children.

The patient's face was round and she was short of stature, being 4 ft. 10 in. (147 cm.) tall. Her weight on admission was 228.5 lb. (113.6 kg.) (fig. 1A). Marked mental impairment was noted, and cyanosis, which increased with recumbency or sleep and decreased in the upright position or with hyperventilation. Her right pupil was irregular in shape and there were bilateral lenticular opacities.

The patient was obese, with increased thoracic kyphosis and anteroposterior diameter. There was generalized dulness to percussion over the chest, breath sounds were distant, and there were no adventitious sounds. The apex beat was not palpable. Blood pressure was 140/80 mm. Hg. The abdomen was barrel-shaped and no organs or masses could be felt through the obese abdominal wall.

The patient's legs were short, with pitting edema halfway to the knees. She had difficulty extending both elbows, and movement in the right shoulder was painful and reduced in all directions. Both hands were short and there was displacement of the first, second, and fifth metacarpophalangeal joints on the right hand and the second, fourth, and fifth on the left, with dimpling of the knuckles (fig. 1*B*). No finger clubbing was noted, but the nail beds were deeply cyanotic. Her lower extremities appeared structurally normal.

External genitalia were normal, as was the distribution of hair. No tendon reflexes were elicited and plantar responses were normal. Intertrigo was present in the folds of fat, particularly beneath the breasts.

Laboratory studies yielded the following results: No abnormalities in the urine; hemoglobin level was 16.5 Gm. per 100 ml., erythrocytes 5,500,000 per cubic millimeter; hematocrit value 58%; blood sedimentation rate (Westergren) 7 mm. per hour; and leukocytes, 8,500 per cubic millimeter with a normal differential and platelet count. Serum calcium and phosphate levels, measured on two occasions, were 10.7 and 10.4 mg. per 100 cc., and 4.2 and 5.0 mg. per 100 cc. respectively. Alkaline phosphatase levels, measured on the same occasions, were 10 and 11 King-Armstrong units. The electrocardiogram showed S-T segment depression in 1, 2, aVL, aVF, and from V_2 to V_6. The electroencephalogram was of low amplitude but no abnormality was seen.

Chest roentgenograms showed the heart to be increased in width, with abnormal hilar shadows and pulmonary vascular detail. Skull roentgenograms revealed a small area of calcification or ossification in the falx cerebri. Roentgenograms of the right hand demonstrated shortened first, second, and fifth metacarpals, while the second, fourth, and fifth metacarpals were shortened in the left hand (fig. 2A). The metatarsals of the left great toe were considerably shortened. Roentgenograms of both elbows showed identical deformities (fig. 2*B*), the proximal end of the radius being distorted and articulating with the anterior surface of the humerus close to the capitellum, which was irregular. There was excessive new bone formation around the proximal end of the radius and a suggestion of ectopic ossification around the joint. Roentgenograms of the spine revealed no further abnormalities.

From the Department of Medicine, University of Manitoba, and the Clinical Investigation Unit, Department of Medicine, Winnipeg General Hospital. Dr. Cherniack is a Markle scholar in medical science.

It was impossible to complete respiratory function studies because of the patient's lack of comprehension and mental dulness. Arterial blood and blood volume studies are shown in the table. It can be seen that there was alveolar hypoventilation with hypoxia, hypercapnia, and moderate polycythemia and that 15 seconds of hyperventilation produced an improvement in the level of blood gases.

Treatment in hospital consisted of an 800-calorie reducing diet, D-amphetamine in daily doses of 10 mg. and analgesics. At discharge from hospital the patient had lost 20 lb. (9.1 kg.) and there was distinct improvement in her color, energy level, and quality of breathing.

Comment

The physical features of a round face, short obese stature, mental dulness, short metatarsals and metacarpals, and normal serum calcium and phosphorus values support the diagnosis of pseudo-pseudohypoparathyroidism. There was no calcification of the basal ganglions, but ectopic ossification was present. The lenticular opacities and the diffuse, low-voltage electroencephalogram are other features previously described. The patient's response to parathyroid hormone was not determined, but the levels of calcium and phosphorus suggest normal parathyroid function. The low-voltage electroencephalogram is of interest but should perhaps not be attributed to this syndrome since hypoxia and hypercapnia may be reflected as nonspecific electroencephalographic changes.[3]

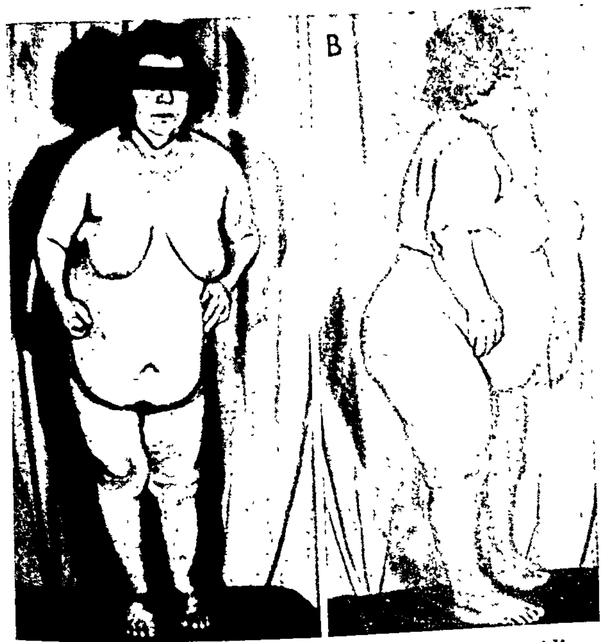

Fig. 1.—Patient with pseudo-pseudohypoparathyroidism; short stature, obesity, deformed arms, and dimpling of knuckles. *A*, anterior view; *B*, lateral view.

The association between obesity and alveolar hypoventilation, secondary polycythemia, and cor pulmonale in the absence of pulmonary disease has recently received considerable attention.[4] The possibility of alveolar hypoventilation with obesity was considered when the patient was noted to be deeply cyanotic and to twitch while asleep. When first admitted she slept almost constantly if not disturbed. She was always startled when aroused, and took several quick breaths which improved her color. The findings of reduced minute volume, hypoxia, and hypercapnia with increased blood volume, increased red blood cell mass, and elevated hematocrit values in the absence of clinical pulmonary disease confirmed the diagnosis of alveolar hypoventilation and secondary polycythemia. These studies were obtained while the patient was awake. Her striking color changes when asleep suggest that the gas tensions would have been markedly abnormal had they been obtained while she was asleep. That these findings were due to the presence of obesity can only be postulated since it was not possible to repeat the studies after

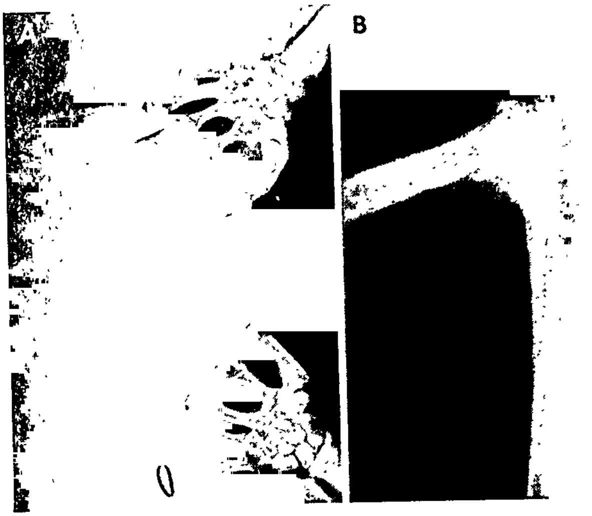

Fig. 2.—*A*, roentgenogram of both hands; shortened first, second, and fifth metacarpals of right hand and second, fourth, and fifth metacarpals of left. *B*, roentgenogram of elbow; irregularity and displacement of elbow joint with excessive bone formation around proximal end of radius.

† Value in parentheses obtained during hyperventilation.

the patient's 20-lb. weight loss, but the clinical improvement indicates the possible association, in her case, of excessive weight and altered arterial blood gases. In addition, the marked improvement in arterial oxygen tension after slight hyperventilation further suggests that the lungs were normal. It is of interest that it was the symptoms resulting from alveolar hypoventilation which led to the hospital admission of this patient.

In addition to the original case six patients with pseudo-pseudohypoparathyroidism have been reported in the world literature. In 1955, Miles and Elrick[5] described a 25-year-old woman with the typical physical features including lenticular opacities but without ectopic calcification. Roche and others[6] described a 40-year-old man with dyschondroplasia and ectopic calcification but normal configuration and facial contour. In addition, he was noted to have blue scleras. Wallach and others[7] in October, 1956, described a 24-year-old man with striking subcutaneous ossification but neither short metacarpal and metatarsal bones nor short stature and round face. The dyschondroplasia was restricted to short distal phalanges. He also had gout, unexplained splenomegaly, lymphoid hyperplasia, and asymptomatic rheumatoid spondylitis. McNeely[8] and others described a 24-year-old man manifesting brachydactylia and short stature with soft tissue calcification and ossification. Seringe and Tomkiewicz[9] recently reported two sisters, aged 15½ and 10½, who were short, bordering on dwarfism, with short necks, slightly rounded facies, and pronounced brachymetapody. In both patients and in the otherwise normal mother blue scleras were noted. In 1956, Cusmano and others,[10] in a report of six cases of pseudo-hypoparathyroidism, mention that the mother of one of the patients in the series showed short stature, short metacarpals and metatarsals, and undoubtedly represented a further case of pseudo-pseudohypoparathyroidism.

Albright's concept of the syndrome of pseudohypoparathyroidism was that it consists "of several unrelated genetic defects which occur simultaneously," including unresponsiveness to parathyroid hormone, dyschondroplasia, and ectopic bone formation. The term pseudo-pseudohypoparathyroidism was applied by Albright to individuals with the second and third defects but without the first; thus, the initial report on pseudo-pseudohypoparathyroidism tended to confirm the view that dyschondroplasia and ectopic bone formation were genetically separate from the failure of responsiveness to parathyroid hormone. The term pseudo-pseudohypoparathyroidism is perhaps an unfortunate one since it has suggested to some that it is a forme fruste of pseudo-hypoparathyroidism. Discovery and definition of the metabolic errors distinguishing these defects will undoubtedly provide a more useful term.

Summary

A 61-year-old woman with round facies, short stature, shortened metacarpals and metatarsals, lens opacities, and normal parathyroid function fulfilled the criteria for a diagnosis of pseudo-pseudohypoparathyroidism. Her excess weight and abnormal respiratory function satisfied the necessary requirements for the diagnosis of alveolar hypoventilation associated with obesity. Excessive drowsiness associated with the alveolar hypoventilation probably precipitated the hospital admission.

TREATMENT OF ACUTE TYPHOID WITH SYNNEMATIN B

REPORT OF A CASE

Norman D. Henderson, M.D., Lansing, Mich., Fred C. Garlock, M.D., Grand Ledge, Mich.
and
Birger H. Olson, Ph.D., Lansing, Mich.

The use of synnematin B in the treatment of typhoid in infants and children in the Hospital Infantil, Mexico City, was reported in 1955 by Benavides and associates.[1] Synnematin B was shown to be effective in the treatment of acute typhoid as indicated by the fact that no deaths or perforations were observed in this series of cases. It is of interest to note that Salmonella typhi was cleared from both blood and feces of all patients and that no indications of toxicity referrable to the drug were reported. Of further significance is the fact that the development of the carrier state has not been observed in any patient adequately treated with synnematin B.

The present report is believed to be the first paper published on the clinical use of synnematin B in typhoid in the United States. It is an account of acute typhoid in an adult which responded dramatically to treatment with synnematin B after failure of chloramphenicol (Chloromycetin) to effect a favorable clinical response.

A patient with a severe systemic infection was treated unsuccessfully with penicillin, chloramphenicol, and a third unidentified antibiotic. Salmonella typhi was cultured from blood and feces and was found sensitive to synnematin B. The condition of the patient had become very critical when therapy with synnematin B was begun, and it continued to be critical during the first 48 hours. Thereafter, improvement was rapid. Eleven days after discharge the patient was readmitted with typhoid peritonitis ascribed to rupture of an infected ovarian cyst. From this setback the patient recovered without any antibiotic treatment, and subsequent tests indicate that she is not a carrier. Her son and father-in-law also had mild forms of typhoid; they recovered on treatment with chloramphenicol.

The patient's family, consisting of husband, wife, and son, entered Mexico for a vacation on Feb. 6, 1956. On Feb. 16, the wife developed mild diarrhea which persisted until Feb. 20. The family returned to Michigan on Feb. 25. On Feb. 27 the patient noted a return of malaise and diarrhea and had a chill, and on Feb. 29 she developed fever, headache, cough, and occasional chill. Treatment for three days with penicillin and an unidentified wide-spectrum antibiotic ordered by a local physician was ineffective. From March 3 to March 9 she had no treatment and became progressively worse. On March 9, one of us (F. C. G.) made a clinical diagnosis of typhoid and started oral treatment with chloramphenicol (250 mg. every six hours). The patient's condition deteriorated, and she was admitted to the hospital on March 10, 1956. A summary of this case is presented in the figure.

Therapy with intramuscularly given chloramphenicol was also instituted on admission. S. typhi was isolated from both blood and feces on March 11 and 12. Results of the Widal agglutination test done on March 11 were reported as follows: S. typhi O antigen 1:10,240, H antigen 1:80, and S. paratyphi B 1:160. The patient's condition continued to deteriorate while she was on chloramphenicol therapy. On March 13, 1956, she was semicomatose and bleeding grossly from the intestine, had a spiking temperature with peaks at 104.4 F (40.2 C, oral temperature), and was considered to be in a critical condition.

Physical examination on March 12, 1956, prior to starting synnematin B therapy, revealed an acutely ill, well-nourished woman, 37 years of age, weighing 212 lb. (96.1 kg.). She was semicomatose, had a nonproductive cough, and apparently had some difficulty in hearing. Oral temperature was 104.4 F, the pulse regular at 100 per minute, blood pressure 130/84 mm. Hg, and respiration rate 32 per minute. The positive findings may be summarized as follows: typical rose spots on the abdomen, otitis media with hearing loss on the right side, acute bronchitis, and abdominal distention with tenderness which was interpreted as indicating impending perforation of the intestine. On March 12, the blood analysis was reported as follows: hemoglobin level 12.8 Gm.%, 4,010,000 red blood cells per cubic millimeter, and 4,100 white blood cells per cubic millimeter (42% segmented neutrophils, 23% nonsegmented neutrophils, and 35% lymphocytes). Urinalysis on March 12 revealed a specific gravity of 1.005, 3+ albuminuria, and 4-10 white blood cells and 3-6 red blood cells per high-power field. In view of these physical and laboratory findings, the diagnosis of typhoid was confirmed.

The cultures of S. typhi isolated from the blood and stool on March 11 were sensitive to less than 1 unit per milliliter of synnematin B. Chloramphenicol therapy was stopped after the morning dose on March 13. Therapy with synnematin B was started at 7:30 p. m. of that day with a dosage schedule of 80,000 units per kilogram of body weight per day in divided doses, intramuscularly, every four hours. In addition to synnematin B, this patient received supportive care and aspirin for temperature control. No other antimicrobial substances were used after synnematin B therapy was started.

During the first 48 hours of synnematin B therapy, the patient continued to be in a very critical condition. Rectal bleeding continued for about 24 hours but was not observed again after the first full 24-hour period of this therapy. After 48 hours of synnematin B therapy there was a dramatic change in the patient's condition. On the morning of March 16, she felt considerably improved and evidenced interest in food for the first time since being admitted to the hospital. The hearing loss on the right side disappeared, as did her cough. She was well oriented as to time and place. From this

---

From the Michigan Department of Health, Division of Laboratories (Drs. Henderson and Olson). Dr. Garlock is in private practice.

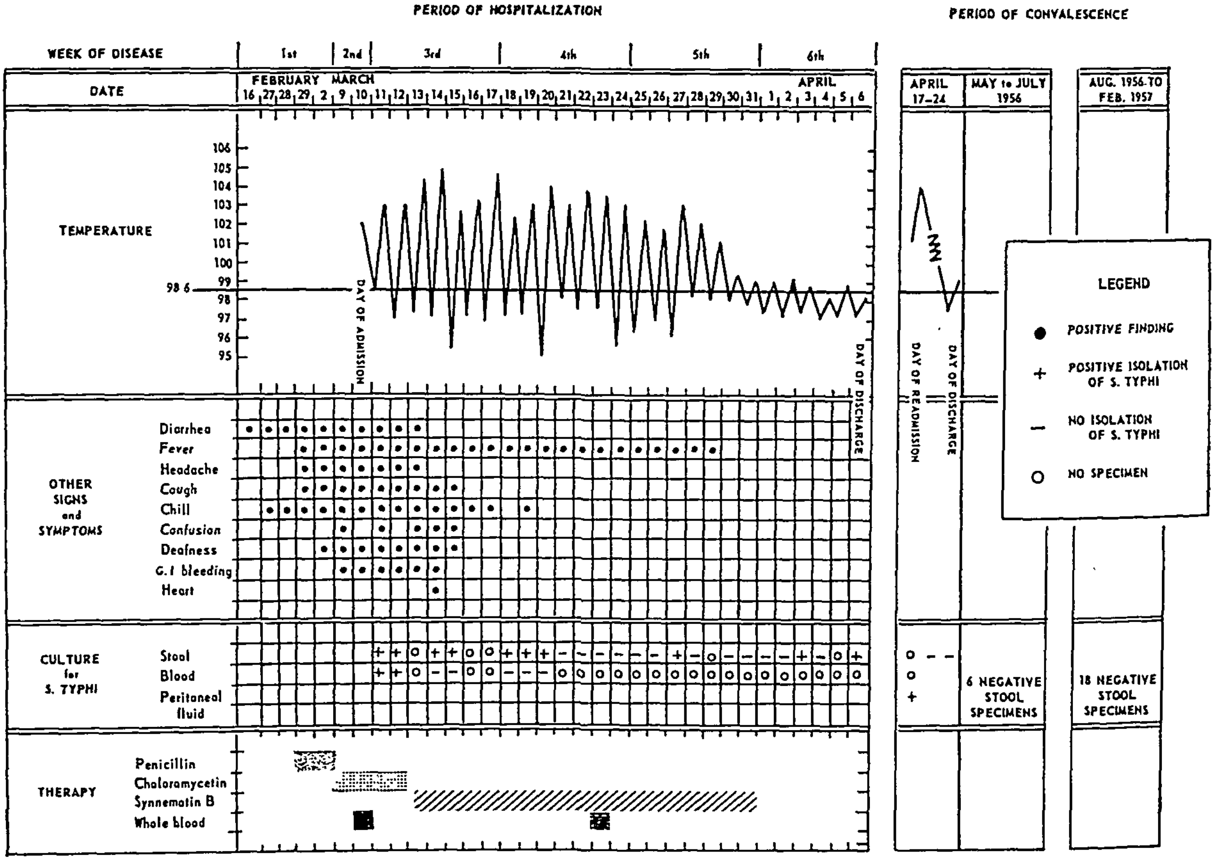
point on, she continued to make steady improvement with no indication of relapse being observed. However, her clinical course was not without incident.

On the second day of therapy, the patient developed a transitory gallop type of cardiac rhythm, followed by auricular fibrillation which was accompanied by an apical systolic cardiac murmur. In view of the tachycardia which was also present, it was felt that a complication was imminent. The abdomen was tender but not distended, and intestinal sounds were present. Perforation did not occur. The incident passed and the cardiac arrhythmia did not recur.

After the patient received 10 grains (0.65 Gm.) of aspirin when her temperature was 104.8 F (40.4 C) at 12:30 p. m. on March 14, the temperature fell progressively and by 7:30 p. m. a temperature of 95.4 F (35.2 C) was recorded. Subsequently, the dose of aspirin was limited to 5 grains (0.32 Gm.). (Osler and McRae [2] have cautioned against too vigorous use of antipyretics in typhoid.) Fever persisted throughout the course of therapy, resolving gradually by lysis; this situation has also been observed by Benavides and associates.[1] The drug therapy was stopped on March 31. The patient's condition continued to improve, and she was discharged from the hospital on April 6, 1956.

On April 17, 1956, she was readmitted to the hospital because of abdominal pain and distention. Laparotomy revealed a ruptured ovarian cyst, subsiding inflammation of the appendix, and peritonitis. A pure culture of S. typhi was isolated from the peritoneal contents. No evidence of perforation of the intestines was observed. This incident presented several unusual aspects, which will be discussed in a separate report.[3]

Because the findings at operation did not reveal intestinal perforation and there was nothing to suggest a relapse, it was decided not to give a second course of synnematin B therapy.



Graphic summary of case of typhoid treated with synnematin B.

The abdomen was closed with drainage, and the patient made an uneventful recovery. She was discharged from the hospital on April 24, 1956.

As required by the Michigan Regulations for the Control of Communicable Diseases,[4] follow-up studies were done for three months by the attending physician (F. C. G.) and the Eaton County (Michigan) Health Department with examinations of stool specimens for S. typhi. In addition, follow-up examinations were given for a period of one year with monthly examinations of stool specimens and for another year with examination of occasional stool specimens. The last positive isolation of S. typhi from the intestinal tract of this patient was on April 6, 1956. It is therefore assumed that she is not a carrier of S. typhi.

While this patient was in the hospital with typhoid, her 12-year-old son also was hospitalized and subsequently shown to have a mild case of typhoid. He was placed on chloramphenicol therapy and made an uneventful recovery, being discharged on March 24, 1956. He was also given follow-up examinations, and stool specimens were examined by the Eaton County Health Department. S. typhi was isolated from his specimens on April 30 and May 26, 1956. All stool specimens submitted since May 26, 1956, have been negative. According to the definitions set forth in the regulations, this boy would be classified as a convalescent typhoid carrier.

The father-in-law of the patient was in close contact with her during the early phase of her illness. He developed a mild case of typhoid, but he refused hospitalization and was treated at home with chloramphenicol. Stool specimens submitted by him on March 28 and 29 and on April 5, 1956, were positive for S. typhi. All subsequent specimens have been negative. This man would also be classified as a convalescent typhoid carrier. The husband of the patient did not develop any evidence of infection with S. typhi.

Comment

The response of a patient with typhoid to treatment can be judged from several points of view, including the well-being of the patient, clearance of S. typhi from the blood stream and intestinal tract, response of the fever, presence or absence of complications, duration of illness, presence or absence of toxicity, development of the carrier state, and death rate. Several of these points are applicable to the judgment of effectiveness of synnematin B in the treatment of the case of typhoid presented in this report.

As reported by Benavides and associates,[1] a definite improvement was noted in the general well-being of the patient after the first 48 hours of synnematin B therapy. At this point in the course of the disease, there was a renewed interest in food and increase in appetite, a decrease in toxic manifestation, and an improvement in mental alertness which also characterized this case. At the time synnematin B therapy was instituted, chloramphenicol had been used for four days and there was imminent danger of intestinal perforation. Smadel and co-workers[5] have emphasized the fact that serious complications, such as intestinal hemorrhage and perforation, may be expected to occur in patients treated with chloramphenicol, since the stage is generally set for such developments before therapy is instituted and time is usually required for the healing of the typhoidal lesion of the intestine. However, rectal bleeding stopped after our patient received synnematin B therapy for 24 hours and was not observed again. Inflammation of the ears and respiratory system, as represented by otitis media and bronchitis, resolved promptly without the development of mastoiditis or pneumonia. S. typhi was cleared from the blood within 24 hours after starting synnematin B therapy.

The typhoid organism was not cleared from the stool until 25 days after treatment with synnematin B was started. S. typhi was isolated from the stool specimen collected six days after antibiotic therapy was concluded. However, the organism was not isolated from the stool of this patient on any subsequent occasion. In other words, the carrier state did not develop in this patient. This result may be constrasted with that of the son, who was treated with chloramphenicol and continued to excrete S. typhi for at least two months after treatment. The fact that infants and children treated adequately with synnematin B do not develop into chronic carriers was reported in the series treated by Benavides and associates.[1] This report may be contrasted with the recent publication of O'Connor,[6] who stated that 1% of patients treated with chloramphenicol became carriers, as contrasted with 2% of the control group who received nonspecific therapy. This difference in carrier rate among the treated and control groups was not considered to be statistically significant.

It is well known that the carrier state develops most commonly in adults and that chronic carriers of S. typhi are more common among adult females than among adult males or children. Evidence summarizing the use of synnematin B in infants and children and in the one adult reported here indicates that the chronic carrier state does not develop among adequately treated patients. However, the influence of synnematin B on the development of the carrier state in adults awaits further evaluation.

During the first two days of synnematin B therapy, the patient continued to be critically ill with a rising temperature. Previous work[7] with synnematin B has shown that the drug is bactericidal in its action. It is our belief that this bactericidal action, combined with the defense mechanisms of the host, resulted in the release of a considerable quantity of typhoid endotoxin into the circulation. This substance, known to be pyrogenic, is thought to be responsible for the continued fever and chills observed in this patient during the course of therapy with synnematin B.

The possibility must also be considered that synnematin B is pyrogenic and that the drug was responsible in part for the high temperature. The fever curve indicates that the temperature was returning toward normal by lysis during the last seven days of therapy. Also, the injections were continued for 30 hours after the patient became afebrile. Our own studies[8] in human volunteers, patients with urinary tract infections, and animals have not revealed any pyrogenic tendency on the part of synnematin B. Therefore, we have concluded that synnematin B is not pyrogenic. No evidence of toxicity which could be attributed to synnematin B was observed in our patient. A similar observation was made by Benavides and assocates.[1]

The isolation of S. typhi from the peritoneal contents at the time of the second admission raises the questions of perforation and relapse. There was no evidence to support a diagnosis of relapse. Therefore, the patient was not treated further with synnematin B.

Since bacteriological examination of the liquid contents of the peritoneal cavity revealed a pure culture of S. typhi, in all probability it did not arise from a perforation of the intestines. When intestinal perforation does occur, the peritoneal contents usually yield a mixed culture, representative of the contents of the intestines at the time of perforation.

The biopsy of the cyst during laparotomy revealed the typical structure of an endometrial cyst of the ovary. If this cyst contained S. typhi after the septicemia of the acute illness, a rupture of the cyst would produce a pure culture typhoid peritonitis. Therefore, the most probable explanation would be that the S. typhi was walled off in the cyst during the acute phase of the disease. This conclusion would agree with the coincidence between the ruptured ovarian cyst and the peritonitis without perforation, as well as the pure culture of S. typhi reported by the bacteriologist. A more detailed discussion of this incident will be reported in a separate paper.[3]

Summary

A patient with acute typhoid was treated, with good response, with synnematin B. No perforation occurred, the patient rapidly regained a feeling of well-being, and there was no evidence of toxicity after the use of synnematin B. The patient developed peritonitis associated with a ruptured endometrial cyst of the ovary early in the convalescent period. The carrier state did not develop, as evidenced by follow-up studies extending over a period of two years.

Michigan Department of Health, Division of Laboratories, DeWitt Road (4) (Dr. Henderson).

J. M. Cook, M.D., director, and the staff of the Eaton County (Michigan) Health Department assisted in completing surveillance during convalescent period.

FAVORABLE RESPONSE IN THE CLINICAL TREATMENT OF CHRONIC ALCOHOLISM

Robert E. Thomas, M.D., Lester H. Gliedman, M.D.,† Julia Freund, M.A., Stanley D. Imber, Ph.D.
and
Anthony R. Stone, M.S.S.W., Baltimore

The community clinic approach for the rehabilitation of chronic alcoholics is being used with increasing frequency in the United States. In line with this trend, Maryland has established six county alcoholic rehabilitation clinics through the collaboration of state and local health departments. These were set up as part-time evening clinics and staffed with personnel representing the traditional psychiatric team plus a public health nurse. Treatment methods consisted of individual and group treatment of the alcoholic and occasionally of the spouse. In order to develop, extend, and improve the program, it was felt necessary to appraise the effectiveness of the services offered. A survey was initiated to meet this need. One of the major goals was the identification of some of the factors which contribute to a favorable outcome in the clinical treatment of alcoholism. In this paper only data relevant to these favorable factors are described.

The records of 57 men and 20 women patients in six county rehabilitation clinics for alcoholics were studied in order to identify the factors favoring recovery. Treatment included both individual and group psychotherapy. Criteria of improvement included the amount or frequency of alcohol-consumption, family and social adjustment, occupational adjustment, and physical appearance, and 42% of the patients improved on three or more of these criteria. The greatest improvement was found in those who attended the most treatment-sessions, whose spouses participated in the sessions, and whose relatives received routine social service contacts. The people attracted to these clinics were of a socially stable type in extreme contrast to the alcoholic stereotype. The unusually favorable results obtained demonstrate the importance of considering groups, especially the family, in future planning for the outpatient treatment of chronic alcoholism.

Chief of the Division of Mental Health, Maryland State Department of Health (Dr. Thomas); Assistant Professor of Psychiatry, Johns Hopkins University (Dr. Gliedman); Public Health Nursing Consultant, Maryland State Department of Health (Miss Freund); Assistant Professor of Medical Psychology, Johns Hopkins University (Dr. Imber); and Instructor in Psychiatry, Johns Hopkins University (Mr. Stone).

†Dr. Gliedman died May 20, 1958.

A multidisciplinary research team developed special rating scales, information schedules, and interviews to evaluate the treatment results of the six clinics. These scales were given to the therapists who completed them retrospectively for each of the patients in treatment during the three-month survey period. The sample of 77 patients and 12 spouses was studied from the standpoint of selected personality attributes, amount and type of therapy, attendance at clinics, and therapeutic changes as measured by multiple criteria.

TABLE 1.—*Percentage Change in Clinical Population of Seventy-seven Patients on Four Criteria of Improvement as Compared to Initial Status*

Rating	Drinking (Amount or Frequency)	Family and Social Adjustment	Occupational Adjustment		Physical Status*
			Employed	Unemployed	
Abstinent	35				
Much less	17				
Somewhat less	17				
Unchanged	26				
Somewhat more	3				
Much more	...				
Out of control	3				
Better		51	40	45†	39
About the same		42	53	45	59
Worse		7	8	10	3

* Rating based on appearance only.
† Now employed.

These criteria included (1) drinking (amount and/or frequency) as compared to initial status, rated on a seven-point scale from "abstinent" to "out of control," (2) family and social adjustment, (3) occupational adjustment (depending on whether or not the patient was employed at the start of treatment), and (4) physical status as compared to initial impression of physical condition, all compared to initial status and rated on a three-point scale from "better" to "worse."

Results

A total of 77 patients was seen in the clinics, of whom 57 (74%) were men and 20 (26%) were women. The average age was 41 years. Sixty-five per cent of the patients were married and 70% were employed. Approximately one-third of the referrals were made through the family physician; about 10% each were self-referred, referred from courts, and referred from other social agencies including public welfare; referrals from relatives comprised 6.5% and from Alcoholics Anonymous, 3.9%; and the remainder represented miscellaneous multiple sources of referral.

Treatment included both individual and group psychotherapy. Duration of treatment varied from 2 to 37 weeks, the average being 19 weeks. The average number of treatment sessions per patient was 10.3. Group patients remained in treatment for an average of 16.7 sessions, whereas patients in individual treatment remained for an average of only 6.4 sessions. Approximately two-thirds of all patients attended treatment regularly, that is, they consistently kept most of their scheduled appointments. In addition, this population was unique in that in about one-half of the cases the patients' relatives had some contact with social workers and public health nurses in the clinics during the course of the patients' treatment. Though frequently brief, and not involving treatment in the traditional sense, these contacts were concerned with family problems related to drinking. It is of special interest that 12 spouses of patients were included in a more formalized treatment program.

Progress of patients in treatment in terms of the criteria mentioned previously is summarized in table 1. It is of particular significance that 51% of the patients showed improvement in family and social adjustment alone. Twenty-three per cent of the patients were reported by their therapists to have improved on all four of the criteria employed; 19% improved on three of the four criteria; 12% on two criteria; 15% on one criterion; and 32% showed no improvement on any of the four criteria. The fact that 42% of the patients improved on three or more of the criteria is indicative of the substantial therapeutic progress of the patient population.

Table 2 shows the relationship between improvement on one or more criteria and the amount of treatment. The population was divided into those patients who had eight or more therapy sessions and those who had less than eight. Of the patients who had eight or more sessions 80% improved on two or more of the four criteria. In contrast to this group, only 26% of those with less than eight sessions of treatment showed improvement on two or more criteria. The significance of the relationship between length of treatment and improvement on the multiple criteria is highlighted by the fact that 53% of the patients with less than eight treatment sessions did not show improvement on a single criterion.

It is recognized that the improvement noted above may be only of a temporary nature, and a follow-up study would be necessary to ascertain the permanence of these positive changes. Nevertheless, the findings of this cross-sectional study seem to warrant the conclusion that a favorable response to treatment was demonstrated.

TABLE 2.—*Relationship Between Amount of Treatment and Improvement Criteria**

Criteria Showing Improvement	Patients				Total No.
	0-7 Sessions		8 or More Sessions		
	No.	%	No.	%	
0 or 1	25	74	7	20	32
2 to 4	9	26	28	80	37
Totals	34	100	35	100	69

* Data on all four criteria available only for 69 of the 77 patients in survey population. Chi-square = 19.9, $p<0.001$.

As noted previously, the ratio of male to female patients was approximately 3:1. Even though the female patients attended fewer sessions than did the men, they showed a slightly greater trend toward improvement. This improvement consisted of positive change on more of the four criteria than was true for the males and included greater reduction in drinking. Fifty-nine per cent of the women showed improvement on three or more of the criteria as compared to only 37% of the men. Approximately twice as many men as women showed no improvement on even a single criterion. Table 3 summarizes the amount of improvement in relation to patient's sex and to participation or nonparticipation of patient's spouse.

TABLE 3.—*Relationships Between Sex of Patient, and Participation or Nonparticipation of Spouse in Concurrent Therapy, and Improvement*

Patients		Treatment Sessions, Mean No.	Drinking, Mean Amount*	Percentage Showing Improvement on Criteria†‡				
Type	No.			4	3	2	1	0
Women	20	10.3	1.1	29.4	29.4	17.6	5.9	17.6
Men	57	14.6	1.7	21.1	15.4	9.6	17.3	36.5
With spouses in treatment	11	12.3	0.7	46	27	18	...	9
Without spouses in treatment ..	58	13.5	2.1	19	17	10	17	36

* Lower score = more positive change, e.g., 0.0 = abstinence.

† Because frequencies in several categories were quite low, categories 3 and 4 and 0-2 were combined.

‡ For the data comparing women and men, chi-square = 2.69, $p < .20$. For the data comparing patients with and without spouses in concurrent treatment, chi-square = 5.06, $p < .05$.

In half of the clinics a limited number of spouses was involved in active treatment in addition to that being given to the patients. Although complete data were available on only 11 of the spouses involved in treatment, this number was sufficient to permit a comparison of improvement on the four criteria between patients whose spouses were included in concurrent treatment and the remaining population. The improvement rate of patients whose spouses were also in therapy far exceeds that of the remaining population, even though the average number of treatment sessions for each of these groups was approximately the same. Of equal importance is the fact that patients whose spouses were in treatment showed greater reduction in amount of drinking. As can be seen in table 3, 73% of the patients whose spouses were in treatment evidenced improvement on three or more of the criteria in contrast to only 36% of the patients whose spouses were not in treatment. The higher quality of improvement can be seen by the fact that 46% of the patients with spouses in treatment showed improvement on all four criteria. Of those whose spouses were not in treatment only 19% showed improvement on all four criteria. Moreover, the improvement of the patients whose spouses were in treatment exceeded the levels achieved on these four criteria by the male and female patients taken separately.

The importance of active concurrent treatment of the spouse is further demonstrated in table 4. Complete data were available for 13 patients whose spouses had routine social service contacts. These were compared with those patients whose families did not receive social service attention and whose spouses were not in concurrent therapy. As can be seen, there is a suggestion of greater reduction in drinking for the 13 patients cited above. Almost three times as many patients with social service contacts showed improvement on all four criteria. However, when the data are analyzed as in table 3, no difference between these two populations is apparent. The effect of social service contacts on improvement appeared to be greater in the population receiving such service, but the improvement was less than that observed in the patients whose spouses had active, concurrent treatment.

Comment

Treatment of chronic alcoholism remains a major public health problem for which no reasonably effective approach has been developed. The analysis of the community-sponsored alcoholic rehabilitation clinics in Maryland has afforded an opportunity for appraising one of the increasingly popular means of coping with this problem as a first approximation to obtaining data for future program planning.

The three major factors contributing to favorable response to clinical treatment of chronic alcoholism described above raise important issues relative to the patterning of therapy for such patients. The first of these pertains to the nature of the population attracted by community outpatient clinics. As has already been reported,[1] these patients tend to be married and employed. Similarly, the population under study manifested more than the expected social stability and was in extreme contrast to the alcoholic stereotype. Perhaps the large proportion of this kind of alcoholic patient accounts for the substantial periods of therapy duration, regularity of attendance, and high rate of improvement achieved by patients in this study. Certainly these results were contrary to what was anticipated and compare favorably with other types of outpatient populations.[2] The "skid row" stereotype of the alcoholic may have so dominated our thinking that we have been led to underestimate the potential for improvement of the majority of patients who actually seek treatment. This highlights the need to change some of the older concepts pertaining to alcoholic patients, at least those who appear in clinics for help.

TABLE 4.—*Attendance and Improvement of Patients With and Without Social Service Contacts**

Patients		Treatment Sessions, Mean No.	Drinking, Mean Amount†	Percentage Showing Improvement on Criteria‡				
Type	No.			4	3	2	1	0
With social service contacts ...	13	17.5	1.7	38.5	...	15.4	15.4	30.7
Without social service contacts	45	12.2	2.1	13.3	22.2	8.8	17.6	37.8

* Patients with spouses in concurrent treatment are excluded for this comparison.

† Lower score = more positive change, *e.g.*, 0.0 = abstinence.

‡ Because frequencies in several categories were quite low, categories 3 and 4 and 0-2 were combined. The chi-square test is not significant.

Apparently something in the structure of the clinic attracts a certain group of alcoholic patients favorably disposed to treatment. Conceivably, the existence of these alcoholic rehabilitation clinics in a familiar agency, the health department, which already provides a broad range of preventive as well as clinical services for the family, positively influences the use of and response to these services by the patients. The fact remains that such a group of patients possesses the potential for improvement and the physician must determine those factors relevant to successful clinical treatment.

The second of the findings emphasizes one of the important factors in the recovery of these patients; namely, concurrent treatment of the family, in this case the spouse. One of us[3] has already pointed out some significant contributions of family-oriented treatment for chronic alcoholics. The involvement of the spouse has also been suggested by several other workers.[4] These investigations emphasize alcoholism as a family problem, and the implication is clear that recovery should be sought in the context of the family.

In the present investigation, patients whose spouses were in active concurrent therapy showed a significantly superior improvement in both quality and amount of change. Whether this is due to factors within the patient, the spouse, or both cannot be stated at this time, but it does seem clear that excessive drinking in a family involves more than the drinker alone. The total picture must be taken into consideration within the framework of therapy to facilitate improvement. It is also reasonable to assume that such concurrent treatment will have beneficial effects on other members of the family not immediately involved in the therapy process. Unpublished data recently gathered by us indicate the presence of an alcoholic parent in at least 25% of a group of approximately 100 psychoneurotic outpatients seeking therapy at the Henry Phipps Psychiatric Clinic of Johns Hopkins Hospital. Increased efforts at family treatment should have preventive effects on children growing up with parents who have drinking problems. Moreover, the patients whose relatives received routine social service contacts showed more improvement than those who did not receive such contacts, but less improvement than those whose spouses were in concurrent therapy. This further demonstrates the importance of active concurrent involvement of the family in the patient's recovery process.

The last important finding is that group therapy was possibly more acceptable and more advantageous to these patients than individual therapy. Group patients remained in treatment for more than twice as many sessions as patients in individual therapy. Indirectly associated with this is the finding that, on the whole, improvement depends on total amount of treatment. It is our impression that greater exploitation of the group approach, not only for patients but for spouses and family as well, should be given consideration in future planning of rehabilitation programs for chronic alcoholic patients. One of us[5] has pointed out some of the theoretical aspects of group therapy for chronic alcoholics which make it an advantageous form of treatment for this kind of population.

Summary and Conclusions

Evaluation of the Maryland alcoholic rehabilitation clinics revealed that a group of patients who were married and employed were attracted by the services offered. These patients were not essentially different in many characteristics from other psychiatric outpatients. Patients attended regularly for substantial periods of time and with good results. As a consequence of this study, it seems wise to investigate the factors in the community clinic approach which facilitate the recovery of this special population. Involvement of the family in concurrent therapy and group methods of treatment were related to the excellent response in terms of improvement shown by these patients. From this it is concluded that future planning for the outpatient therapy of chronic alcoholic patients should move in the direction of greater use of techniques which involve the family, including the establishment of family-type clinics and greater use of group treatment methods not only for the patient but also for family members.

RHEUMATIC ENDOCARDITIS COMPLICATED BY TYPHOID

Herman Sobol, M.D., Newark, N. J.

Laboratory findings can provide an early diagnosis of coexistent rheumatic heart disease and typhoid. A boy 12 years of age was hospitalized because penicillin and sulfonamide compounds failed to control a week-long episode of fever, chills, headache, nausea, and nonproductive cough. He had had rheumatic heart disease (with aortic stenosis and mitral insufficiency) four years before the admission; at the time of admission he had a fever and slow pulse rate. The cardiac state was unchanged as compared to previous examination. Absence of anemia and absence of elevated sedimentation rate and leukocyte count cast doubt on presence of either active rheumatic fover or subacute bacterial endocarditis. A gram-negative bacillus was found in the blood culture. The agglutination reaction was positive for typhoid O agglutinins. The patient was treated for and cured of typhoid with a total of 33.5 Gm. of chloramphenicol over a period of 18 days. No sequelae developed within the subsequent four years.

The early recognition of any bacteremia in a patient with rheumatic heart disease is of utmost importance. A case of rheumatic heart disease complicated by typhoid is reported because of several interesting features: 1. The coexistence of these disorders is extremely rare.[1] 2. The differential diagnosis is more than an academic exercise, because it is vital to proper therapy.[2] Early and adequate specific treatment may be rewarded by cure of the patient, whereas delay or improper treatment may result in a fatal subacute bacterial endocarditis due to a salmonella organism[3] or death may ensue from the ravages of typhoid itself.

Report of a Case

A 12-year-old boy was first seen in February, 1950. He was known to have had heart murmurs since he was 4 years of age. Although there was no classic history of rheumatic fever, the child was described as having aching legs and "growing pains." Of significance also in the history was the fact that two cousins had had rheumatic fever.

On physical examination the pertinent abnormal findings were limited to the heart and consisted of a grade 3 harsh aortic systolic murmur with a thrill and a grade 2 harsh mitral systolic murmur transmitted to the axilla. The mitral first sound was accentuated, and the pulmonic second sound was louder than that of the aortic second sound.

On fluoroscopy there was noted slight enlargement of the left ventricle, but all other chambers appeared normal. The electrocardiogram was normal, and findings on routine hemogram, sedimentation rate determination, and urinalysis were likewise normal. The diagnosis of rheumatic heart disease with aortic stenosis and mitral insufficiency was made. On subsequent yearly visits there was no change in his cardiac status.

On Jan. 23, 1954, I was asked to see the patient at his home and obtained the following history. He had been seen by a physician one week previously because of fever, chills, headache, nausea, and a nonproductive cough of two days' duration. He was given penicillin both parenterally and by mouth. When the fever and chills persisted two days later, sulfonamide drugs were also prescribed. The mother added aspirin each time the temperature went over 101 F (38.3 C), and she stated that this seemed to be the only thing that brought the temperature down but it became elevated again within a few hours. At the time of my examination the only subjective symptoms were anorexia and headache. Physical examination showed the temperature to be 101 F, the pulse rate slow and of good volume, and the cardiac findings essentially unchanged from previous examinations; there were no other significant physical findings. I suggested that the patient be hospitalized, because it was impossible at that time to determine whether he had a recrudescence of rheumatic fever, subacute bacterial endocarditis, or some other febrile disease or infection. The patient was, therefore, admitted to the Presbyterian Hospital, Newark, N. J.

On admission the temperature was 101.8 F (38.7 C), the pulse rate 90 per minute, and respirations 24 per minute. He was immediately given 15 grains (970 mg.) of aspirin, and an order was left for that amount to be given every four hours. It is common knowledge that recurrences occur in 30 to 50% of patients with rheumatic fever after a streptococcic infection,[4] and this may be so slight as to be clinically overlooked. Also, active rheumatic fever may rarely occur with a relative bradycardia.[5]

On Jan. 24 the temperature at 8 a. m. was 103.8 F (39.9 C) in spite of the aspirin. On examination, there were no localizing physical signs and one could not help but comment on the slow pulse rate relative to the height of the temperature.

Associate in Medicine, Presbyterian Hospital, unit of United Hospitals of Newark.

An electrocardiogram obtained that morning showed regular sinus rhythm with a ventricular rate of 88 per minute, P-R interval 0.12 seconds, and QRS complex 0.06 seconds. Thus, there were no electrocardiographic abnormalities. Meanwhile, blood was drawn for a hemogram, heterophil agglutination test, sedimentation rate, and agglutination tests for typhoid, paratyphoid, Brucella, and Proteus OX$_{19}$. Blood for cultures was drawn at noon, 4 p. m., 8 p. m., and midnight. A routine urine study was done, and urine for culture was taken.

The results of urinalysis, sedimentation rate determination, and blood cell count were reported as follows: urine: specific gravity 1.012, 8-10 leukocytes per high-power field, and other findings normal; hemogram: hemoglobin level 14 Gm. per 100 ml. (84%), red blood cell count 4,460,000 per cubic millimeter, and white blood cell count 6,100, with 31% segmented neutrophils, 4% monocytes, 6% stab cells, 1% eosinophils, and 58% lymphocytes (a rare atypical lymphocyte was seen); and sedimentation rate 8 mm. per hour (Westergren).

These findings tended to cast doubt on the diagnosis of active rheumatic fever and the existence of subacute bacterial endocarditis because of the absence of anemia and the lack of elevation of the sedimentation rate and the leukocyte count. Salicylates, however, will depress the sedimentation rate to some extent.[6]

The next day, two days after his admission, the temperature remained elevated and the pulse rate slow and the patient complained of pain in the left elbow which was tender on movement but was without redness or swelling. He appeared lethargic, but there was otherwise no change in physical findings. On this day the following laboratory reports were returned: heterophil agglutination positive in a 1:7 dilution, typhoid H agglutinin positive in 1:80 dilution, typhoid O agglutinin positive in 1:320 dilution, paratyphi A negative in all dilutions, Brucella abortus negative, and Proteus OX$_{19}$ negative. The blood culture taken at noon the previous day showed no growth. The 4 p. m., 8 p. m., and midnight specimens, however, showed a gram-negative bacillus. With this presumptive evidence of salmonella infection the patient was started on chloramphenicol (Chloromycetin) therapy.

The next day, three days after admission, the patient was still febrile and had rose spots on the abdomen and lower thorax anteriorly and the tip of the spleen was palpable. A second hemogram showed about the same hemoglobin level and red blood cell count, but the white blood cell count was 4,220 per cubic millimeter. Agglutination reactions at this time showed a rising titer of typhoid O agglutinins, which was now positive in a dilution of 1:640. Specific serum had established the diagnosis by a positive agglutination of the organism obtained on culture.

The next day the patient was transferred to the Essex County Isolation Hospital at the request of the board of health. Follow-up studies showed the titer for typhoid O agglutinin had risen to 1:800. Urine and stool cultures were, however, negative during the complete course of the disease, no doubt due to the specific treatment.

There were many questions that gave food for thought. Had the typhoid bacillus implanted itself on the damaged valves? After all, bacteremia and susceptible valves, the two conditions necessary for subacute bacterial endocarditis, were present. How long must treatment continue, and what are the accepted doses of chloramphenicol in this type of case?

Both answers were based on the treatment of typhoid itself rather than on the coexistence of the two diseases. In 18 days of treatment the patient had a total dosage of 33.5 Gm. of chloramphenicol. Stool cultures on three successive days after this treatment were negative, and the patient was then discharged as cured of typhoid. He has shown no sequelae after four years.

Comment

The differential diagnosis of prolonged fever in a patient with rheumatic heart disease includes not only active rheumatic fever and subacute bacterial endocarditis but also unrelated infectious diseases, collagen vascular diseases, neoplastic diseases, especially lymphomas, blood dyscrasias, and drug reactions.[7] This case demonstrates the need for a thorough diagnostic study in such patients before embarking on a program of prolonged treatment for subacute bacterial endocarditis without a positive culture.

It is interesting to note that subacute bacterial endocarditis and typhoid have many nonspecific features in common, namely, headache, malaise, chills, fever, cough, sweats, a skin rash, abdominal pain, palpable spleen, anemia, and arthritis or arthralgias. Definitive laboratory studies provide the differential diagnosis.

Summary

In a rare case, rheumatic heart disease was present with typhoid. Early diagnosis of bacteremia in patients with chronic rheumatic valvular disease is important.

ARTERENOL THERAPY FOR SHOCK AFTER ACUTE MYOCARDIAL INFARCTION AND PULMONARY EMBOLIZATION

Albert J. Miller, M.D.

and

Edgar A. Moser, M.D., Chicago

A study was made of the records of 55 patients who had severe shock after myocardial infarction and who were treated with either arterenol or metaraminol bitartrate. A distinct pressor effect was obtained in 42, shock was relieved in 38, and seven-day survival followed in 22. A similar study was made of 11 patients with shock after pulmonary embolism who received the same treatment. A distinct pressor effect was obtained in seven, shock was relieved in five, and seven-day survival followed in three. It is recommended that treatment with arterenol be started promptly after the recognition of shock in either type of patient. The simultaneous use of digitalis products in patients with coexistent congestive heart failure was not found harmful. To prevent local tissue injury, which caused sloughing in three cases, the bottle containing arterenol should be attached to the venoclysis apparatus only after a free flow has been established with a 5% solution of dextrose in water.

Arterenol (norepinephrine [Levophed]) is a naturally occurring substance which is the adrenergic nerve transmitter.[1] Kaindl and Lindner,[2] in 1950, and Liljedahl and Norlander,[3] in 1951, each reported its successful use in one patient with shock after myocardial infarction. Birke,[4] in 1952, published the results on three patients. In the United States, Miller and Baker [5] and Kurland and Malach [6] also presented their studies in 1952. These initial papers served to establish the relative safety of arterenol in the treatment of shock after myocardial infarction, and subsequently a number of other studies, some of which are summarized in table 1, have appeared.

In 1953, Miller and co-workers [7] reported the successful use of arterenol in two patients in shock after pulmonary embolization. Subsequently a few additional such patients were reported.[8]

It is now almost uniformly agreed that the therapy of choice for cardiogenic shock includes the use of vasopressor agents. An important impetus to this thinking was the report on mephenteramine by Brofman and associates.[9] In our view, arterenol is the vasopressor of choice when dealing with such a grave condition as severe shock after myocardial infarction, but its use needs considerable further clinical evaluation.

The present report summarizes a one-year experience of consecutively treated patients with cardiogenic shock at the Michael Reese Hospital, Chicago. Also, data on 11 additional patients with shock after acute pulmonary embolization are presented.

Methods and Criteria

The case histories of patients treated for shock with vasopressor drugs during a one-year period (August, 1956, to August, 1957) were collected. The records of the hospital pharmacy were used, and every patient who received arterenol or metaraminol bitartrate was noted. The hospital record was then reviewed and the data summarized.

From the Cardiovascular Department, Medical Research Institute, and the Department of Medicine, Michael Reese Hospital.

In this period, a total of 123 patients were treated for shock with arterenol, metaraminol, or both. Fifty-five of them fulfilled our criteria for having severe shock after myocardial infarction; 11 patients fulfilled similar criteria for shock after pulmonary embolization. The results in these two groups of patients form the basis of this report.

Our criteria to define severe shock are similar to those recommended by Binder and associates[10]: (1) systolic blood pressure 80 mm. Hg or less, (2) the presence of clinical signs of peripheral circulatory collapse, and (3) failure to respond to therapy which effectively relieved pain. However, in those patients known to have had hypertension previously, a systolic blood pressure of 90 mm. Hg or less was used instead. The pulse rate was not used in defining severe shock. We included patients with heart failure and arrhythmias and did not exclude those patients who died within one hour after therapy was started; the latter were analyzed separately.

In all instances, the diagnosis of acute myocardial infarction was confirmed by electrocardiogram or autopsy. The diagnosis of acute pulmonary embolus was made on clinical grounds, with electrocardiographic support and, in some instances, confirmation by autopsy.

A satisfactory pressor response was defined as a rise to a systolic blood pressure of 100 mm. Hg or higher. The shock was considered relieved if, after a satisfactory pressor response, the clinical signs of peripheral circulatory failure disappeared whether or not arterenol was still being administered. "Survival" was considered to have occurred when the patient lived for one week after arterenol therapy was discontinued. Note was made of patients who lived for 24 hours after therapy was instituted, whether or not arterenol was still being used.

Table 1.—*Reports of Arterenol Therapy for Shock After Myocardial Infarction*

1957	Littler, T. R., and McKendrick, C. S.: Lancet 2:825, 1957	22	10	..	0	22
	Total	158	126 (80%)	74 (46%)	57 (36%)	101 (64%)

Results

Shock After Myocardial Infarction.—The over-all mortality in the cases collected from the literature (table 1) was 64%. The over-all mortality in our present series was 60% (table 2). When the patients who received arterenol therapy for less than one hour before death are omitted, the mortality becomes 49%. This is close to that obtained by Sampson and Zipser[11] and represents a marked improvement over the known grave prognosis of cardiogenic shock not treated with vasopressor drugs.[12]

Table 2.—*Results of Arterenol Therapy in Fifty-five Patients with Shock After Acute Myocardial Infarction*

	No.	%
Pressor effect	42	76
Relief of shock	38	70
Survived		
24 hr.	31	56
Total	22	40
Died		
1 hr.	12*	22
Total	33	60
Frank congestive heart failure	13	24
Hypertension prior to shock	12	22
Auricular fibrillation	7	13
Atrioventricular dissociation	4	7

*Eleven were designated as "preterminal" on hospital chart and died within one-half hour after arterenol therapy was started.

The patients ranged in age from 44 to 91 years. Sixteen patients had a history of one previous myocardial infarction and two others of two such episodes. There was no significant difference in the results of treatment between those patients with and without a history of previous myocardial infarction. However, congestive heart failure significantly worsens the prognosis, as has been observed by others.[10] Thirteen patients had congestive heart failure; two of them survived.

The duration of shock, as expected, does influence treatment results. Three of 10 patients, in whom the shock was known to have been present for four hours or longer when treatment was started, survived. Ten of 17 patients treated when the shock was present for less than one hour survived. A history of previous hypertension did not significantly alter the results in our series.

All patients in frank congestive heart failure received one or another digitalis product. The results do not show any particular trend. In a number of instances the patients were not fully digitalized. In no case did the combination of digitalization and arterenol therapy appear harmful, an observation in keeping with our previous experience.[7]

Hydrocortisone was used in only four patients, with no demonstrable effect on the shock. Three of the 55 patients received metaraminol. No discernible effect was present in two patients; in the other, the blood pressure was adequately maintained subsequent to the relief of shock with arterenol.

In general, our experience in this series confirms previous observations[10] that the amount of arterenol administered per unit of time is of prognostic significance. However, two patients with satisfactory pressor responses to a modest dosage of arterenol subsequently were found to have massive myocardial infarction at autopsy.

Three of four patients with advanced atrioventricular block died. Five of the seven patients with auricular fibrillation died. All of the patients with auricular fibrillation received a digitalis product.

Shock After Acute Pulmonary Embolization.—The results of arterenol therapy for shock after acute pulmonary embolization are given in table 3. Five of the 11 patients were treated postoperatively. Five patients died less than one hour after the institution of arterenol treatment.

Complications.—Three of the 66 patients treated had superficial skin sloughs after infiltration by the arterenol solution. No skin grafting was necessary.

Comment

This retrospective study confirms the general opinion previously expressed in the literature, namely, that vasopressor therapy significantly improves the prognosis when shock complicates acute myocardial infarction. Manifest congestive heart failure plus shock remains a grave prognostic combination, and, when present, the results with arterenol are poor. A number of patients in our series were inadequately digitalized. Inasmuch as there appears to be no problem in using arterenol and digitalis products simultaneously, we strongly urge that digitalization should be adequate whenever congestive heart failure, even when slight in degree, is manifest. Indeed, the prognosis is in such cases so poor that rapid intravenous digitalization is probably advisable. Griffith and co-workers [12a] were unable to demonstrate a potentiating effect of hydrocortisone on the vasopressor action of arterenol when treating shock. Though we have noted no response in four patients, further investigation is necessary.

Table 3.—*Results of Arterenol Therapy for Shock After Acute Pulmonary Embolization*

Year	Author	Total No. of Patients	Pressor Effect, No.	Relief of Shock, No.	Survived, No.
1953	Miller and others [7]	2	2	2	2
1954	Wolff [8a]	1	1	1	1
1955	Sibthorpe [8b]	1	1	1	1
1955	De Swiet [8c]	1	1	1	1
Present study		11*	7	5	3
Total		16	12	10	8(50%)

* Five who died were treated less than one hour before death.

Shock after myocardial infarction should be treated as early as possible. Procrastination in instituting vasopressor therapy significantly decreases the survival rate. Indeed, serious consideration must be given to the use of vasopressors when hypotension persists after pain has been relieved. In such circumstances, the use of phenylephrine, mephentermine or metaraminol is satisfactory. When severe shock is present, the use of arterenol is preferred, since this drug's high potency is not matched by any other pressor agent. A substantial body of data indicates its high degree of safety. However, all potent vasopressor drugs should be used with caution in patients receiving vagal blocking drugs, since previous work from this department [13] has shown that arterenol administered under these circumstances may lead to supraventricular arrhythmias.

The use of arterenol has been criticized because it requires administration under constant medical supervision. However, patients in severe shock must be under constant medical surveillance irrespective of the therapy being used. In the presence of severe shock, intravenous therapy, insuring the immediate delivery of the drug, is obviously desirable.

Arterenol may cause local tissue injury, this being a reflection of its extreme potency as a vasoconstrictor agent. It is our impression that local tissue sloughs sometimes result from infiltration when the intravenous drip is being started. Accordingly, the bottle containing arterenol should be attached only after a free flow has first been established with a 5% solution of dextrose in water. Phentolamine (Regitine) hydrochloride should be injected locally whenever arterenol solutions infiltrate subcutaneously.[14]

No clear conclusions can be reached from the relatively few treated patients with shock after acute pulmonary embolization reported to date. Much further experience is needed in the use of vasopressor therapy. Certainly vasopressors merit consideration in this grave clinical condition.

Summary

A retrospective evaluation of arterenol (norepinephrine [Levophed]) therapy for shock after acute myocardial infarction and acute pulmonary embolization was based on a one-year experience at the Michael Reese Hospital, Chicago. Fifty-five patients with shock after myocardial infarction and 11 with shock after pulmonary embolization were studied. Arterenol was seen to be the therapy of choice in severe cardiogenic shock, and it significantly improves the prognosis. Manifest congestive heart failure along with shock after myocardial infarction remains a grave combination. Full digitalization, preferably by the intravenous route, should accompany arterenol treatment under these circumstances.

As with other forms of shock, the earlier treatment is begun the more effective it becomes. Hypotension persisting after the pain of acute myocardial infarction has been relieved may require treatment. Vasopressor drugs which can be administered subcutaneously or intramuscularly should be effective in most such instances. More data are needed on shock complicating pulmonary embolization before definite conclusions on the effectiveness of vasopressor therapy in this condition can be drawn.

BENIGN NEOPLASMS OF THE SMALL INTESTINE

WITH A REPORT OF THREE BLEEDING BENIGN TUMORS OF THE JEJUNUM

George W. Lechner, M.D.
and
Paul J. Connolly, M.D., Detroit

Three cases are described in which patients were hospitalized for massive intestinal bleeding. In each case the results of roentgenography were either negative or misleading, and the preoperative diagnosis was a probable bleeding duodenal ulcer, although the presence of tumor was considered. One patient also showed signs of intussusception. At laparotomy in each case the lesion proved to be a benign tumor, and excellent results followed resection. These observations are in accord with existing records of more than 1,400 cases of benign tumors in the small intestine. Many are asymptomatic, and less than 8% of all patients in whom such lesions were found by the surgeon had been given diagnoses before operation.

Although benign tumors of the intestine are admittedly uncommon, they can no longer be considered rare.[1] They are being reported with increasing frequency due to newer x-ray techniques, as well as to a greater awareness of their presence. The total number of documented cases exceeds 1,400. This does not include ectopic inclusions in Meckel's diverticula, aberrant tissues such as in the pancreas and gastic mucosa, hematomas, plasma cell myelomas, endometrial carcinomas, granulomas, inflammatory polyps, or carcinoids. With the exception of carcinoids, these are not true tumors, and the latter are of very questionable benignancy.

In most series, benign tumors of the small intestine are found to be less frequent than malignant ones, averaging 30 to 45% of the total.[2] In the younger age groups, however, the benign tumors apparently outnumber the malignant ones.[3] The malignant tumors occur in a somewhat older age group, the patients averaging 47½ years, as compared with 38 years for those with benign tumors.

Since the symptomatology of the benign lesions is frequently mild and nonspecific, the diagnosis is difficult to establish. Even when laparotomy is considered necessary, the preoperative diagnosis is seldom more than suspected. In symptomatic lesions, repeated laparotomies have, on occasion, been necessary before the lesion was discovered. Many tumors are found incidentally at surgery or at autopsy.

Many of the reports on smaller series state that the majority of benign tumors are found on postmortem examination.[4] However, the most authoritative review of the subject, by River, Silverstein, and Tope,[2c] reveals that in 72% of the 1,399 cases collected from the world literature through 1954 the tumors were removed at the time of surgery.

Etiology

The ultimate cause of most neoplasms is unknown, but the etiology of those in the small intestine is perhaps open to more speculation than elsewhere. Morison[5] commented in 1941 on the "remarkable immunity" of this region to neoplasms. This is despite the fact that the small intestine makes up 75% of the alimentary tract; it is more remarkable because the small intestine is preceded and followed by the stomach and colon, respectively, wherein 40% of all malignant growths originate. Less than 0.5% of all gastrointestinal carcinomas occur in the small intestine. Benign growths, however, are relatively more common; about 25% of the total benign gastrointestinal tumors occur in the small intestine.[6]

Numerous reasons for the low incidence of new growth in this region have been postulated. The most widely accepted of these hypotheses are (1) the alkalinity of the intestinal contents, (2) the minimum of stasis and kinking in this region, and (3) the diminished trauma due to the liquid nature of the fecal stream.[7] The etiological factor in certain cases apparently is hereditary, as evidenced by anobuccal melanosis (Peutz-Jeghers), neurofibromatosis (Recklinghausen's disease) involving the intestine, and certain cases of intestinal telangiectasia due to hemangiomatosis (Rendu-Osler-Weber) syndrome. In addition, certain other cases suggest a familial tendency. In some patients requiring multiple operations, the tumors are of different types, suggesting a low resistance to neoplasms.

According to River and co-workers,[2c] the sex incidence of these tumors is approximately equal, and the majority (60%) occur in persons between the ages of 30 and 60. However, almost 15% were in patients under 20, and about 0.1% of the total occurred in patients below one year of age.

Sarcoma is relatively more common than carcinoma. In fact, the majority of gastrointestinal sarcomas actually occur in the small intestine.[8] This suggests, perhaps, that sarcoma occurs somewhat as a happenstance, related more to the total length of the intestine exposed than to any specific etiological factor. This may also be true, to a lesser extent, of the benign tumors.

Pathology

Seventy-five per cent of the benign tumors of the small intestine, in their relative order of frequency, are adenomas, lipomas, myomas, polyps, fibromas, angiomas, or hemangiomas. It is noted that about two-thirds of the total originate from connective tissue.[2c]

The relative percentages of malignancy, as well as the incidence of all tumors, increase from the duodenum and jejunum to the ileum, being about 18, 25, and 57% respectively.[2c] These percentages are proportional to the lengths of the individual segments, although the jejunum may have somewhat less than its share.

The majority of benign tumors tend to be intraluminal, although they may be intramural or subserosal, depending on the site of origin.[4] As growth occurs in the intramural variety, they usually present as subserosal or intraluminal tumors. The majority of benign tumors are polypoid, although they may partially or completely encircle the intestine on occasion, as the malignant growths frequently do. Their polypoid nature accounts in part for the high incidence of intussusception with benign tumors, although this finding is uncommon with malignancy. The infrequency of intussusception with malignancy is also due to the greater induration and infiltration locally, preventing the intussusception from forming. The microscopic picture is frequently mixed in the case of connective-tissue tumors, particularly fibromas, although the epithelial lesions are usually more typical.[4]

Clinical Findings

As has been mentioned, many of the lesions never cause symptoms during life, or else the symptoms are so vague that the diagnosis is never established. The symptoms of duodenal and upper jejunal tumors frequently simulate disease of the stomach, duodenum, or pancreaticobiliary tract. Lesions of the ileum may suggest disease of the colon.[9]

The most common single condition leading to the diagnosis of benign tumors is intestinal obstruction. This is the presenting symptom in two-thirds of all cases, three-fourths of these being due to intussusception.[10] It is manifested by the usual symptomatology, with colicky pain, distention, constipation, and vomiting; if the obstruction is due to intussusception, there is frequently a palpable sausage-shaped mass and perhaps bloody mucus per rectum. This latter finding accounts for the fact that many of the cases were overlooked in earlier reviews, being lost in the voluminous literature on intussusception. In adults, the majority of all cases of intussusception are due to benign tumors of the small intestine, and such tumors should be intensively searched for whenever this type of obstruction is found at operation.[2c]

Frequently the tumor is not obvious at the time of operation, and often the intussusception has spontaneously reduced, leaving only a little dilated and edematous intestine to suggest the need for closer examination. These circumstances account for the frequent history of prior attacks, each typical of temporary mild obstruction. Numerous cases have been reported in which several explorations were required before the neoplasm was finally discovered.

Tumors of the ileum are more likely to cause intussusception than those of the duodenum, where intussusception rarely occurs. This is probably due to the semifixed nature of the duodenum and to the more solid consistency of the lower intestinal contents.[2c]

The next most common symptom is intestinal bleeding, usually manifested by anemia and/or melena. About one-third of the reported cases have presented in this way, with massive bleeding occurring in about 11%. Intussusception was a concomitant finding in half of the bleeding patients. Almost all of these patients had had numerous hospital admissions and diagnostic studies, without proper diagnosis. Massive bleeding carried with it an average mortality of 14%;[10] patients at times underwent several operations before removal of the lesion. Each of the patients here reported presented with moderate to severe upper intestinal hemorrhage; all had a history of prior episodes. One, in addition, had associated intussusception. Numerous other symptoms may occur on occasion, such as postprandial fulness, persistent or periodic epigastric pain, anorexia, and weight loss. None of these, however, is sufficiently specific to give much help in diagnosis.

Definitive diagnosis is difficult and, except in one or two series, has seldom been made preoperatively. In the most authoritative report, covering almost all the reported cases, the correct preoperative diagnosis was made in only 79 (7.8%) of the 1,014 instances in which a tumor was found at operation.[2c] The diagnosis was only suspected in the three cases reported below.

An increase in correct preoperative diagnosis has parelleled the improvement in roentgenologic techniques, and x-ray remains almost the only helpful aid in the diagnosis of benign tumors. The usual upper and lower gastrointestinal studies are rarely of much help except in excluding other diagnoses, although they may aid in revealing duodenal lesions. A negative gastrointestinal series should suggest the diagnosis in the presence of melena especially when it is massive and without hematemesis. Such a situation was present in two of our cases. In the other there was some dilation of the duodenum above an obstruction that was found later to be due to intussusception.

Detail films of the small intestine, when properly done, may be of considerable value in diagnosis[11] (although in our cases they were not), particularly when made with the aid of an inlying Miller-Abbott tube. Thin barium may be injected through the tube when the balloon is stopped by the lesion. Despite the time and effort required, these special studies should be utilized in properly selected cases. If this were done, up to 50% of these cases could be diagnosed preoperatively.[12]

Treatment

The treatment of benign tumors of the small intestine is essentially surgical and is directed at total removal by the simplest method. There should be intensive preoperative treatment of the associated anemia, electrolyte disturbances, and dehydration.

If small, tumors frequently may be removed by enterotomy and either ligation at the base of the pedicle, when feasible, or diamond-shaped submucosal excision. If the tumor is larger, a limited resection with end-to-end anastomosis is usually carried out. Rarely are benign tumors of such size or location as to require more complicated treatment.

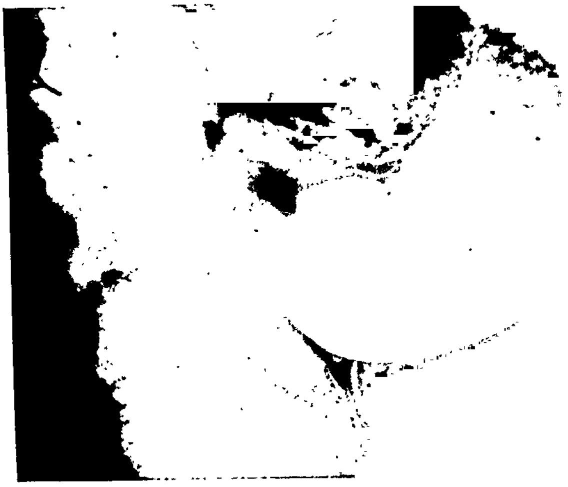

Fig. 1.—Dilated stomach and duodenum with little barium in fourth part of duodenum and none beyond duodenum.

Despite the desirability of preoperative antibiotic preparation of the intestines, most excisions have been carried out without this, with relatively good results. Tabulated results in 960 cases in one series where statistics were available, gave an over-al operative and postoperative mortality of 20.6% There has been a steady decline in mortality ove the past 20 years.[2c]

Presented below are reports on three benig jejunal tumors encountered in the practice of on of us (P. J. C.), two of them within the past yea

Report of Cases

Case 1.—A 57-year-old man was admitted on Jan. 1 1953, with the chief complaints of epigastric pain and tarr stools, both present for about three weeks. The pain in th epigastrium was described as gnawing in nature, occurrin usually when the patient was hungry and at times noctu nally. It radiated around both costal margins to the back.

was relieved by food and milk of magnesia. Simultaneously he had developed melena, which persisted in all stools. Four days prior to admission he was seen in the hospital emergency room and given medication because the pain had kept him awake. He complained of weakness during the previous week but denied syncope. There was no known weight loss, no hematemesis or other vomiting, and no diarrhea or hematochezia. He denied pyrosis and meteorism, and the gastroenterological inventory was otherwise negative, as was the remainder of the history.

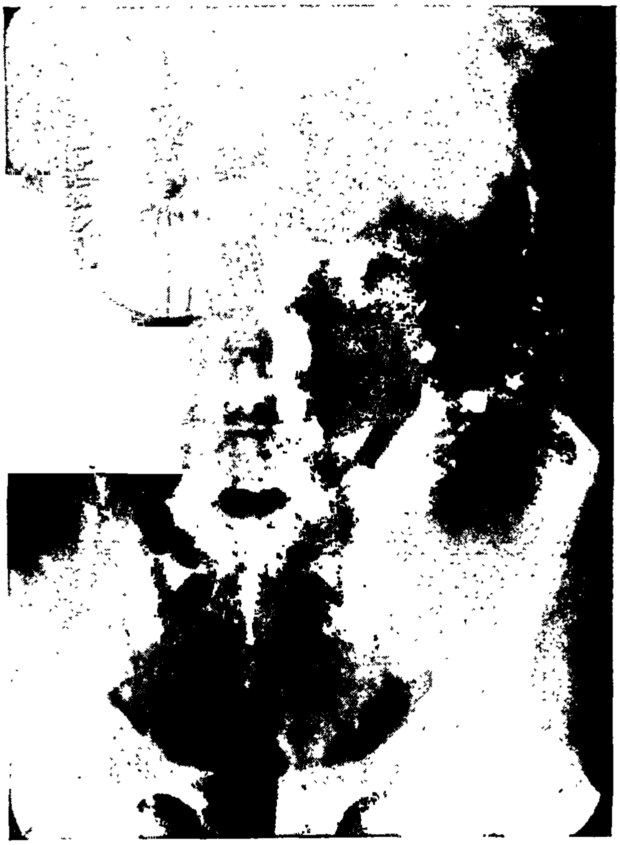

Fig. 2.—Almost complete obstruction at duodenal-jejunal junction with only trickle of barium in upper jejunum.

Three to four years earlier he had had similar pains associated with melena and was seen in another hospital, where a gastrointestinal series was reported negative. He was given a transfusion and placed on a diet for ulcers, but he discontinued this when the symptoms abated.

The patient was well developed and well nourished. He had a blood pressure of 140/80 mm. Hg, a pulse rate of 92 per minute, full and regular, and a respiratory rate of 20 per minute. The skin showed marked pallor but was dry and warm. Examination was otherwise entirely negative. The diagnosis on admission was bleeding duodenal ulcer.

Laboratory studies disclosed a hemoglobin level of 6.6 Gm. per 100 cc., a red blood cell count of 2,810,000 per cubic millimeter, and a color index of 0.77. There was marked anisocytosis and moderate hypochromia. The white blood cell count was 8,300 per cubic millimeter, with a normal differential; urinalysis was negative. Blood chemistry studies gave essentially normal results. Two days later the hemoglobin level had risen to 10.2 Gm. per 100 cc. after transfusions. There were 6.8% reticulocytes, and the platelet count was 725,000 per cubic millimeter. X-rays taken on this day revealed a complete obstruction of the third and fourth portions of the duodenum, with 100% gastric and duodenal retention at three hours (fig. 1 and 2). Studies with the barium enema gave negative results. After the upper gastrointestinal series had been completed, complete obstruction occurred. Levin tube suction was begun, and he was given fluids and blood, receiving a total of six units preoperatively, which maintained the hemoglobin level slightly below normal.

The patient was operated on eight days after admission, with the preoperative diagnosis of probable malignant duodenal tumor. Surgery revealed an intussusception about 14 in. in length, extending up to the ligament of Treitz. This was reduced by traction and pulsion. A dimpling of the wall of the jejunum was noted about 12 in. distal to the ligament, and a polyp was palpable, with a large lymph node nearby. Results of frozen section of the node were not satisfactory, so a wedge resection, including the mesenteric nodes, was done, followed by open end-to-end anastomosis. The polypoid tumor (fig. 3) proved to be a lipoma, with mucosal ulceration over the tumor. The postoperative course was uneventful, and the patient was discharged after eight days.

Case 2.—A 42-year-old woman was admitted to the hospital on Jan. 6, 1957, with the chief complaint of anemia. She had been well until one year pior to admission, when she had had a series of tarry stools without abdominal pain, hematemesis, or other gastrointestinal symptoms. She was admitted to a hospital in another city, where x-rays and sigmoidoscopic examination were reported negative. She received three units of blood and was placed on a diet for ulcers, plus iron medicaments, and was discharged.

Six months prior to the present admission she had again had a series of tarry stools associated with weakness and easy fatigability. This lasted three weeks and was associated with occasional vague abdominal discomfort unrelated to food. She was very pale on admission and her hemoglobin level was 3.2 Gm. per 100 cc., with a red blood cell count of 1,700,000 per cubic millimeter. She had 4+ occult blood in the stool, and the other laboratory studies showed normal results. She was given transfusion until her hemoglobin level reached 11.9 Gm. per 100 cc.; seven units of blood was required. A complete gastrointestinal series, including detail

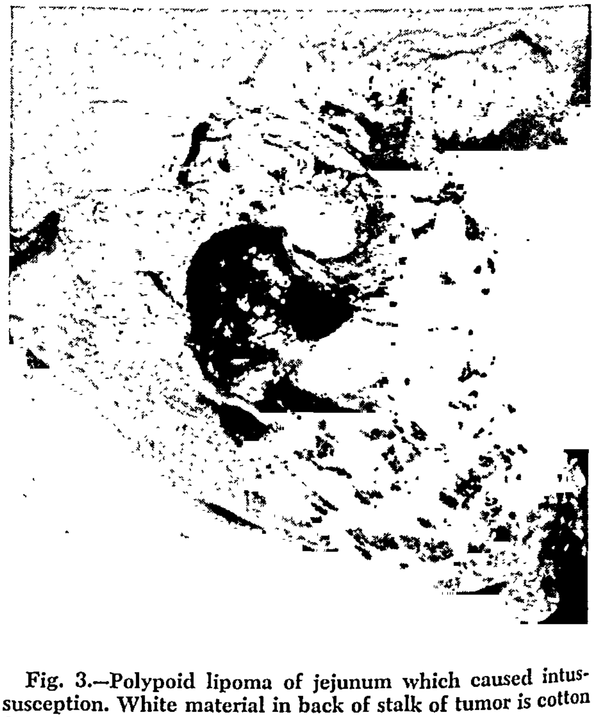

Fig. 3.—Polypoid lipoma of jejunum which caused intussusception. White material in back of stalk of tumor is cotton for photographic contrast.

studies of the small intestine, was negative. The string test was positive for blood in a localized area, 56.25 cm. from the incisors, the pylorus being estimated at 54 cm. Gastroscopic examination was refused, and she was discharged on an ulcer diet after the bleeding had apparently stopped.

The most recent admission was because a periodic examination had revealed that the hemoglobin level was again down, this time to 8.0 Gm. per 100 cc. It had been normal on previous examinations, and the patient had no melena or other symptoms, except for a loss of 20 lb. (9.1 kg.) during the previous year. She had remained on her diet. Her medical and social history, as well as the systemic review, were negative, except for a history of hypertension five to six years earlier.

The patient was obese, and her skin was quite pale. The blood pressure was 130/75 mm. Hg, and the white blood cell count and urinalysis were normal, as were the prothrombin time and platelet count. The stool contained 4+ occult blood. X-rays were again normal. The string test revealed blood staining from what was thought to be the cardia to the pylorus. Administration of six units of blood was required over a two-week period to maintain the hemoglobin at near normal levels. A diagnosis of probable duodenal ulcer was made, and operation was scheduled for Jan. 22, 1957. A polypoid tumor (fig. 4, 5, and 6) of the jejunum was removed by simple wedge resection from the antimesenteric border. The patient's course was satisfactory, and she was discharged on the seventh postoperative day. The pathological diagnosis was "fibroma with ulceration."

Case 3.—A 53-year-old woman was admitted on Nov. 20, 1957, with the chief complaint of black stools for the previous three days. She gave a history of recurrent episodes of melena over a 24-year period; these attacks had occurred every few months and had lasted an average of one to three days. She had been anemic for years, the hemoglobin level being 8.9 Gm. per 100 cc. on one known occasion. The most recent attack had consisted of frequent melanotic stools, occurring several times daily. Several of them also contained bright red blood. She had been dizzy and weak during the previous 24 hours and had had an episode of syncope the evening of admission. Several of the prior bleeding episodes had been massive, requiring transfusions. The patient denied ever having had any abdominal pain, pyrosis, meteorism, or hematemesis. She had previously had numerous gastrointestinal x-rays, and all except one were normal. This one, taken several years before, apparently had revealed a duodenal ulcer. The patient said she had been easily bruised for years, but a complete hematological study two months prior to admission was entirely normal.

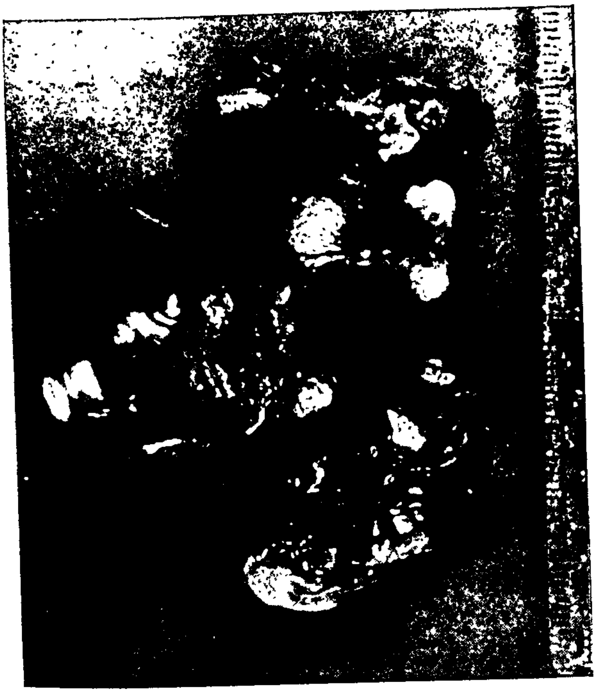

Fig. 4.—Fibroma of jejunum. Segment was removed at operation.

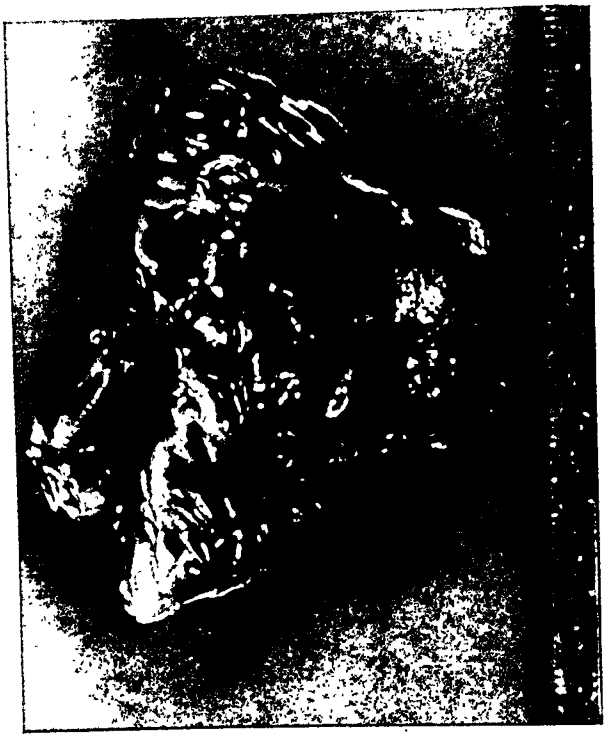

Fig. 5.—Jejunum opened showing ulceration of fibroma with drop of blood coming from ulceration.

During an examination for a bleeding episode one and one-half years prior to this admission, a completely asymptomatic adenocarcinoma of the right kidney had been discovered on pyelography. This was removed uneventfully, with no subsequent symptoms. The history and systemic review were otherwise noncontributory.

The patient was well developed and well nourished, but she appeared quite pale. Her blood pressure was 112/68 mm. Hg, pulse 116 per minute, and respiratory rate 20 per minute. Minimal epigastric tenderness was noted by one examiner, as well as a positive tourniquet test when blood was drawn for typing. The physical examination was otherwise negative. The tentative diagnosis was bleeding peptic ulcer, with blood dyscrasia and metastatic adenocarcinoma to be ruled out.

The hemoglobin level was 6.8 Gm. per 100 cc. on admission, and the white blood cell count was 12,500 per cubic millimeter, with a normal differential. The microhematocrit reading was 25%, urinalysis was negative, and stool examination was repeatedly positive for occult blood. The upper gastrointestinal x-ray series, chest x-ray, and bone survey were negative. Seven transfusions over an eight-day period maintained the hemoglobin level at only 6 to 8 Gm. per 100 cc., finally bringing it up to 12 Gm. prior to operation. This was despite intensive ulcer therapy.

Operation was carried out on Dec. 4, 1957, and revealed a polypoid lesion in the jejunum, 11 in. from the ligament of Treitz. This was removed by wedge resection with end-to-end anastomosis. There was no evidence of tumor in the left renal area. The pathological report was leiomyoma of the jejunum. The postoperative course was entirely satisfactory, the patient being discharged after eight days.

Summary and Conclusions

Benign tumors of the small intestine can no longer be considered rare, since the total reported cases exceed 1,400. They are being reported with more frequency, particularly as newer x-ray techniques for studies of the small intestine have been developed.

Although many cases are asymptomatic and are found incidentally at operation or at autopsy, of all the documented cases, 70% were found at operation and a considerable percentage of these were symptomatic. Less than 8% of all patients operated on have been given diagnoses before surgery. This figure could be raised to nearly 50% by proper x-ray examination, and a few series have approached this figure.

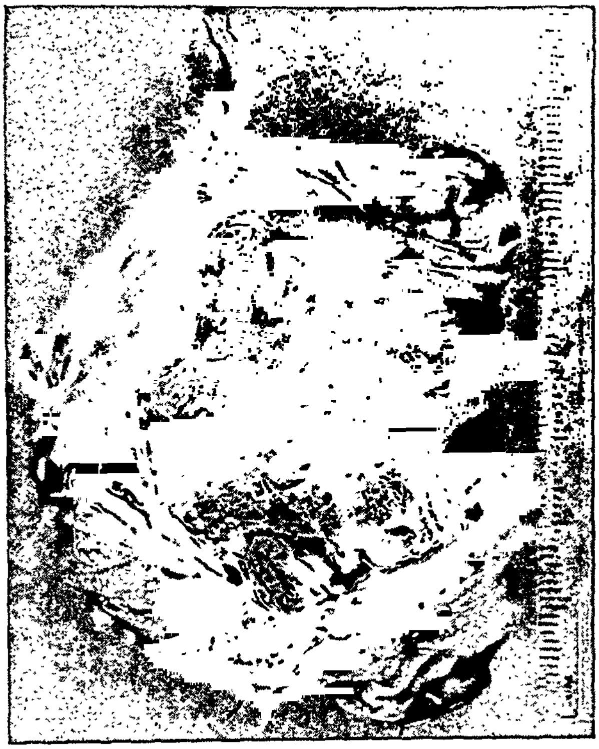

Fig. 6.—Tumor sectioned to show fibrous character.

Most series show benign tumors to be less frequent than malignant, and they are also less apt to be symptomatic. The etiology is essentially unknown. The sex incidence is equal, and the majority of these tumors occur in patients between 30 and 60 years of age. One-half of all cases occur in the ileum, the duodenum being the rarest location.

Most benign tumors are polypoid, and the most common presenting symptom is obstruction. The majority of these obstructions are due to intussusception. In fact, the majority of cases of intussusception in adults are due to benign tumors of the small intestine. The second most common symptom is bleeding. Diagnosis in the case of massive bleeding is usually late, and the mortality is fairly high. Tumor of the small intestine should be considered in patients with upper gastrointestinal bleeding without hematemesis in whom the upper gastrointestinal x-rays are negative.

Treatment is surgical and is directed at the simplest method of removal, usually either enterotomy with simple excision or resection with end-to-end anastomosis. The results have been relatively good, although the over-all mortality is about 20%; there has been a marked decline in recent years.

In the three cases of benign jejunal tumors reported here, all patients were admitted with massive upper intestinal bleeding. One of them also had obstruction due to intussusception. Preoperative diagnosis in all cases was probable bleeding duodenal ulcer, although the presence of tumor was considered. Upper gastrointestinal x-rays in all cases were either negative or misleading, including a series of the small intestine in one instance. Excellent results followed resection in all our cases.

AGED INFIRM RESIDENTS IN A CUSTODIAL INSTITUTION

TWO-YEAR MEDICAL AND SOCIAL STUDY

Eugene Moskowitz, M.D., Mount Vernon, N. Y., Edith R. Fuhn, B.S., Valhalla, N. Y.,
Margaret E. Peters, M.P.H.
and
Allan S. Kearley, M.B., New York

The feasibility of a method of disability evaluation in aged infirm people was tested in a group of 115 residents of a custodial institution. They were observed over a period of two years, at the end of which time about half of those remaining in the institution were over 75 years of age. A continuous process of rehabilitation was shown to be necessary in these patients. It involves restoration, reactivation, and maintenance and is especially important in those who have been admitted from a hospital or are temporarily hospitalized during their residency. There is a tendency for them to continue at the low level at which they were functioning when discharged from the hospital. This is a major problem in a domiciliary institution. Its solution requires the cooperation of the family and the community. Periodic disability evaluation and assessment of the patient's resources are essential. During the period of the study seven residents were discharged from the county home to their community.

A selected group of 115 aged, infirm individuals were thoroughly screened in order to serve as the basis for a determination of the feasibility of a method of disability evaluation. This system was subsequently called the "Physical Profile (PULSES)" and has been described previously.[1] The objective was to develop a method for expressing the ability of an aged, infirm individual to perform routine physical activities within the limitations imposed by various physical disorders.

This study deals with a two-year review of the same group of patients, with use of similar medical and social techniques to evaluate their problems. All the individuals were residents of a county home, living under similar conditions, with careful control of their medical problems by the same personnel throughout the entire two-year period of observation. In addition, an adjacent county hospital was available for all acute surgical and medical care, and complete diagnostic and laboratory facilities were available. Complete records were kept on all patients, and the hospital charts were thoroughly reviewed. Reexaminations were carried out at periodic intervals, averaging not more than three months, and a new physical profile was assigned each patient to indicate his functional capabilities. The residents received comprehensive medical care, including physical rehabilitation services provided by the county hospital. Social service was provided by the staff of the home on an on-going basis.

During the two-year period there were 36 deaths, constituting 31% of the entire group. It is rather significant to note that there was only one postoperative death. Pulmonary complications accounted for one-third of the deaths; these included five cases of pulmonary emboli, none of which were postoperative. The major cause of death was cardiac in 10 patients (coronary occlusion in 8 and congestive heart failure in 2), pulmonary in 12 (bronchopneumonia 6, pulmonary embolus 5, and pulmonary hemorrhage 1), cerebral in 4 (cerebrovascular accident 3 and parietal meningioma 1), urinary tract infections in 5, gastrointestinal in 2 (intestinal obstruction 1 and perforated duodenal ulcer 1), and miscellaneous in 3. All but one of the patients died in the hospital; the terminal illness was less than 10 days in 66% of the cases.

Of the 79 individuals surviving the two-year period, 25, or 32%, required varying periods of hospitalization, with a total of 38 admissions. The medical causes for hospitalization included pulmonary infection 7, urinary tract infection 5, control of diabetes 4, and cerebrovascular accident 2. The surgical causes included trophic and stasis ulcer 6, amputation of the lower extremity 3, cataract 3, disease of the urinary tract 3, hip fracture 1, carcinoma of the esophagus 1, and miscellaneous 3. There was only one hip fracture in the entire group. Peripheral vascular disorders involving the lower extremities were a frequent cause for hospitalization. One patient with an inoperable carcinoma of the esophagus was the only patient hospitalized for a malignancy. The relatively low

incidence of urinary tract surgery is explained by the fact that several male residents had a prostatic resection prior to their admission to the home.

The Resident

At the end of the two-year period, 71.4% of the residents were at a level of complete independence, either in a wheel chair or on an ambulatory basis. In addition, four individuals were transferred to noninfirmary sections of the home where they did not require any supervision in their care. Seven were discharged from the county home to the community, and five were subsequently revisited in their own homes. In each instance, it was obvious that the individual had improved in the home situation, and there were no requests for readmission to the county home. This substantiates observations previously made in another study,[2] where it was established that once the pattern of rehabilitation had been set it continued within the home, guided by the proper motivation of interested relatives. Undoubtedly, this could be accomplished in more instances if community attitudes were changed.

Marital Status of Residents in a Custodial Institution

	Male	Female	Total
Single	30	12	42
Widowed	25	29	54
Separated	5	4	9
Divorced	4	..	4
Married	4	2	6
Total	68	47	115

Despite all efforts, nine residents underwent progressive physical deterioration ultimately necessitating complete nursing care. These patients constitute what may be termed the hard-core nursing problem in any domiciliary institution for the aging. Four individuals were transferred to psychiatric institutions when their mental problems could not be controlled in the domiciliary setting. However, there were many other marginal patients who were able to make the necessary adjustment to the sheltered setting in the county home. Some of these residents had previously been certified for transfer to psychiatric facilities.

Of the 115 residents in this survey, 56 (49%) were admitted from hospitals and nursing homes; 33 of these came directly from the adjacent county hospital, 16 from voluntary hospitals, and 7 from nursing homes. Fifty-nine residents (51%) came directly from the community; 16 were from a room and board facility, 27 from their own home or apartment, and 10 from a home with relatives; 6 were transient males.

The marital status of this group is illustrated in the table. Ninety-four per cent of the group had been living in a single status. Seventy-four persons were self-sufficient financially, through personal savings, odd jobs, and various types of pensions and other remuneration such as social security. Public assistance was rendered to 41, or 36%, as their sole method of community maintenance. A study of the occupational histories revealed that the majority of these individuals came from the unskilled, nontechnical categories. There were no professional people in this group. However, there were five white collar workers.

The age distribution of those individuals still remaining in the county home at the end of the two-year period is as follows: age 45 to 49, 1 person; age 50 to 54, 3; age 55 to 59, 6; age 60 to 64, 5; age 65 to 69, 13; age 70 to 74, 3; age 75 to 79, 7; age 80 to 84, 13; age 85 to 89, 6; age 90 to 94, 4; and age 95 to 99, 2. Almost 51% are over 75 years of age.

During the two-year period of observation, there were transitions in the physical profile of many residents. They reflected changes in their physical status without necessarily any alteration in their medical diagnoses. Some individuals improved, others became worse, and many maintained their physical and mental status. In addition, others underwent deterioration after acute illness and subsequently required assistance in returning to their previous functional level. This was termed reactivation in contrast to physical restoration. The latter term was applied to the rehabilitation of those residents who had incurred disabilities primarily involving the neuromuscular or musculoskeletal systems, such as a stroke or a fractured hip. However, it should be noted that the rehabilitation process was, of necessity, an on-going program, for it was equally important to maintain many of these patients at the maximum functional level which had been achieved, either in their reactivation or in their physical restoration program. This previously described program[2] has been termed a maintenance type of physical rehabilitation; it has been described also by Costello and Tanaka.[3] At the end of the two-year period of observation, 54% of the remaining patients were considered to be on such a maintenance program.

Comparison of the various components of the physical profile again substantiates the original findings, namely, a preponderance of disabilities involving the lower extremities which underwent the greatest deterioration. This is illustrated in the figure. In contrast, the upper extremities showed very little change during this same period. As anticipated, the incidence of incontinence increased, but there were only four totally incontinent patients at the end of the two-year period among those who had survived.

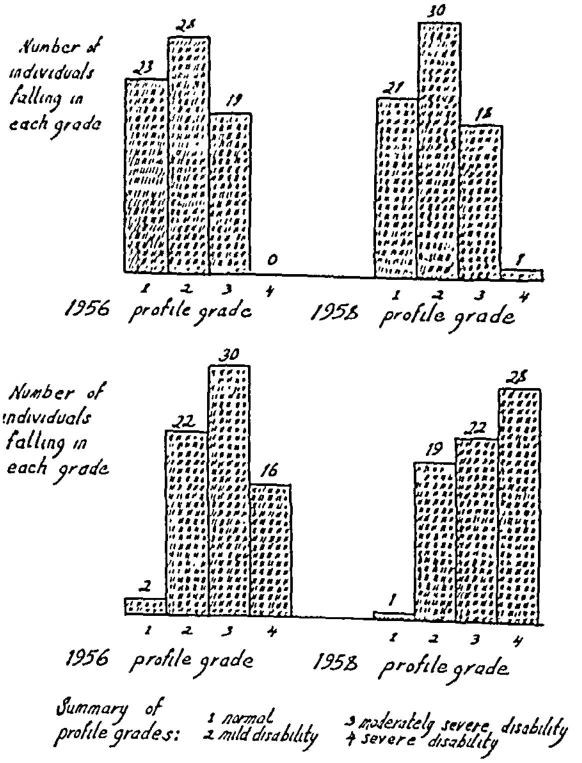
Rehabilitation Program

The introduction of a physical rehabilitation program in a county home more than three years ago has gradually crystallized a new concept in custodial care. The aging resident frequently becomes chronically ill and infirm. Rather than requiring pure domiciliary care on an ambulatory basis, these people need adequate medical and social services to meet their daily on-going needs as they arise. There is an increasing tendency to consider these domiciliary institutions as points of no return, not only from the medical but from the sociological perspective as well. While these individuals are, of necessity, housed in an institution devoted to the care of this type of patient, it does not necessarily follow that they should not be exposed to the same general medical and rehabilitation concepts which are carried out in the community. A bedridden individual in a domiciliary institution constitutes the major problem in nursing care. It is therefore necessary to be on the alert for comparatively minor defects which could ultimately lead to increasing this problem.

Originally, the physical profile was developed as a guide for those concerned with the care of the domiciliary patient. It enables them to estimate roughly the physical and mental abilities of any person. Periodic reevaluation enables one to determine exactly what is happening to the person. The physical rehabilitation program is geared to the specific needs of the individual at any one particular time. It has been recognized that the patient may undergo physical and mental deterioration without any changes from the diagnostic point of view. Teaching an individual to walk to the bathroom can influence his dietary habits as well as his mental attitude and behavior in the area where he is domiciled. Most elderly people have a tendency to take to a chair or to other sedentary activities, and an organized program of activity is vital for maintaining their physical capabilities. Contractures in the lower extremities, particularly the hips and knees, are very prone to develop from protracted sitting. A mild contracture may make the difference between an ambulatory and wheel chair existence. Periodic reevaluation of these individuals, with an estimate of their capabilities as reflected in the physical profile, immediately calls attention to these changes and initiates the proper corrective measures.

As previously noted, many individuals were hospitalized for intercurrent infections or other medical and surgical complications, and it was necessary to reactivate them after these illnesses. This is one of the major problems in a domiciliary institution. There is a tendency for them to continue at the level at which they were functioning at the time of discharge from the hospital. This is particularly true of individuals who are transferred from voluntary hospitals where the facilities are limited for any type of activation program. They are transferred soon after the termination of the acute phase of the illness, but this does not imply maximum physical restoration.

From the social point of view, it is equally important to change the concept of the domiciliary institution. It has been extremely difficult to work with relatives in making adequate plans for possible discharge of those who have improved during the course of their institutional care. In those instances where there is any hope of further rehabilitation, it is necessary to maintain an on-going casework service in order to make the family understand that there exists the possibility of improvement in the resident in a custodial institution, with the ultimate goal of return to the community.



Comparison of upper (*above*) and lower (*below*) extremity profile gradings in 70 patients in 1956 and 1958.

However, it should be recognized that in any domiciliary institution there are a given number of patients who require complete, permanent nursing care. By making more individuals self-sufficient, it should not be assumed that one can reduce the cost of domiciliary care. It does enable a greater allocation of manpower to those persons who require complete care. This recognizes the fact that no domiciliary institution can easily recruit and maintain a complete staff at all times.

Summary and Conclusions

In a two-year study of 115 aged, infirm individuals, a system of disability classification, termed the "Physical Profile," served as an effective index for recording the physical and mental status of the patients. The rehabilitation of a domiciliary patient is a continuous process involving restoration, reactivation, and maintenance, with transitions from one phase to another to meet the changing needs of the individual. Various disabilities affecting the lower extremities constituted the major factor in loss of rehabilitation potential. The terminal illness, averaging less than 10 days in 66% of the deaths, was the major cause for hospitalization in this domiciliary group. The changing population of domiciliary institutions requires a careful screening and follow-up program for recognition of the convalescent or deteriorating aged, infirm individual who can benefit from an organized activity program.

CHRONIC GASTRITIS

HISTOLOGICAL CRITERIA FOR MANAGEMENT AND MEDICAL TREATMENT WITH A MUCOSAL ANESTHETIC IN ALUMINUM HYDROXIDE

Emmanuel Deutsch, M.D.
and
Howard J. Christian, M.D., Boston

Gastroscopy with multiple biopsies shows that in severe chronic gastritis the mucosal pattern is distorted by irregular distribution of the gastric glands, increased numbers of mucus-secreting cells, and inflammatory infiltration of the stroma. The pattern of symptoms (pain-food-pain cycle) and failure to respond to antacids also distinguish chronic gastritis from the typical peptic ulcer. Ninety-two patients with chronic gastritis were treated with bed rest, sedatives, gastric suction, meals planned not to exceed the patient's critical volume, and a combination of aluminum hydroxide gel with oxethazaine hydrochloride, a topical anesthetic. While the severe forms of chronic gastritis were refractory to this treatment, the moderate and mild forms proved amenable, and the combination of antacid and anesthetic afforded relief from pain for periods up to six hours after each dose. Medication was continued for six days to 18 months without evidence of significant side-effects.

In planning an adequate program for treatment of chronic gastritis, a satisfactory method is urgently needed with which to obtain objective evidence for correlation with the clinical symptoms of gastric inflammation. The use of gastroscopy[1] and multiple biopsies has enabled formation of a definitive plan for management of the problem. Criteria for evaluation of the histological picture are suggested in table 1. This is especially useful in the large number of dyspeptic patients for whom the roentgenogram is negative.

Traditional treatment of chronic gastritis has paralleled that of peptic ulcer, but the pain pattern is usually quite different. In ulcer the characteristic sequence is pain-food-relief; in gastritis, pain-food-pain. Upper abdominal distress and bloating after meals are the commonest complaints. Nausea and vomiting become more prominent as illness is prolonged. Weight loss may reach 40 to 80 lb. (18.1 to 36.3 kg.) in the severe form. Achlorhydria is noted in 10 to 15% of cases. The standard ulcer regimen —diet, antacids, and anticholinergics—usually fails to relieve symptoms of gastritis.

Classification of Gastric Histology

Normal.—Normal human gastric mucosa presents a compact and regular glandular pattern. The glands contain one to three parietal cells and the remainder are chief cells in a symmetrical placement around the circumference. Mucus-secreting cells are generally insignificant. The stroma is

---

From the departments of medicine and pathology, Carney Hospital and Tufts University Medical School.

Based on a paper read before the 11th Clinical Meeting of the American Medical Association, Dec. 6, 1957, Philadelphia.

sparse because of the compact glandular structure. The muscularis mucosae is thin and uniform without evidence of scarring or inflammatory infiltrate. The vessels throughout the sections are generally inconspicuous (see figure, *A*).

TABLE 1.—*Criteria for Histological Evaluation of the Gastric Biopsy*

- General architecture
  - Mucosa normal or showing inflammatory lesions (gastritis)
  - Tumor
- Epithelium and glands
  - Normal
  - Abnormal
    - Individual cell character and inflammatory change
    - Absence of acid cells
    - Intestinalization—excessive production of mucus
    - Cystic change in glands
    - Evidence of injury and repair
    - Mitotic activity, tendency toward reversal of nucleus-cytoplasm ratio
- *Stroma*
  - Interstitial infiltrate
    - Extent—cells per high-power field
    - Character of infiltrating cells
    - Lymphoid aggregates with and without germinal centers
- Muscularis mucosae
  - Normal
  - Abnormal
    - Cellular infiltrate
    - Edema
    - Hypertrophy
    - Evidence of injury and repair—scarring, glandular elements
- Congestion of vessels

Mild.—In mild chronic gastritis the glandular pattern is not significantly altered. Small numbers of inflammatory cells (lymphocytes and plasma cells) are haphazardly distributed throughout the interstitial tissue, with occasional slight displacement of the glands. The muscularis mucosae generally is uninvolved by this process (see figure, *B*).

Moderate.—In moderate chronic gastritis the mucosal pattern is moderately distorted with irregular distribution of the individual glands. Early intestinalization of the surface epithelium is present. The interstitial infiltrate is increased and more uniform in distribution, with formation of discrete lymphoid follicles. Some disruption of the muscularis mucosae is seen secondary to extension of the inflammatory process from the mucosa (see figure, *C*).

Severe.—In severe chronic gastritis there is considerable distortion of the mucosal pattern owing to compression and asymmetrical distribution of the glands. Increased numbers of mucus-secreting cells indicate a definite conversion to colonic-type epithelium. The stroma contains a heavy inflammatory infiltrate with many lymphoid follicles, some with active germinal centers. Fragmentation of the muscularis mucosae is seen secondary to inflammation and fibrosis (see figure, *D*).

Present evidence [2] suggests that mesenchymal cells may be unicellular endocrines which produce histamine, heparin, hyaluronic acid, and serotonin. In time of stress these may react as part of the mesenchymal system. This system includes fibroblasts, mast cells, and basophils. The chronic inflammatory infiltrate which seems to be a prominent part of the picture in gastritis may also participate in the functioning of the mesenchymal system.

The mechanism underlying the frequently described feeling of fulness and bloating may possibly involve the presence of gastric stretch receptors in the muscularis mucosae and their vagal afferent fibers, as suggested by the experiments of Paintal [3] in cats and of Towbin [4] in dogs. Towbin's experiments suggested that the reflex pathway lies in the vagus. The reflex arc consists of the gastric stretch receptor, vagal fibers, and the midbrain.

It is conceivable that in the presence of chronic inflammation of the stomach, such gastric receptors will respond to a smaller than normal volume of fluids and food, with immediate satiation of thirst and hunger. On increase of the water or food intake above this level (critical volume), gastric distress develops:

Inhibition of Histamine-Stimulated Gastric Acid

Many investigators have studied the role of the gastric antrum in controlling gastric secretion.[5] It is believed that in dogs in which the Heidenhain pouch has been established, the antrum, if exposed to or distended by food with a pH of 3.0 or above, releases gastrin to stimulate secretion in the pouch. In the presence of greater acidity, no secretion is stimulated. In the fasting state, the Heidenhain pouch yields no free gastric acid.[6]

TABLE 2.—*Diagnosis in Ninety-two Patients Examined and Treated for Inflammatory Gastric Lesions*

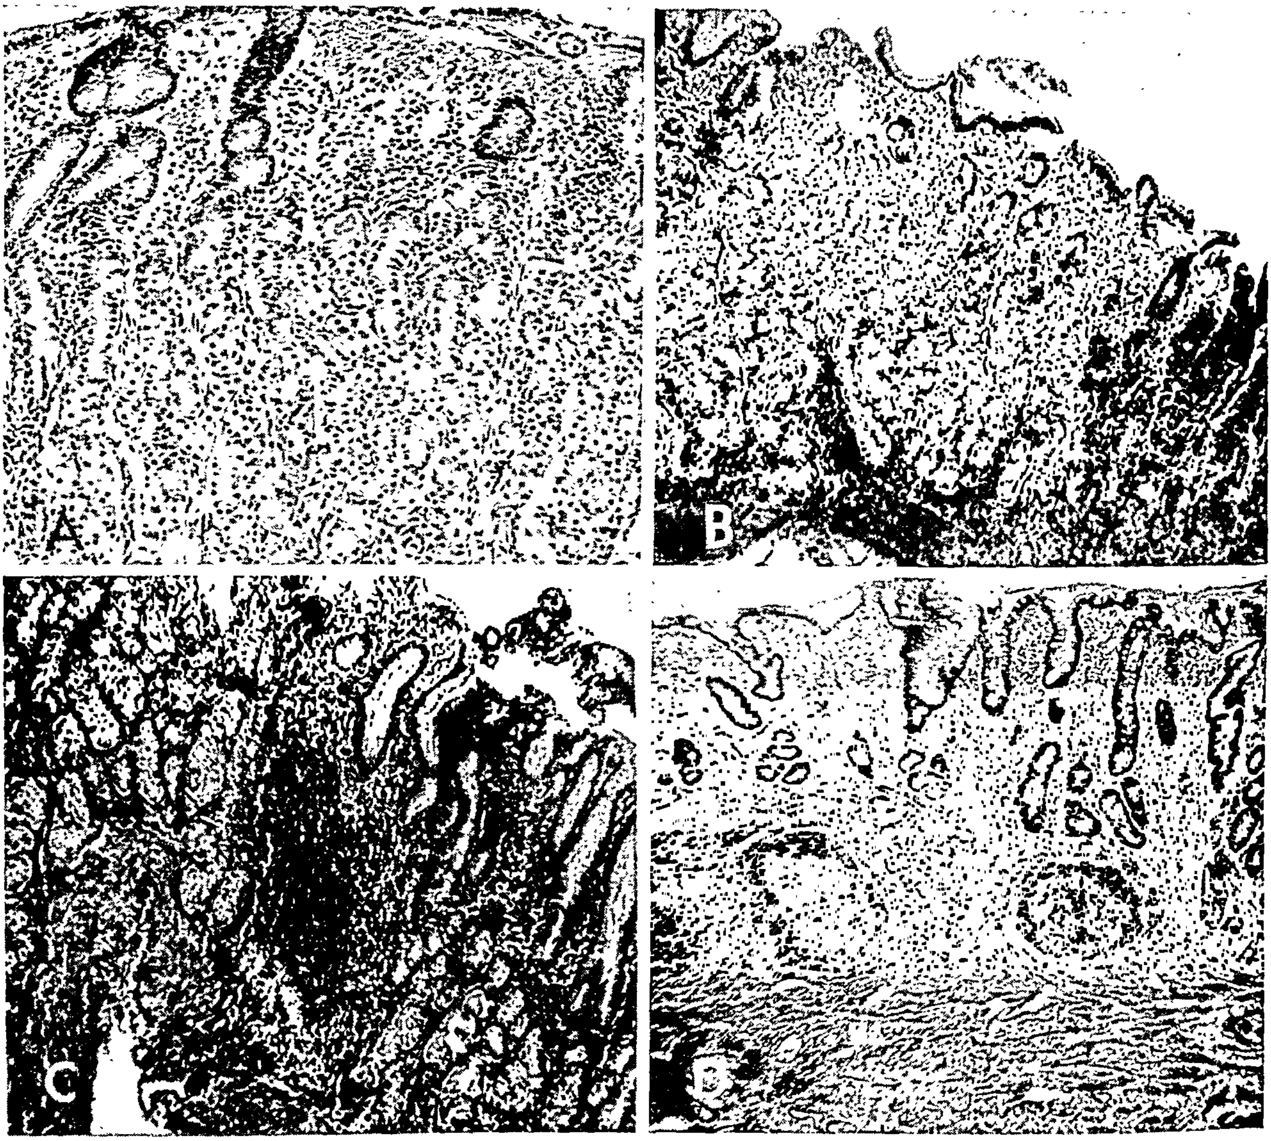
Diagnosis	No. of Patients
Chronic gastritis without associated disease	18
Chronic gastritis associated with	
Gastric atrophy—pernicious anemia	1
Postoperative gastritis	1
Mucosal gastric ulcer	8
Deep chronic gastric ulcer	1
Duodenal ulcer	12
Hodgkin's disease (after definitive surgery)	1
Hodgkin's disease (before definitive surgery)	1
Colon irritability	18
Chronic ulcerative colitis	7
Cancer of colon	1
Portal cirrhosis	2
Hiatal hernia	3
Migraine	4
Chronic relapsing pancreatitis	5
Postoperative cholecystectomy syndrome	1
Chronic cholecystitis	1
Narcotic addiction	1
Glomerulonephritis	1
Myocardial infarction, congestive heart failure, arteriosclerotic heart disease	3
Hypertension	1
Severe deforming arthritis	1
	92

In other experimental studies, application of a topical anesthetic to gastric mucosa blocked histamine-stimulated secretion of gastric acid [7] and prevented contraction of guinea pig ileum.[8]

Clinical Investigation.—A series of 92 patients, 13 to 81 years old, who had chronic gastritis, were examined and treated throughout a two-year study (table 2). Clinical evaluation included repeated history-taking, physical examinations, laboratory studies, and gastrointestinal roentgenograms. To determine whether the lesions were diffuse or patchy, gastric biopsies were routinely taken from three sites—antrum, midstomach, and fundus—in 39 cases, during gastroscopy with the Benedict gastroscope. The material was fixed in 10% formalin, stained with hematoxylin and eosin, and examined by several pathologists in various hospitals in and around Boston. At the same time the gastric aspirate was submitted for Papanicolaou stain and cell block.

Treatment.—Bed rest is essential for all such patients, especially when exhaustion is present. For recurrent episodes of nausea and vomiting, constant gastric suction for 24 to 48 hours affords the speediest relief. After gastric suction the patient is usually pain-free and well prepared for roentgenologic examination of the gallbladder and gastrointestinal tract, laboratory studies, gastroscopy, and surgical exploration if required.

The critical volume of food should be evaluated for each individual and should not be exceeded. Fast days, with bed rest, once or twice a week, help to prevent or diminish the severity of recurrent episodes of pain. Sedatives promote sleep.



Chronic gastritis. *A*, normal gastric mucosa from midstomach proximal to antrum. *B*, mild gastritis: sparse inflammatory infiltrate into interstitial tissue without significant alteration of glands. *C*, moderate gastritis: some disruption of glandular pattern and formation of lymphoid follicle. *D*, severe gastritis: extensive inflammatory infiltrate with lymphoid follicles containing active germinal follicles, intestinalization of glands, and fragmentationof muscularis mucosae.

Medication.—In the majority of the series, doses of 1 tablespoonful of aluminum hydroxide gel three times daily previously had afforded some relief for periods of about two weeks. Since clinical trials of a 0.2% concentration of a compound with local anesthetic action, oxethazaine hydrochloride [N,N-bis-(N-methyl-N-phenyl-t-butylacetamido) beta hydroxyethylamine hydrochloride][7] in aluminum gel, had shown therapeutic efficacy and safety, this combination was used for these patients. One teaspoonful (5 cc.) of the 0.2% solution of oxethazaine hydrochloride in aluminum hydroxide gel (which provides 10 mg. of the topical anesthetic) was administered before meals three times daily. Medication was continued for 6 days to 18 months.

Results.—Ninety-six per cent of the patients obtained complete relief of substernal pain or upper abdominal distress lasting two to six hours after each dose. Four per cent had only partial relief.

The 18 patients who had chronic gastritis with irritability of the colon had not improved on bland diet, anticholinergics, and aluminum hydroxide gel alone. The oxethazaine-aluminum hydroxide preparation permitted earlier use of water, fresh fruits, and fresh vegetables, followed by rapid improvement in bowel function.

The upper abdominal pain experienced by seven patients who had moderately severe chronic ulcerative colitis associated with chronic gastritis was relieved by the medication and the irritability of the gastrocolic reflex was considerably diminished.

The intervals between recurrences were longer and the episodes were milder in severity and more easily controlled. The medication did not mask symptoms of malignant processes in the stomach or colon. No significant side-effects developed.

Comment

Subjective symptoms of an intensity disproportionate to the degree of histological change demonstrated by gastric biopsy were best managed with psychotherapeutic measures. Thus recurrent attacks were reduced and unnecessary operation avoided.

The mild and moderate stages of chronic gastritis appear clinically to be reversible. The severe stage corresponds to the refractory form which fails to show significant improvement under medical management.

The cell block, made from aspirate at the time of gastroscopy, contributed little, although frequently it did contain recognizable gastric mucosa. When ulcer is present in the stomach or duodenum, and the biopsy specimens show normal gastric mucosa or mild or moderate gastritis, the ulcer usually heals under the medical regimen described. If, however, the biopsy specimens exhibit severe chronic gastritis, associated ulcers thus far have been refractory to medical management and appear to be best treated by operation.

Summary

Without biopsy, there is no confirmation of the presence, frequency, type, or extent of gastric pathology. The gastroscopic picture is poorly correlated with the histology of the gastric biopsy. Based on the histological criteria, three well-defined stages of chronic gastritis (mild, moderate, and severe) are recognizable. The severe stage of chronic gastritis appears to be irreversible and corresponds to the clinically refractory type. Mild or moderate chronic gastritis, with or without associated peptic ulcer, usually heals under the medical regimen proposed: gastric suction, physical rest, fast days, smaller meals, and a mucosal anesthetic administered orally in aluminum hydroxide. Peptic ulcer associated with gastritis in the severe form usually does not heal under medical management and is best treated by operation.

CLINICAL NOTES

AGENESIS OF THE BLADDER

James F. Glenn, M.D., Durham, N. C.

Complete absence, or agenesis, of the urinary bladder is an extremely rare developmental anomaly, encountered in only 1 of nearly 600,000 patients seen at Duke Hospital in the past 28 years. Less than 10 instances of agenesis of the bladder are noted in the literature, and these are primarily of academic interest, noted at autopsy.[1] Campbell reports an incidence of seven cases in nearly 20,000 autopsies, most of which showed multiple developmental anomalies.[2] Some recorded cases of agenesis actually represent hypoplasia, contracture, or extreme degrees of exstrophy. This report deals with an instance of agenesis of the urinary bladder with several interesting clinical features.

Report of a Case

A 3½-year-old American Indian girl was admitted to the pediatric service of Duke Hospital in August, 1958, for evaluation of congenital heart disease. Complete cardiologic evaluation, including cardiac catheterization, disclosed a small interventricular septal defect, and it was felt that surgery was not indicated.

At the time of this admission, members of the pediatric staff noted that the patient had continuous urinary dribbling. Urologic consultation was requested. The patient's external genitalia were grossly normal, but careful observation revealed four pin-point openings in the urethrovaginal septum from which urine could be seen issuing.

The patient was discharged and readmitted to the urology service one month later. Information obtained from the parents indicated that no attempt had been made to toilet-train the child, and the parents had noted that the child's diapers remained wet at all times. The patient had 11 siblings, all of whom were said to be without urologic difficulties. With the exception of the cardiac murmur and the continuous leakage of urine the general examination disclosed nothing remarkable. Laboratory data included a normal hemoglobin value and white blood cell count. Blood urea nitrogen level was 36 mg. per 100 cc. Intravenous urograms revealed poor concentration of mediums with bilateral hydronephrosis and hydroureter and reduplication of the upper collecting system on the left.

With the patient under anesthesia a patulous urethral opening could be sounded to 1.5 cm. The vagina was sounded to 4 cm. The four orifices in the urethrovaginal septum were probed, and two of them were found to be fistulas communicating with the other two openings. Two 4 F. ureteral catheters were introduced into the orifices and retrograde pyelograms were taken, revealing bilateral hydroureter and hydronephrosis with reduplication of the left renal pelvis and upper ureter. A 16 F. McCarthy cystoscope was passed into the vagina, which appeared to be grossly normal. A normal cervix was visualized. Cystoscopy revealed the urethra to be a blind pouch about 1.5 cm. in length. There was no evidence of a vesical neck, nor could a trigone be visualized. The mucosa was thin and hypoplastic in appearance. Foley catheters were positioned in the vagina and urethra and were then alternately filled with a radiopaque medium. A urethrogram and a vaginogram were taken. The vaginogram is shown in figure 1. The urethral pouch measured approximately 1.5 by 1.5 cm. when completely distended. Figure 2 shows the artist's concept of the urologic findings.

It was evident that some form of urinary diversion was necessary since no bladder existed and since there was stenosis of the external ureteral orifices with consequent obstruction. Abdominal exploration and ileal loop urinary diversion were performed. After anastomosis of both ureters to an isolated segment of ileum, brought out in the right lower quadrant, approximately 6 cm. of the remaining lower portions of both ureters was excised. The pelvis was carefully inspected and a bicornate uterus noted. The patient's ovarian tubes and ovaries appeared normal. No bladder could be palpated. A normal appendix and a Meckel's diverticulum were removed.

The patient's postoperative course was uneventful. The blood urea nitrogen level became elevated transiently in the postoperative period. Urograms at discharge from hospital showed some resolution of the bilateral hydronephrosis. Adequate urinary collection was achieved through the use of an ileostomy bag. No further urinary leakage through the perineum occurred.

Developmental Anatomy

The development of the genitourinary system is a complex process. The bladder proper arises from entodermal cloaca, while the trigone and ureters arise from mesoderm (mesonephric ducts). The trigone and ureters are hence of Wolffian origin, but the vagina is derived from the Müllerian duct. It has been pointed out that since the vestibule and the ureters have a common origin in the Wolffian body it is not uncommon to find anomalous ureteral openings in the vestibule.[3]

Ectopic ureteral openings are frequently encountered, often associated with supernumerary ureters.[4] Most frequently, ectopia of the ureteral orifice occurs in the urethra or near the external meatus.[1] Extreme cases of ureteral ectopia are recorded,[5] and persistent cloaca has been noted in females.[6]

The most common developmental anomaly of the bladder is exstrophy, and this fortunately occurs in only about 1 in 50,000 births.[7] Agenesis of the urinary bladder is of still less frequent occurrence. Hypoplasia, or dwarf bladder, is also an extreme rarity. Congenital absence of the vagina, on the other hand, is a more frequent anomaly.[8] In dealing with these congenital genitourinary anomalies, emphasis must be placed on a thorough knowledge of the embryology, development, and anatomy of the genitourinary tract.[9]

From the Urologic Division, Department of Surgery, Duke University Medical Center.

Comment

This case of agenesis of the urinary bladder represents a rare urologic anomaly, but it also emphasizes certain aspects of pediatric urology which are of interest to the pediatrician, the urologist, and the family physician alike. It is interesting that this child exhibited multiple congenital anomalies in addition to agenesis of the bladder: a ventricular septal defect was demonstrated and the patient was also found to have double left kidney, a bicornate uterus, and a Meckel's diverticulum. In addition, it should be noted that this child's parents were of a North Carolina American Indian community which is notorious for its high incidence of familial intermarriage.

The most important aspect of this case is the feature of urinary incontinence. It has been previously stated that ectopic ureters are a frequent occurrence, and it is well known that urinary incontinence in children is often of surgical significance.[10] Lanman stated that 50% of children dying from pyelonephritis could be shown to have urologic obstructive lesions which would have been amenable to surgical therapy. Thorough medical evaluation of urinary incontinence is therefore mandatory in all cases.

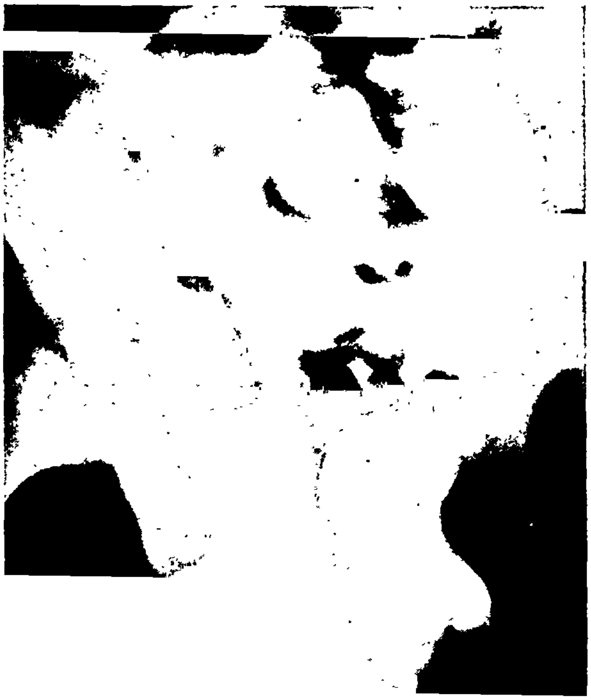

Fig. 1.—Vaginogram of patient. Tip of second catheter remaining in urethra is seen.

The first step in evaluation of urinary incontinence is recognition of the condition. Thorough education of parents is required if they are to observe the urologic habits of their children. Many infants are never observed in the act of voiding, and a surprising number of mothers are unaware of the intervals between diaper changes. A diaper which is continuously wet despite frequent changes is naturally one of the first signs of urinary incontinence.

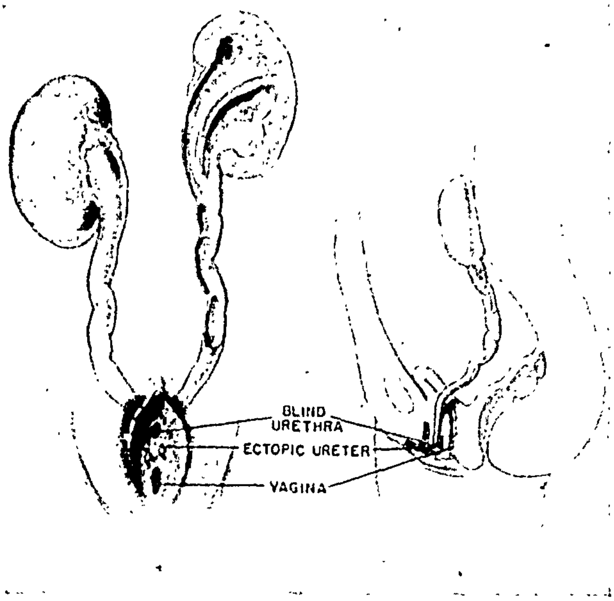

Fig. 2.—Composite drawing showing blind urethra, ectopic *orifices, bilateral hydroureteronephrosis,* and left double kidney.

Urologic evaluation should not be delayed. Ectopic ureteral orifices are usually surrounded by tissue producing obstruction and leading to prolonged urinary infection with pyelonephritis and renal damage. Other cases of urinary incontinence are equally serious, including bladder neck obstruction due to contracted vesical orifice or congenital urethral valves with resultant overflow incontinence. Congenital urinary fistulas with or without communication with the gastrointestinal tract also demand early surgical correction.

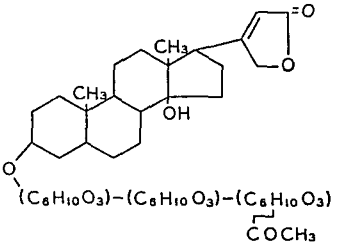
COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based upon available evidence and do not in any case imply endorsement by the Council.

H. D. Kautz, M.D., *Secretary.*

Acetyldigitoxin (Acylanid).—The alpha acetyl ester of digitoxin.—The structural formula of acetyldigitoxin may be represented as follows:



Actions and Uses.—Acetyldigitoxin, introduced in 1954, is a crystalline cardiac glycoside which is derived from lanatoside-A (a naturally occurring glycoside of Digitalis lanata) by chemically controlled, enzymatic removal of a glucose molecule. Clinically, the drug produces the therapeutic and toxic effects of digitalis and related principles. Acetyldigitoxin is characterized by a relatively rapid onset and a short duration of action as compared with digitoxin. Typical digitalis effects become discernible within two to four hours after oral administration. Because the drug is dissipated more rapidly than digitoxin, its effect is more quickly reversible; signs of intoxication disappear within one to three days after discontinuing treatment. Approximately 66% of an orally administered dose is absorbed from the gastrointestinal tract.

Acetyldigitoxin is used in the same manner as other cardiac glycosides for the treatment of congestive heart failure and/or auricular fibrillation and paroxysmal tachycardia. The drug has a high rate of fixation to serum albumin and is, therefore, well suited for maintenance treatment in chronic heart failure. Its bradycardic effect is pronounced in patients with auricular fibrillation who have a rapid heart rate. (See the general statement on digitalis and related principles in New and Nonofficial Drugs.)

Although acetyldigitoxin has shown a slightly more favorable therapeutic ratio in some studies, its toxic potentialities are the same as with other digitalis preparations. As with all other cardiac glycosides, constant supervision is imperative to avoid the adverse effects of overdigitalization. Gastrointestinal symptoms, which may be expected in approximately 20% of patients despite the most careful adjustment of dosage, are indicative of excessive dosage. Such effects usually precede cardiac arrhythmias and are readily reversible upon reduction in dosage or discontinuance of medication.

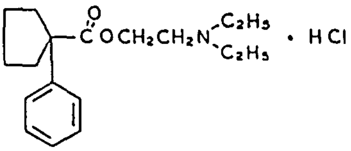
Dosage.—Acetyldigitoxin is administered orally for digitalization and maintenance. Since the drug is a pure glycoside, which is chemically well defined and stable, it is standardized gravimetrically rather than by biological assay. Dosage must be carefully adjusted according to the response of the individual patient and the appearance of toxic manifestations.

For rapid digitalization, 1.6 to 2.0 mg., with an average of 1.8 mg., is given within 24 hours, either as a single dose or in three or four divided doses. Some investigators have employed as much as 3.0 mg. in one day for initial digitalization, but this dose appears to be excessive from the standpoint of toxicity. For slower digitalization, daily amounts ranging from 0.6 to 1.4 mg., with an average of 1.0 mg., may be given for two to six days. Alternatively, the drug may be given in doses of 0.2 mg. three or four times daily until the therapeutic effect is achieved. The average maintenance dose of acetyldigitoxin is 0.15 mg. per day, with a range of 0.1 to 0.2 mg.

Preparations: tablets 0.1 mg. and 0.2 mg.

Sandoz Pharmaceuticals, Division of Sandoz, Inc., cooperated by furnishing scientific data to aid in the evaluation of acetyldigitoxin.

Caramiphen Hydrochloride (Panparnit).—2-Diethylaminoethyl 1-phenylcyclopentanecarboxylate hydrochloride.—The structural formula of caramiphen hydrochloride may be represented as follows:



Actions and Uses.—Caramiphen hydrochloride, introduced in 1949, is a synthetic antispasmodic agent which is used in the medical management of paralysis agitans (Parkinson's disease). It may be classified pharmacologically as an atropine-like drug. However, it has much weaker mydriatic and antisecretory effects than do the belladonna alkaloids while, at the same time, exerting a potent spasmolytic effect on smooth muscle. Caramiphen also relieves spasticity of voluntary muscle, an action believed due to peripheral cholinergic blockade plus central inhibition on cerebral motor centers.

Caramiphen is generally considered to be better suited for so-called postencephalitic Parkinsonism than for the "arteriosclerotic" or "idiopathic" types of the disease. The drug apparently has little effect on tremor but, in favorable cases, may afford some relief from rigidity. This relief is by no means complete; therapy is usually considered beneficial if muscle spasm is relieved by about 25%. As with other anti-Parkinsonian agents, there is no reliable criterion on which to predict responsiveness to caramiphen. In general, however, patients who respond well to the belladonna group of drugs will also show a favorable response to caramiphen. Although caramiphen appears to serve a useful purpose for the symptomatic treatment of some patients with paralysis agitans, it should be borne in mind that the long-term management of this disease with any therapeutic agent is unsatisfactory.

Giddiness and weakness occur frequently during the course of therapy with caramiphen. Other less frequent side-effects are chiefly atropine-like and include dryness of the mouth, blurring of vision, dizziness, faintness, and hypotension. Owing to its anticholinergic classification, caramiphen should be used cautiously, if at all, in patients with glaucoma, prostatic hypertrophy, urinary retention, or marked vegetative nervous system dysfunction.

Dosage.—Caramiphen hydrochloride is administered orally. Dosage must be highly individualized according to therapeutic response and appearance of side-effects. Initial dosage should be low, and the increase gradual. Changes from other anti-Parkinsonian medication should also be gradual, without abrupt stoppage of the previously used drug. Individual doses of 12.5 mg. may be given five times on the first day, with daily increments of about 50 mg. in the total daily dose until disagreeable side-effects begin to outweigh the beneficial effects. Maintenance doses generally range from 90 to 600 mg. a day, given in divided doses at intervals of two to three hours, throughout the day.

Preparations: tablets 12.5 mg. and 50 mg.

Geigy Pharmaceuticals, Division of Geigy Chemical Corporation, cooperated by furnishing scientific data to aid in the evaluation of caramiphen hydrochloride.

Safflower Oil (Saff).—An oily liquid extracted from the seeds of the safflower, Carthamus tinctorius. Safflower oil contains 74.5% linoleic acid and 6.6% saturated fatty acids.

Actions and Uses.—Safflower oil is a natural substance rich in linoleic acid, an essential unsaturated fatty acid. When given in sufficient quantities to subjects with hypercholesteremia, certain unsaturated fatty acids (including those in corn oil and cottonseed oil) have been reported to lower serum cholesterol levels. This effect is variable and is not readily discernible in subjects with normal or near normal cholesterol levels. Safflower oil does not lower serum cholesterol levels to any appreciable extent unless it is substituted for saturated fatty acids already in the diet. For maximal lowering effects, it is necessary to achieve a certain ratio of food fats; this ratio should be approximately one part saturated fatty acid to three parts unsaturated fatty acids. This means that, for an appreciable effect, large amounts of unsaturated fatty acids such as those in safflower oil must be given while the intake of ordinary dietary fat is drastically reduced.

Safflower oil was introduced in 1957 and is proposed for clinical use in patients with hypercholesteremia with a family history of heart disease, in patients who have suffered myocardial infarction, and in those displaying evidence of coronary insufficiency. The rationale for such use stems from the statistical relationship that is commonly supposed to exist between elevated blood cholesterol levels and the frequency of atherosclerosis and its clinical complications. The fact that there is a significant statistical relationship between two variables does not prove that one causes the other. Nevertheless, it seems reasonable to postulate that sustained reduction in blood cholesterol levels, for which safflower oil is proposed, may be desirable. It remains to be shown, however, that safflower oil or any other cholesterol level-lowering agent has any effect, good or bad, in terms of the over-all physical status of the patient. Its clinical use must therefore be considered experimental.

In contemplating the use of safflower oil, it should be borne in mind that the proposed daily dose provides about 450 calories. If taken without a corresponding reduction in regular dietary calorie intake, weight gain may be expected. This is undesirable, since obesity in itself is commonly associated with elevated blood cholesterol levels. In fact, hypercholesteremia may often be improved simply by a program of weight reduction. For these reasons, special care should be given to the administration of safflower oil to obese patients.

Except for a slight tendency to produce diarrhea, safflower oil has been notably free of side-effects. Like other fats, it is a cholecystagogue and should be used cautiously in patients suffering from gallbladder disease.

Dosage.—Safflower oil is administered orally. The proposed daily dose is approximately 75 cc. of a 65% emulsion given in divided doses. To have any effect, therapy with safflower oil must be accompanied by a simultaneous reduction in the intake of animal fats and hydrogenated vegetable oils.

Preparations: emulsion (oral) 65%.

Abbott Laboratories cooperated by furnishing scientific data to aid in the evaluation of safflower oil.

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The Council has authorized publication of the following report.

PHILIP L. WHITE, SC.D., *Secretary.*

AWARD OF RESEARCH FELLOWSHIPS IN CLINICAL NUTRITION

Ten fellowships for research in clinical nutrition have been awarded by the Nutrition Foundation, Inc., and the Council on Foods and Nutrition. They have been given in honor of Dr. Virgil P. Syndenstricker, recipient of the 1958 Joseph Goldberger award in clinical nutrition. A fellowship is granted to a medical student to permit him to carry on research in some phase of clinical nutrition during the nonacademic portion of the school year. Each grant consists of $600. Application is made by a senior investigator, and the fellowship is administered by him. The Council was impressed with the interest shown in these fellowships and had a difficult time selecting 10 from the many meritorious applications submitted.

This fellowship program is a part of the joint effort of the Nutrition Foundation, Inc., and the Council on Foods and Nutrition to stimulate staff members and students of schools of medicine to take a more active interest in the science of nutrition as an integral part of medical practice.

The 1959 fellowships have been awarded for the following research:

1. Niacin and niacin-containing cofactors in hepatic lymph. Senior investigator, L. S. Dietrich, Ph.D., department of biochemistry, University of Miami.
2. The possible biosynthesis of vitamins A and D in fish. Senior investigator, James H. Jones, Ph.D., department of biochemistry, University of Pennsylvania.
3. The effects of iron stores and growth on iron absorption. Senior investigator, Thomas C. Chalmers, M.D., department of medicine, Harvard University.
4. Vitamin supplementation and the excretion of urinary oxalate. Senior investigator, Hans H. Zinsser, M.D., department of urology, Columbia University College of Physicians and Surgeons.
5. Cholesterol and carbohydrate metabolism. Senior investigator, W. H. Sebrell Jr., M.D.; student, Kenneth J. Berkes Jr., Institute of Nutrition Sciences, Columbia University School of Public Health and Administrative Medicine.
6. Studies on the rate of hydrolysis (in vivo and in vitro) of vitamin A esters. Senior investigator, Edward G. High, Ph.D., biochemistry department, Meharry Medical College.
7. The determination of body density of infants and children and the effect of diet on body composition. Senior investigator, Samuel J. Fomon, M.D., department of pediatrics, State University of Iowa.
8. An enzymatic and metabolic study of specific amino acids and the effect of certain nutritional conditions. Senior investigator, Alton Meister, M.D., department of biochemistry, Tufts University.
9. Protein and amino acid requirements of rats following experimental injury. Senior investigator, Otto W. Neuhaus, Ph.D., department of physiological chemistry, Wayne State University.
10. The relationship of lipemia clearing to coronary artery disease. Senior investigator, John F. Mueller, M.D.; student, Robert Poe, department of internal medicine, University of Cincinnati.

Credit at the Hospital

The use of credit cards has become so widespread that at least one confident card holder tried to use his recently to pay a traffic fine. The fact that he failed indicates only that traffic courts are included in the diminishing minority that still insist on hard cash payment. Even hospitals, it appears, are taking the cue.

In Savannah, Ga., the 55-bed Telfair Hospital has instituted a credit card system of its own. Theirs is actually an improvement on the standard system since it not only establishes an immediate credit standing, but also relieves the patient or his family of lengthy recital of social history, formerly required for admission.

Here is how it works:

Every person with a previous acceptable credit experience at the hospital is mailed a "Master Social Information Sheet." When the information is returned, a credit card is issued for each member of his family. At the time of hospitalization, the patient need only present this card to the admitting clerk.

Upon discharge, he is free to leave the hospital without business office clearance. A bill for all charges is sent at the end of the month.

Card requests from persons without past credit experience at the hospital follow the same procedure except that a full credit statement is obtained and the application is checked through the local credit bureau.

Telfair Hospital believes the new plan not only greatly facilitates admissions and discharges but builds good will at the same time.

Left, children risk death by suffocation when they toy with plastic material. *Right,* Dr. Paul B. Jarrett, who recognized widespread hazard after four children died in Phoenix.

How One Physician Warned a Nation

Medicine and the Press—A Case of Joint Effort to Sound an Alarm

Milton Golin

The stories his colleagues were telling to Dr. Paul B. Jarrett of Phoenix carried an ominously familiar ring. Four children had died in recent weeks—suffocation while playing. What were they playing with? The other physicians told him: Plastic garment bags—why do you ask?

Because he did ask, thousands of physicians and patients across the land now are alerted to another of the many dangers which threaten the lives of children in our growingly complex society. This is what happened after Dr. Jarrett became curious and got his answers:

He determined on further inquiry that a number of laundry and dry cleaning establishments in the Phoenix area—like places elsewhere in the United States—in recent months had been substituting thin plastic bags for the paper sacks previously used for finished garments. He also learned that some parents were tossing the plastic to their children as "toys" after removing the cleaned clothing. Often the happy youngster, quite naturally, would place the bag over his head. Dr. Jarrett is reasonably certain that is what happened to the four children who suffocated in his city. Listen to his version of what probably ensued:

"An electrostatic charge may have been generated by friction from handling. The youngster, in peering through this material, is apt to have it literally grab him through electrical attraction to his face. If this happens only the prompt intervention of an adult will prevent tragedy. This dangerous material won't tear when a child fights it. Dizziness, inability to think, spasms of muscles occur with more and more rapid breathing. Vomiting with inhalation of undigested food puts a finish to this terrible tragedy."

Time for Alert

Now came the time for alert. Dr. Jarrett, conferring with fellow officials of the Maricopa County Medical Society (he is chairman of the safety committee and is credited with bringing about installation of seat belts in all state highway patrol cars and in many private autos in Arizona), helped draft a warning bulletin. He sent a copy to the *Arizona*

Republic, a newspaper whose editorial staff immediately recognized a public service duty inherent in the news itself. A news photographer posed a picture of a boy hooded by a plastic bag, to further illustrate the hazard.

At the same time, the county medical society early this year notified Bernard J. Conley, Ph.D., secretary of the A. M. A. Committee on Toxicology, which for years has been sounding the alarm of child-poisoning dangers lurking in many innocent-appearing household chemicals (see box and also Medicine at Work, THE JOURNAL, Jan. 12, 1957). Dr. Conley, in turn, saw an urgent need to broadcast the notice.

Citing the situation in Phoenix and quoting from the newspaper report, he sent letters to Metropolitan health departments, poison control centers, and other interested groups and individuals in scattered parts of the country. The reaction was immediate. In New York City, the assistant health commissioner, Dr. Harold Jacobziner, helped prepare a technical notice entitled, "Infants Dying from Suffocation by Plastic Material," and it was distributed to all poison control centers, maternal and child staffs, and superintendents of hospitals in that metropolitan area. Chicago's health commissioner, Dr. Herman N. Bundesen, last month took similar action. And in other communities, large and small, the danger was made known, always with the cooperation of local newspapers. At last report, the National Safety Council was preparing to publish an alert in its *Home Safety Review*.

Lives Saved

There is no way of determining how many young lives will be saved because of one physician alerting many—and because of newsmen then carrying the word to millions. That young lives were and will be saved cannot be doubted, however—just as death is being averted in similarly immeasurable medicine-press efforts involving abandoned ice boxes, imported highball stirrers containing toxic beans, and poison-laden Christmas ornaments. In those efforts, too, starring public service roles have been played by individual physicians and individual newsmen, by medical societies at all levels, and by newspapers in all ranges of circulation.

Meanwhile, Dr. Jarrett, the Phoenix surgeon who helped sound the early alarm, feels it cannot be repeated too often. He says: "Such a horrible combination as a child playing with a venomous reptile would not result in death as quickly as suffocation by the plastic film which clings . . . with diabolical tenacity. These deaths are the result of carelessness. They could have been prevented. Through knowledge they will be prevented in the future."

Chairman of the A. M. A. Committee on Toxicology is Dr. Torald H. Sollmann of Cleveland Heights, Ohio. Other members are Drs. Harvey B. Haag of Richmond, Va.; Irvin Kerlan of Washington, D. C.; Jay M. Arena of Durham, N. C.; Arnold J. Lehman of Washington, D. C.; Edward Press of New York City; Mr. Justus C. Ward of Washington, D. C.; and Mr. Jerome Trichter of New York City. Bernard E. Conley, Ph.D., of Chicago, is Staff Secretary.

Stuff That Poisons

A recent compilation of newspaper clippings which cover the period of 1955 through 1958 shows that 707 persons died in the United States as the result of accidental poisoning. The A. M. A. Committee on Toxicology, which collects such news items, reports that poisoning from internal medications dominates the pattern of nonfatal injury. Next in frequency are cases due to insecticides and rodenticides—followed by household chemical agents, industrial and other solvents, and miscellaneous products such as cosmetics. Recently, the Committee secretary met with representatives of the National Safety Council and the National Association of Poison Control Centers to consider a public educational campaign on the prevention of accidental poisoning.

School Sports May Be Healthful, But They Are Not Health Education

The academic tendency to make health education a stepchild in the curriculum has become commonplace in some public schools.

It was with this in mind that the Joint Committee on Health Problems in Education recently called for a re-emphasis on health teaching. The Joint Committee—which unites the American Medical Association, and the National Education Association in common cause—did not ignore physical education; in fact another of the group's resolutions called attention to opportunities in this field. But members did take pains to point out that health courses deserve consideration on their own.

This resolution on health teaching, approved at the Joint Committee's meeting in Chicago last month, calls on educators to employ teachers qualified in this field, and to allow them adequate class time to develop a comprehensive program. Adequate class time is defined as one period a day for one year in both junior and senior high schools.

Other Joint Committee resolutions call for increased physician interest in the health and health education problems of schools, special attention to health challenges generated by the use of school buses, and control of the hazards inherent in the use of carbon tetrachloride in science classes.

Much of the Joint Committee's three-day session was spent in editing its publications, a common group activity. Less common was its appointment of a subcommittee to plan a 1961 ceremony to celebrate the Joint Committee's own birthday—its 50th.

When 64 Health Groups Foster The Well-Being of Workers

Medical societies, through meeting periodically in factories, can promote occupational medicine.

Consumers foot the bill when a company neglects employee health.

We are entering the atomic age without having solved all the health problems of the machine age.

Farming is more hazardous than any other single occupation.

Those sample points were brought out in Chicago last month for more than 500 representatives of government, labor, management, and medicine who attended a three-day forum sponsored by the National Health Council. The conference on "The Health of People Who Work," was under the chairmanship of Dr. James H. Sterner, medical director of the Eastman Kodak Company and a member of the A. M. A. Council on Industrial Health. The A. M. A. is one of 64 sponsoring agencies of the National Health Council. Following are selected quotes from participants in formal presentations, panel discussions and informal news conferences:

The medical society should foster education in the general area of occupational health during the undergraduate medical school years, since every physician will be called on to administer to the industrial worker at one time or another.

—Dr. Kieffer Davis, medical director,
Phillips Petroleum Company

The doctor needs from management adequate assistance and support to permit him to spend much more time in evaluating and improving the work environment than in sewing up fingers and dispensing pills.

—Dwight J. Thompson, executive vice-
president, Champion Paper and Fibre
Company

I would estimate that 90% of the health problems in industry are not occupationally-oriented, and that half of these are either emotional or have emotional overtones.

—Dr. David Goldstein, medical director,
New York Times

An industrial worker does not pick up his heart or his lungs or his body at the factory gate when he checks in. Nor does he leave them there when he checks out. Industrial health is tied up with home health.

—A. J. Hayes, president, International
Association of Machinists

Why is freedom of choice of physician important? Because it aligns the inherent drive of the doctor to succeed in his profession with the best interests of the patient and therefore the public. Common sense tells us that the physician's dedication to high professional standards will be reinforced by enlightened self-interest.

—E. J. Faulkner, president, Woodman
Accident and Life Company

Even with elaborate and early preparation, many who reach 65 become the lost generation when they are forced to retire. It is important to retire to something. To make a messenger boy out of a college president is to promote mental and physical deterioration.

—Dr. Frederick C. Swartz, chairman,
A. M. A. Committee on Aging

The vast number of organizations for health need to be seen not only in relation to their individual purposes, needs and values, but also as they relate to other health organizations and to the cultural, economic, political and scientific environment.

—Ruth B. Freeman, Ed. D., incoming
president, National Health Council

Dr. Freeman announced that next year's Forum will deal with "Health of Older People," under the chairmanship of Dr. Edward Bortz, former A. M. A. president and now a consultant to the Committee on Aging. That topic is as far-reaching, she noted, as this year's, which President Eisenhower described as follows in a telegram read at the opening Forum session on March 17:

"'The Health of the People Who Work' represents a challenge directly related to technologic progress in preventive health measures. It involves the well-being and productivity of almost 70 million workers. This is a challenge which can be met only by the combined efforts of management and labor, the health professions, government, private and voluntary health agencies, and civic and community groups."

Exams for Executives

Opinions that executives are more subject to unusual stresses and strains because of the positions they hold were critically evaluated at the most recent meeting of the A. M. A. Committee on Medical Care for Industrial Workers.

Members suggested that a 1957 A. M. A. policy statement on health examinations was just as applicable to executives as to other employees. They also felt that the examinations should be done locally to encourage continuity of care and follow-up. Committee members, citing observation and study, expressed the opinion that executives are not subject to any more stress and strain than other employees, but suggested that further exploration of such examinations, under adequate statistical control, might provide more reliable conclusions.

The Committee on Medical Care for Industrial Workers operates jointly under two Councils. Its report was discussed by the Council on Industrial Health last month and will be reviewed by the Council on Medical Service on May 2.

Industrial Health Posers

Immunization and Screening—Who, When, and for What?

What an occupational health program ought to do and how it ought to do it was suggested by the A. M. A. House of Delegates in a policy statement issued in 1957 (The Journal, July 6, 1957). But like all general documents, it dwelt on broad principles rather than specific judgments.

In an effort to shed light on some special problem areas that have become apparent, members of the A. M. A. Council on Industrial Health recently discussed proposed guide lines for industrial immunization programs and multiphasic screening examinations. The Council met in Cincinnati on Feb. 14 and 15 prior to the 19th annual Congress on Industrial Health.

In discussing a proposed guide for immunization, the Council pondered three major questions:

—Should an employer provide the protection for employees who, by reason of their occupation or job assignment, may be exposed to significant hazards against which immunization procedures are available?

—Should an employer provide these procedures in the face of an impending epidemic which threatens to disable so large a proportion of his employees as to interfere materially with operations, and against which immunization would not or could not be applied by community health resources in a short enough period of time to afford optimum protection?

—May an employer participate in community-wide immunization programs at the request of, and in cooperation with a local medical society and community health agencies?

On the matter of multiphasic screening examinations (relating to a battery of tests), especially those in which mobile laboratory units are used, committee members expressed the opinion that such screening, in selected instances, might be worthy of future trial if carefully conducted and confined to a relatively few, simple tests—such as urinalysis, hemoglobin level determination, differential blood cell count, and chest x-ray, according to the needs of the particular situation.

They felt that if such screening is related to the occupational environment, it should be considered to come within the scope, objectives, and functions of the occupational health programs, as set forth in the official A. M. A. statement. These same committee members also expressed the opinion that multiphasic screening should include provision for a follow-up program, that the tests should be performed by qualified personnel, and that the interpretation should be made by the individual's personal physician.

Members and staff of A. M. A. Council on Industrial Health meet in Cincinnati.

Rehabilitation Directory—New Instrument for the Physician

A patient recovering from severe illness or disability often needs more than continuing medical aid to resume his place in society. But how can physicians guide him to other agencies to meet his need for social service, vocational counseling, or job placement?

Feeling that this is an area in which state and county medical societies can be of help to their members, the A. M. A. Committee on Rehabilitation, meeting last month in New Orleans, approved a booklet that tells "how to do it." Called "Medicine's Back to Work Plan," the pamphlet is based on recommendations, made last December by the House of Delegates, which urges state associations to form committees on rehabilitation.

The purpose of these committees would be to review state-wide rehabilitation programs and to establish liaison with other groups interested in the problems of the disabled and handicapped. The House also recommended that state associations urge county societies to survey the rehabilitation facilities available in their areas.

Such surveys could be used, the booklet states, to develop informative rehabilitation services directories. Designed for the use of physicians and others interested in the challenges of rehabilitation, such directories should list hospitals, nursing homes, nursing agencies, rehabilitation centers, training schools, sheltered workshops, and social and family service agencies. A sample survey form and suggestions for the preparation of a local directory are included in the booklet, which states:

"More than two million disabled persons in the U. S. today could be restored to useful jobs—if shown proper guidance and care, taking into consideration the abilities they still have, and their physical limitations."

Keeping Them Healthy Down on the Farm

Hampered, but not defeated, by a late winter blizzard that boomed across the plains, nearly 600 rural residents from several Midwest states gathered in Wichita, Kan., last month for the 14th National Conference sponsored by the A. M. A. Council on Rural Health. They joined physicians, nurses, teachers, editors, extension workers, and dentists in discussions of such challenges as mental health, the cost of medical care, animal diseases that affect humans, and health education.

"How you feel about other people is one aspect of mental health," said Dr. Alonzo Peeke, a general practitioner from Volga, S. D. "It's also how you get along with yourself, and how you are able to meet the demands of life. It's far more than just the absence of mental illness."

Dr. Prescott W. Thompson cautioned his audience that facilities for the care of mental patients must be "hospitals" in every sense of the word. Dr. Thompson, who is director of outpatient service for the Menninger Clinic, said: "To the lay public, the mental hospital is the most visible evidence of what psychiatry is and what it has to offer. These hospitals must shed any resemblance to the old asylums with their gloomy exteriors, and their hopeless interiors."

Dr. Thompson believes that such rejuvenation is important for two reasons: The patient and his family must view the mental hospital as a treatment center—a place in which to get well; and a good mental hospital is the best means by which to recruit medical students and others into psychiatry and its related disciplines.

In discussing the cost of modern medical care, Dr. Conrad Barnes of Seneca, Kan., said: "Increases are mostly in the fields of drugs and hospitalization, and are certainly justifiable in the light of modern medical care." He noted that while modern drugs and hospital techniques may be expensive when compared with those of "grandfather's day," they actually constitute an economy in getting patients well faster and better. "Consider the reduction in communication time between major cities from days to seconds," Dr. Barnes said. "It was done only at a tremendous cost, but who would say the new service was not worth it; who would want to go back to the 'good old days'?"

Control of disease in animals, Dr. Martin P. Hines told the conferees, is an area in which enlightened rural groups cooperating with veterinarians, physicians, and public health workers have made dramatic progress. Dr. Hines is the chief of the Veterinary Public Health section of the North Carolina State Board of Health and a member of the Council's advisory committee. He noted that effective campaigns have been waged against Texas fever, bovine tuberculosis, and brucellosis. He warned, however, that other diseases have appeared to take their place. Leptospirosis is one; Q fever is another.

Despite the apparent success of modern agricultural methods, Dr. Hines pointed out that 10% of all farm animals died last year from diseases or parasites. "Mastitis alone," he said, "causes an annual 5% loss in milk production."

In addition, many animal diseases are secondarily transmissible to man. Such zoonoses now number more than one hundred. He said: "Among the difficulties contributing to the control of animal diseases are: the poor understanding of the ecology of man, animals, and birds; faulty diagnosis and reporting systems, and the fact that rural dwellers often feel they must live with many of these diseases."

Calling for a "temporary partnership between

One Woman's Opinion

"Take the tractor, boys, and pull old Doc Schneider out of that mudhole." The fact that her physician-husband was fresh out of internship made the terminology incongruous, but to Mrs. Kenneth Schneider of Brown County, Indiana, it also meant that she and her husband had been accepted by the rural community in which they had chosen to settle.

Some of the trials of their rural practice were told by Mrs. Schneider to those who attended last month's A. M. A. Conference on Rural Health, but the diminutive housewife and former nurse left her audience with no doubts about the country being a good place to live.

Mrs. Schneider told how she and her husband, both city reared, took the first plunge into practice in a town of 526 people in partnership with another married physician. Their first office (where she served as nurse) was in a makeshift space above an appliance store, and both couples lived in the same 50-year-old building. Today, they have a modern clinic, and Dr. and Mrs. Schneider live in a home built on an acre of rolling, wooded ground four blocks away. She says:

"Kenny does all those things many think a family doctor no longer does—performing minor surgery, setting fractures, prescribing medicine, delivering babies, making home calls, and acting as family confessor. The partnership assures us that patients will always be taken care of, and he still has time to spend with his family."

Romance sometimes became enmeshed with medicine in those first days. Mrs. Schneider recalled one time when she had gone with her husband on a night call, and he put his arm around her as they rode home in the moonlight. "Honey," he said as she waited expectantly, "did you notice that patient's hyperactive reflexes?"

Audience as well as program speakers air their views on multiple challenges of rural health at A. M. A.-sponsored National Conference in Wichita.

patient and physician during treatment," Dr. F. S. Crockett, chairman of the A. M. A. Council on Rural Health, said such an arrangement was vital to health. "The doctor examines, diagnoses, and prescribes," he said, "but it is the patient who must follow directions, and do what he can to get well and stay well."

Health Versus Patronage In Youngstown, Ohio

It took more than 14 years, but the Mahoning County Medical Society—with the help of dentists, druggists, veterinarians, and members of other health groups—finally has won its battle to get a full-time physician health commissioner for the 170,000 residents of Youngstown, Ohio. The story is another example of physicians working with others to solve a community problem (see Medicine At Work, THE JOURNAL, March 16, 1957).

The concerted effort that succeeded in amending the city's charter to call for a professional health officer began in early 1957 when the society's new president, Dr. Stephen Ondash, persuaded the group to take it on as a project. Even this was no simple matter since the society had tried repeatedly to persuade the city council to put such an amendment on the ballot for a referendum, and for 14 years the efforts had failed. The chief reason

Workshops Help Kansans Solve Their Own Health Problems

Participants at one session of the recent A. M. A. National Conference on Rural Health became citizens of an imaginary town called America. The purpose of the transformation was to show how community workshops are being used to help solve the health problems of many Kansas communities.

Such workshops are sponsored by the state medical association and its county societies and are guided by Dr. V. E. Wilson, assistant dean of the University of Kansas School of Medicine, and Mr. Oliver E. Ebel, executive secretary of the Kansas Medical Society. At the request of any Kansas community, they recruit a team of resource people—physicians, public health workers, educators, clergymen, engineers, and sociologists—to staff a meeting of the town's residents.

No attempt is made by the visitors to either identify the community's major health problems nor to volunteer possible remedies. Instead, the moderator asks individual residents to state their community's problems. In explaining the method to his Conference audience, Mr. Ebel said that such an approach usually elicits many difficulties the town is experiencing, and that the audience itself soon decides on those that are uppermost.

Having succeeded in identifying the problems, the moderator then asks members of the audience to suggest possible solutions. "Usually," Mr. Ebel told his listeners, "once the meeting has reached this stage, all it needs is guidance." Those who have attended as resource persons offer information only when asked and confine their remarks to relating the experiences of other communities with similar challenges.

Even those attending the Rural Health Conference, in their capacities as residents of the fictional town of America, found a good many things to be concerned about. The afternoon session generated considerable discussion about the length of time children must spend on school buses, the lack of physical examination requirements for school children, the travel required to see a dentist, and facilities for the aged.

In actual practice, Mr. Ebel said, these meetings may vary in length from one to three days and occasionally take some surprising turns. One gathering became so interested in the construction of hospital facilities that an expert in this field, missing from the resource panel on the first day, was alerted and arrived by plane in time for the second day's session. In another, enthusiastic citizens enticed members of the town's council into the hall for a full scale airing of a community sore point: garbage disposal.

was that the new position required a civil service rating, and politicians of both parties preferred to see it remain an appointive patronage plum.

A Public Health Committee headed by Dr. John J. McDonough first approached the city council with a request that the charter change be submitted to the voters. Expecting a refusal, it also went ahead with preparations for a widespread petitioning. The councilmen did refuse, and so the committee mounted a massive two-fold campaign—first to acquire the thousands of signatures necessary to force a referendum, and second to educate the citizens of Youngstown to the desirability of the charter revision.

Petitions were sent to every physician, dentist, chiropodist, and druggist in the city. Next went weekly letters reminding them of the importance of the effort. Their secretaries were spurred in their efforts to collect signatures by the offer of three cash prizes for the most successful, and members of the woman's auxiliary checked on the progress of their husband's petitions. When the time came to file, the committee found its petitions had 13,000 signatures, more than the required percentage to get the question on the ballot.

Then began the second stage of the campaign—to convince Youngstowners that they ought to vote for the charter amendment. With the aid of an advertising agency, a brochure was prepared explaining the value of a qualified health commissioner. A copy was mailed to every city residence, and other copies were displayed by doctors, dentists, pharmacists, veterinarians, and hotel keepers. Advertisements were placed in newspapers, and on radio and television. And above all, speeches were made. "I spoke publicly on the subject more than 30 times myself," said Dr. McDonough.

Voters saw the value of the amendment and passed it by a substantial majority last November.

For a time thereafter, it appeared that getting the charter revised might have been less of a task than finding a physician to fill the position it had created. The supply of doctors interested in public health did not begin to meet the demand.

Then, entirely unsolicited, Dr. Leonard A. Blum appeared. After 24 years of private practice in Niles, Ohio, he left to obtain a master's degree in public health. Having done so, he sought to return to his birthplace—Youngstown. On invitation, he met with the new board of health, and was hired.

Youngstown now has its first full-time, qualified health commissioner.

Shoestrings, Lions, and Doctors

Combining Salesmanship with Public Service in Quest for Better Health

Thanks to a handful of matchbooks and three scraggly shoelaces, medical service is available today in the little town of Ariton, Alabama (population 750). There's more to it, of course—such as people, perseverance, and pride in community. Also involved is an all but fantastic new twist on the old story about selling refrigerators to Eskimos.

The Ariton story began a half dozen years ago but is being reenacted in variation of theme throughout rural America—wherever and whenever communities and physicians need to be brought together (see Medicine at Work, The Journal, Sept. 29, 1956; Oct. 11, 1958; and Feb. 21, 1959). How did Ariton stop being a doctorless town? It was like this:

At a meeting one autumn evening, the local Lions Club decided it was high time to raise money to build a medical office. So they held a contest right then and there. Matchbooks were passed out and each member was asked to give an impromptu sales talk on the product or company imprinted on the cover. The three presentations adjudged best were delivered by E. L. Fralish, Kyser Wilson, and D. B. Richardson. Their prize was one shoelace apiece—with the mission of parlaying these stringy items into an initial campaign fund. One was sold for $1

Placement Straws in the Wind

What is the current status of doctor demand and supply? While not complete, some indication may be found in the following recent reports from the A. M. A. Physicians Placement Service:

—Industrial relations department representatives for defense project construction firms in Greenland, for the DEW (distant early warning) line in Canada, and for an electronics and missile firm in the U. S. are looking for medical directors at salaries of up to $25,000.

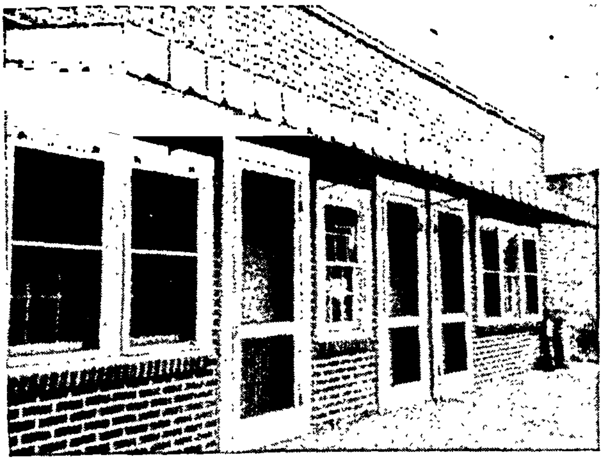
—Correspondence and observation in the past year indicate that a number of highly trained young surgeons are being forced into "quasi general practice," possibly because of a saturation of the specialty of surgery. The reason and extent of this condition cannot be determined for certain at this time; however, distribution studies, by specialty, are now under way.

—Liaison with the A. M. A. Council on Medical Education and Hospitals now is being refined so that medical schools and physicians with academic positions in mind may be brought together through the placement office, which functions under the Council on Medical Service.

and the money bought more laces, which then were sold for amounts ranging from a dime to a dollar. Within weeks, the "Shoestring Committee," with the help of merchants contributing other goods for sale, had a $300 kitty—plus a lot donated by the town for a medical office site.

Now came the supersalesmanship. Lions Club members decided to hold an auction unlike any other ever conducted anywhere. Townspeople would be invited to "bid" for the right to finance unseen assets of the unbuilt clinic building. This novel idea captured the imagination of Ariton—and it worked. Bidding $100, one citizen won over his neighbors for the "privilege" of giving and installing windows of the clinic. Another $100 offer entitled the bidder to dig necessary ditches for construction. A third $100 bid included the privilege of drawing up blueprints of the building. Other offers brought both money and materials for naming the clinic and installing a water fountain outside (see photo).

"It was the screwiest auction I ever attended," said one Lion, "but it sure caught on. Everybody, it seemed, was scrambling for the right to give money and be identified with the project in some special way. We soon had a seven-room clinic."



View of the medical office "built on a shoestring" in Ariton, Ala. Note, at lower right, water fountain, which was installed by a townsman who outbid his neighbors for the privilege of "sponsoring" it.

Lions Club members then began seeking a doctor to occupy it. One physician moved in after the A. M. A. Physicians Placement Service and the Medical Association of the State of Alabama went into action. But last year he moved away for health reasons and because the office was too far from his home. So again medical association help was sought—and last fall the townspeople turned out to welcome Dr. George M. Malouf, a graduate of the University of Vermont College of Medicine.

His may be the only medical practice in the nation that had its start, literally, on a shoestring.

When Lions Roar

Lions Clubs in many parts of the country have taken the initiative (along with Ariton; see story) to improve medical service. Because their activity has brought physicians to so many doctorless towns, closer liaison now is being established between Lions International and the A. M. A. Physicians Placement Service. Following are excerpts from letters to the placement office from local Lions Clubs:

"Our Lions Club has for its major project this year the procuring of a country doctor for our community. We have already procured a lot and we anticipate no trouble at all in financing the project as the public is very enthusiastic..." (Kentucky)

"Our Lions Club is greatly concerned about the medical services and facilities available to the people and industries of our community..." (Pennsylvania)

"Thanks to your placement service, we were able to secure a full time resident doctor, to take charge of our new Lions Club Medical Center..." (Indiana)

Replies to almost all such inquiries refer to the appropriate state medical society and include two A. M. A. booklets, "A Doctor in Your Community" and "Community Efforts Provide Medical Facilities." In addition, Miss Dorris Webb, the staff assistant at A. M. A. headquarters in Chicago, may suggest that the Lions Club obtain the free loan (through its local medical society from the A. M. A. film library) of a 28-minute color movie, "A Citizen Participates." It tells of a girl, ill in a Kansas town where there is no physician, and how members of a fraternal group go about bringing in a resident physician.

So far, reports Miss Webb, none of the Lions Clubs which showed the film have let out a peep about the fraternal group involved. It is Kiwanis, which helped make the movie in its own continuing efforts to improve medical service in communities.

Medical Electronics—The Fruitful Marriage

The patient is placed in position, the technician makes minor adjustments to his equipment, and then steps behind his shielding screen. . . .

When he sets his timing switch, the x-ray technician will be bringing into play the results of more than a half-century of cooperative effort between physicians and engineers that has resulted not only in highly refined radiological devices, but a host of other electronic marvels (see Medicine at Work, The Journal, March 21, 1959).

The debt that medicine owes to electronic engineering was cheerfully acknowledged this month by Dr. Gunnar Gundersen, A. M. A. President. Writing in *Electrical Engineering* on the occasion of the 75th anniversary of the American Institute of Electrical Engineers, he stated: "The progress of science and medicine over the last century has been hand-in-hand, each benefiting from the other's discoveries and developments, and ultimately helping mankind."

Dr. Gundersen wrote that modern x-ray units not only provide better and more discriminatory diagnostic help than earlier ones, but also decrease the amount of radiation the patient receives.

Some Views of Lawyers on The Physician as a Witness

Attorneys are as interested as physicians in improving interprofessional relations, judging by letters accompanying early returns to a questionnaire being used by the A. M. A. Law Division. In addition to filling out the four-page form, a number of lawyers spoke their minds on matters of mutual interest to both professions:

On Doctor-Lawyer Rapport—

"A doctor in general practice is usually not familiar with court trials and is somewhat handicapped in that he has to be taught how to handle himself in the trial of a case. . . . Some type of course should be taught at medical schools—if it is not already—to give some actual experience in testifying in a mock trial."

On Legal Theory—

"The essence of the American system of jurisprudence is the adversary character of the proceedings. A system under which—through vigorous contest—we seek to arrive at the truth. Lawyers accept this as a matter of course . . . yet the physician accepts the critical analysis of his testimony as a personal affront."

On Fees—

"With a large number of doctors, the attitude seems to be that they are doing an attorney a favor to appear in his case. From the defendant's standpoint, this is not true. Insurance companies are willing and do pay whatever reasonable fee is charged, and the doctors in turn should be willing to devote such time as is necessary to the proper presentation of the case."

On Differing Points of View—

"The physician's skills and training are oriented to minimizing the residual disability after the patient has had the maximum benefits of treatment. The plaintiff's attorney, in the role of advocate, must maximize the injury so that in our adversary system of justice the client's best possible case is made out. It is the duty of the defense to minimize the damage, so consequently the physician and the defense normally have common objectives."

Doctor Meets Attorney

Medicine and Law—Common Goals But Few Pat Answers to Problems

American jurisprudence is based on the adversary system—a partisan contest in which discovery of the truth is expected to result from the pleadings of opposing points of view. This same system was applied at a Washington conference last month when nearly 500 attorneys and physicians met to hear two-sided discussions of subjects in which medicine and the law have common interests.

Topic selection was varied, ranging from a sober evaluation of narcotics addiction to a humorous account of the presumed woes of a medical witness undergoing cross examination. The Washington session was the first of three similar regional meetings sponsored by the A. M. A. Law Division. Two more were scheduled for early this month in Cleveland and Salt Lake City.

Physicians who dread the thought of appearing as a medical witness through fear generated by tales of "ruinous" cross examination can relax, according to Irving Goldstein, professorial lecturer in trial technique of Northwestern University Law School. "I searched the entire country for documented examples of such technique to be included in a legal text," he said, "and I ended up with only five that were usable. A typically devastating question was 'Have you ever made a mistake, doctor?' "

Noting that law students are advised never to cross examine an expert in his own field, Goldstein said: "A physician who goes into court prepared to tell the truth, and who does not exaggerate his background and experience has nothing to fear." He warned, however, that the opposition will probably be well prepared on the medical subject in point and that the physician should review his own records, x-rays, and the medical literature prior to his appearance.

Impartial or Infallible?

Impartial medical testimony—that provided by an expert chosen by medical societies and appointed by the court—is another area in which the conference audience heard differing points of view.

G. C. A. Anderson, a former president of the Maryland State Bar Association, said impartial medical panels are the result of numerous cases in which conflicting medical testimony was presented by physicians "selected not for their medical qualifications or objectivity, but principally for their personality, manner of testifying, and jury appeal."

Metropolitan New York uses a rotating panel of expert witnesses available for call by the court to make pretrial examinations in matters of medical dispute. In Baltimore, a somewhat different plan is in effect. There the names of three experts are submitted to the parties in contest and they are asked to agree on one. If they cannot, the court makes the choice.

Drugs and Doctors

What is the physician's legal position if he prescribes narcotics for a patient who is an addict?

Federal law—and that of most states—limits the dispensing of narcotics by a physician to that done "in good faith and in the course of professional practice only." The catch comes in defining the phrase.

In 1922, the U. S. Supreme Court upheld an indictment alleging that a physician gave an addict prescriptions for 150 grains of heroin, 360 grains of morphine, and 210 grains of cocaine for use over a period of several days.

Then in 1925, the court reversed the conviction of a physician who had been charged under an indictment involving "four small tablets of morphine or cocaine."

In neither case was it alleged that the defendants failed to prescribe in the course of good professional practice.

The Joint A. M. A.-A. B. A. Narcotics Committee report of 1958 states: "There must be a new determination of the limits of good medical practice in the treatment of drug addiction, and an objective inquiry into the question whether existing enforcement policies, as well as existing laws, have unduly or improperly interfered with good medical practice in this area."

The trouble with all such plans, argued attorney Elwood S. Levy of Philadelphia, is that they "presuppose that medicine is an exact science." He said: "No fair-minded man can deny that in a substantial number of cases equally competent and equally honest physicians can and do disagree . . . It seems obvious that to label a doctor as impartial does not for a moment mean that he is right. . . . [Yet] by designating a medical witness as court appointed and impartial, the court has in effect cloaked him with the robe of infallibility and imports that his conclusions are more worthy of acceptance than those of his medical bretheren who have not been thus *distinguished*."

Rule of Sympathy

The extension of the legal doctrine of *res ipsa loquitur* ("the thing speaks for itself") was characterized by R. Crawford Morris of Cleveland as "the rule of sympathy." The fallacy in extending the application of this rule, he said, is that when a bad result follows an operation it is presumed that the reason for the bad result must be some negligence on the part of the surgeon.

Standard legal philosophy is that he who affirms must prove, but the extension of *res ipsa loquitur* in malpractice cases, Mr. Morris argued, "hurls the doctor into the lion's den." He said: "It makes the physician an insurer of perfect results, and deprives him of his right to have his conduct judged by other physicians fully aware of the facts he faced at the moment of his decision."

This view was disputed by Hugh Head Jr., an Atlanta attorney, who said the rule had been invoked in such obvious cases as that in which the surgeon operated on the wrong patient, where the patient was given 10 times the proper amount of anesthetic, and where an electric needle being used to remove skin growths had set fire to alcohol used as an antiseptic. The physician, in effect, he said, contracts to do his work well and is held liable only when he has broken his faith.

Both Morris and Head agreed that the reluctance of physicians to testify against their peers had made the courts tend to sympathize with plaintiffs. "Doctors must realize," Mr. Morris said, "that they cannot have their cake and eat it too. If they refuse to testify, courts will provide other means of redress."

Enforcement or Education

In the discussion of narcotic addiction, Alfred Tennyson, chief counsel for the U. S. Bureau of Narcotics, voiced the Bureau's long-held belief that strict enforcement of laws against the sale or purchase of narcotics for other than medical or scientific use was the best way to meet the problem. He said that experiments with big city drug clinics in the early 1920's had produced "no evidence of cures or reduction in illicit drug traffic." "Present methods," he said, have reduced the addict ratio in the general population from 1 in 400 in 1915 to 1 in 3,500 in 1958. He said he was dismayed to note that "some members of the medical profession" have sponsored a plan whereby government-operated clinics would supply the drug addict with narcotics while attempting to "persuade" him to undergo treatment and rehabilitation.

Tennyson's view was opposed by E. J. Dimock, Judge of the U. S. District Court in New York, who said: "If severe laws have had any effect on the [drug] traffic it has not shown up in our court." Judge Dimock was a member of the Joint Committee of the American Medical Association and the American Bar Association which undertook a study of the narcotic problem. He said the Committee found that not enough was known to support more than one or two conclusions. One recommendation was that the two parent organizations study further the outpatient experimental clinic plan.

Painless and safe withdrawal procedures are now in use at federal narcotic hospitals, he said, "but treatment that an addict gets there is of little help to him outside. We must learn how to help our fellow human beings to live without resorting to this destructive evasion in a world full of temptation and strains."

Judge Dimock advocated the prevention of first contact as the ideal solution to the narcotic problem. He said: "If none of us had taken that first glass of beer, we would never have had that how-long-has-this-been-going-on feeling."

Psychotherapy Is Medicine

The application of psychological methods in the treatment of illness is a medical function. Any physician may utilize the skills of others in his professional work, but he remains responsible, legally and morally, for the diagnosis and for the treatment of his patient.

When a resolution containing that statement was adopted jointly by special committees of three major professional groups nearly five years ago there already was evidence that a few nonphysicians were practicing medicine by engaging in psychotherapy. "Psychotherapy is a form of medical treatment and does not form the basis for a separate profession," the resolution went on to state, adding, however: "The medical profession fully endorses the appropriate utilization of the skills of psychologists, social workers and other professional personnel in contributing roles in settings directly supervised by physicians."

Now there are indications that more and more nonphysicians, not content with merely using psychological understanding in carrying out their professional functions, are attempting to diagnose and treat individuals by psychotherapy. The indications are so ominous, in fact, that the A. M. A. Council on Mental Health (which issued the 1954 joint resolution, along with the American Psychiatric Association and the American Psychoanalytic Association) discussed the problem at length during a meeting in Chicago several weeks ago.

Council members at their Feb. 21 meeting cited reports from colleagues as well as patients, in an attempt to clarify and reaffirm the resolution for the benefit of the public and the medical profession. Several of them expressed the opinion that it should be unlawful for a nonmedically trained psychologist to engage in the independent practice of psychotherapy, and unethical for a physician to refer patients to such an individual for treatment of nervous, mental or physical disorders.

At the same time, however, they applauded the functions of psychologists in medical settings, for psychodiagnostic testing, and for analysis and counselling in education, vocations, aptitudes and job placement. As one member summed up the discussion:

"It cannot be too strongly emphasized that the unavailability of a specialist in nervous and mental diseases is not sufficient justification for referring a patient to a nonmedical specialist for treatment. The physician should himself treat such a patient, and try to obtain or provide neuropsychiatric services locally in the future. To do otherwise only serves to compromise ethical practice and to lower the levels of medical care."

More Ammunition Against Alcoholism

New onslaughts upon alcoholism as a massive disease problem (see Medicine at Work, The Journal, July 19, 1958) were indicated at the recent meeting of the A. M. A. Council on Mental Health. Members expressed their approval of a suggestion that the Woman's Auxiliary consider alcoholism as a major project for attack in 1959. The Council also approved an outline which had been suggested by its Committee on Alcoholism as a guide for medical schools, which already are integrating alcoholism as a subject in prevailing curriculums.

Medical Students and Religion

How do tomorrow's physicians relate their religious attitudes to the study of medicine?

In an effort to find out, 208 students enrolled at the Southwestern Medical School in Dallas were asked recently to reply to a multiple-choice questionnaire. These are some sample findings:

"Do you consider yourself a religious person?" No, said 21 students, but 129 considered themselves to be at least "slightly religious."

"What about the study of medicine—is it making you more religious?" Ninety-one thought it was, 88 said it was not, and 21 thought it was making them "less religious."

In assessing the influence of religious considerations on their desire to enter the medical profession, 117 concluded there had been no such consideration, while 75 thought that there had. Nine out of 10 thought a religious nature would add to the effectiveness of a skilled medical practitioner.

Asked, "If an indicated medical procedure conflicted with your patient's religious beliefs, would you still urge the procedure?" 140 replied affirmatively, although when asked to comment, most said they would attempt to explain the necessity, and try to obtain consent.

Results of the survey were published last February in the *New Physician* by two medical students, James A. Hall, and Daniel Gruver. The authors reported that comments accompanying the returned questionnaires emphasized that these medical students, while generally considering themselves religious, disliked casting their beliefs in conventional forms. "My belief now boils down to the Superior Being, brotherhood, and compassion," one said. Only 27% said they believed in all the creeds and dogmas of their religion (see Medicine at Work, The Journal, April 13, 1957).

DÉBRIDEMENT IS PARAMOUNT

GUEST EDITORIAL

John O. Goodsell, M.D.

COMPOUND fractures are emergencies. They require treatment promptly, for time is of the essence. Débridement is the keystone of the treatment.

The ideal treatment of the compound fracture devolves logically in a well-established chronological order. This begins with adequate first aid at the site of the accident, essentially splinting. Rapid, but safe, transportation to the place of definitive treatment ensues. Appropriate assessment of the victim's general well-being and measures for assuring its stability begin with first aid and are intensified on arrival of the patient in the emergency room. Local injuries are quickly but carefully evaluated. They are then treated and the all-important débridement performed in the case of compound fracture. Finally immobilization of the fracture is accomplished by whichever of many possible methods is best suited.

Why is débridement paramount? This can best be answered by observing that, while all infected wounds are at least unfortunate, infected fractures are catastrophes. No other single facet in the care of a compound fracture is so important in the prevention of infection as débridement. This principle has been irrevocably established for decades, but must frequently be "rediscovered."

Eaton [1] said in reference to débridement of compound fractures in World War II: "In spite of the experience gained in World War I, this lesson had to be learned all over again in the early part of this war." The literature of World War II is replete with references to the imperativeness of débridement. Few improvements in humanity result from war. It would be a pity if the costly lesson in proper débridement of compound fractures were not indelibly stamped in the consciousness of all who assume the treatment of trauma.

How débridement deters infection is made clear by Watson-Jones in his textbook "Fractures and Joint Injuries." [2] Débridement is the proper toilet of a contaminated wound, including removal of all tissue which is dead. Germs thrive in necrotic tissues which form a barrier between them and the body's natural defenses. Healthy vascular tissue can, given proper opportunity, deal successfully with germs.

Débridement should be performed as soon as the patient's condition will allow it. There is a "golden period" of six to eight hours from the time of injury when the wound may be considered merely contaminated rather than infected. After that the wound must be treated in anticipation that infection has supervened, and débridement is of progressively less benefit. By that time drainage and compresses may be more appropriate, alone or with débridement.

Some situations delay immediate débridement. Other injuries most often force temporary postponement. However usually such factors can be improved rapidly enough to stay within the "golden period." Shock from blood loss is the most common deterrent. It behooves the surgeon always to treat shock as vigorously as possible, first to preserve life and next to preserve the limb by early débridement. To save the patient's life may be heroic, but the surgeon's fatigue must be ignored until the fracture has also received its adequate treatment. The reward for such tenacity is great: avoidance of prolonged, sometimes seemingly endless, treatment of chronic osteomyelitis.

Some injuries, e. g., to the brain, lungs, liver, or spleen, may not permit débridement at the ideal time. All injuries to the head, chest, and abdomen do not automatically prevent proceeding, however. We must exert energy here also to distinguish the type present. Conceivably the presence of disease unrelated to the accident may interfere, e. g., diabetes or heart disease. Again we must distinguish when these things might reasonably be ignored or improved sufficiently to deal with the local injury.

Orthopedic surgeon, Saginaw, Mich.

The technique of proper débridement is dealt with in detail in various textbooks. The principle is excision and removal of all foreign material. This includes dead tissue, because it too is foreign. Skin removal should be minimal; usually a 2-or-3-mm. excision of the wound margin suffices. All dead fat, fascia, and muscle must go; left behind they can only liquefy and become a culture medium. Vessels and nerves should be identified and protected. Bone should not be removed unless totally detached from soft tissue. Copious irrigation with sodium chloride solution is invaluable in removing small bits of debris.

The use of internal fixation is somewhat controversial and in the opinions of some writers never applicable in compound fractures. Properly selected, nevertheless, internal metal appliances have been used in many such cases by many surgeons without significant complications.

To close or not to close is also a question. Opinions here vary from never to not over eight hours after injury, and even longer. Individualization is needed here too, with such things as amount and type of contamination, amount of skin remaining, and time after injury being important. There is fairly general agreement that if closure is elected, it should be of skin only, never fascia.

Antibiotics undoubtedly contribute to the success of treatment of compound fractures. It has been written again and again that the availability of these drugs does not alter fundamental surgical principles. Débridement of compound fractures is fundamental and cannot be eliminated nor even minimized by the use of antibiotics. A review of the World War II literature on compound fracture reveals a widespread wave of enthusiasm for placing sulfonamide powder in these wounds. One can scarcely doubt in the face of practically universal approbation that this helped. But this probably coincided with progressively better débridement. The ranks of the sulfonamide sprinklers are certainly smaller than they were.

To summarize, in the treatment of compound fractures débridement is paramount. It should be done as soon as possible, with special effort to do it less than eight hours after injury. Rapid treatment of shock and other delaying conditions should be carried out. The availability of antibiotics does not decrease the necessity of débridement, nor even the extent of débridement. Rapid, energetic treatment of a compound fracture is certainly rewarding.

Some of the ideas expressed herein are based on the observations of the late Dr. Sylvester J. O'Connor.

MENTAL HEALTH WEEK, APRIL 26-MAY 2

The observation of Mental Health Week once again reminds us of one of the largest public health problems confronting the United States—mental illness. While the exact incidence of emotional disorders is not known, the rejection and discharge figures for psychiatric disorders in the armed forces in World War II, the current rates of hospitalization for the mentally ill and retarded, and the problems of alcoholism, narcotic addiction, juvenile delinquency, and broken marriages give some indication of how large the problem is. Physicians in general practice and internal medicine repeatedly have estimated that one-third to one-half of the patients they see have disorders which are primarily psychogenic or which are complicated by emotional factors.

The level of care of many patients in mental institutions is indeed low. It is reported that in some mental institutions with over 1,000 patients there is but one psychiatrist to provide treatment. The disproportion between the level of care given the hospitalized mentally ill patient and that given the patient hospitalized for a physical illness is one that medicine must strive to eliminate.

More research on the causes of mental and emotional illness and on more economical and more effective methods of treatment is urgently needed. What is known about prevention should be implemented as soon as possible and over as broad an area as possible. Physicians should be as capable of diagnosing mental illness as they are of treating uncomplicated medical or surgical illness. If the training of the physician does not achieve this, his training needs to be reexamined and changed. The training of the psychiatrist bears inspection also. He has tended to isolate himself from his medical colleagues and thereby to forego the advantages that collaboration and cooperation provide.

Now that great strides have been made in the prevention and treatment of infectious diseases, perhaps we can give more attention to mental illness and solve this serious problem, whether by biochemical, physiological, or psychosocial means.

JOURNAL INDEX

The index to volume 169 of The Journal will appear in the May 9, 1959, issue. Those who wish extra copies of the index may receive them, without charge, on request to the Order Department, American Medical Association, 535 N. Dearborn St., Chicago 10.

COUNCIL ON MEDICAL SERVICE

CHRONIC ILLNESS SERVICE CENTER OF SAN FRANCISCO

The Chronic Illness Service Center of San Francisco was established in October, 1950, as the result of two years of study and planning by a special subcommittee of the Social Planning Committee of the Community Chest. This subcommittee, after reviewing the problems of the chronically ill both nationally and in the San Francisco area, recommended a two-year demonstration program to test the feasibility and value of a central information-gathering, coordinating, and referral agency for the city's chronically ill. Originally supported by foundation funds and later by the United Community Fund in 1955 the Chronic Illness Service Center of San Francisco began operations directed toward the following objectives: (1) to promote the development of a coordinated community-wide program for adequate care of the chronically ill; (2) to assemble and make available information regarding the unmet needs and problems of chronic illness; (3) to assemble, study, and make available information on existing community facilities and resources for the chronically ill; (4) to stimulate public interest and understanding of the problems of chronic illness and its prevention and control; and (5) to assist organizations in planning facilities and programs for the chronically ill.

Organization and Operation

The original staff of the service center, which was housed rent-free in the Community Chest Building, consisted of a director and an office secretary. A medical social worker was added to the staff in August, 1952. The center functions under the guidance of a 21-man board of directors, who are familiar with the community and its resources and specifically concerned with the problems of chronic illness. Additional consultation and guidance is provided by a technical advisory committee, representing various professional groups with a knowledge of the key fields related to chronic illness.

The director's duties, in addition to over-all supervision of the administrative and program activities of the center, include liaison with the board of directors and the technical advisory committee, interpreting agency policies to the community and professional groups, consultation with individuals and groups planning resources for the chronically ill, preparing reports on the individual and community problems of long-term illness, and the planning of meetings and educational activities for specific groups.

The medical social worker is responsible for the day-to-day operation of the information, counseling, and referral service. Consultation with and referral of patients or other persons seeking suitable facilities for care is her continuing responsibility. She secures and maintains current information on the various facilities and resources for long-term care in the community and makes this information available to persons and organizations who need assistance in planning care for chronically ill or disabled patients. She also acts as a consultant to the operators of nursing homes and other long-term care facilities on administrative policies, needs of the long-term patient, and ways of improving care.

The office secretary, under direction, is responsible for the management of the office and the clerical-administrative details inherent in the center's operation, maintaining files, records and correspondence, and preparing monthly statistical reports. She also acts as receptionist and telephone operator.

The center occupies about 450 sq. ft. in the Community Chest Building and is divided into three offices. Inasmuch as the majority of referrals and information can be given by telephone and all office interviews are by appointment, the lack of space has not presented a serious problem as yet. Files maintained in the office include detailed data on proprietary nursing and boarding homes and other facilities and services currently operating in the community (this information is usually obtained by a questionnaire followed by a visit to the facility) and complete individual case records for all persons requesting services, which are divided according to new requests, recall cases, and persons seeking information not related to a specific patient.

Services to Patients

From the beginning, it was felt that emphasis should be placed on counseling, guidance, and referral services to individual patients and others seeking information and that in this way insight would be gained into the over-all planning, coordinating, and educational services needed in the community as a whole. In accordance with this policy, services were made easily available and individuals requesting help were accepted without being

This is part of a series of articles, prepared by the Council on Medical Service, on chronic illness information centers in various parts of the United States.

obliged to undergo detailed investigative procedures. However, there was no emphasis on case-finding activities nor on publicity concerning the center's existence. An announcement letter was mailed to other agencies notifying them of the center's availability, and two articles describing the center were published in the San Francisco Medical Society Bulletin. No organized follow-up is made of patients to see whether the solution or the placement suggested has been completely satisfactory in each case.

TABLE 1.—*Persons Served in 1954, 1955, and 1956*

Year	Patients, No. New*	Recall†	Other, No.‡
1954	788	360	185
1955	1,087	641	276
1956	1,329	902	208

* Patients known to center for first time

† Patients who have received previous service from center.

‡ Requests for service not related to specific patient.

From its inception in October, 1950, to the end of 1956, the center provided services to 7,037 individual patients or other persons. During the calendar year 1955, 1,728 patients sought help at the center, an increase of 51% over 1954 (641 of these patients had received service previously from the center; the remainder were new referrals). Table 1 shows the number of services requested during the years 1954, 1955, and 1956, divided according to new and recall cases and requests not related to an individual patient. Table 2 shows the referral sources for both new and recall patients during the year 1956.

Of the 1,329 new patients referred to the center in 1956, almost 60% were between the ages of 65 and 85. The average patient age has been steadily rising since the center's inception and was 71.6 years in 1956. Almost twice as many women as men are referred to the center. About 63% of the patients were widowed or single, 36% lived alone, and 26% lived with relatives. An increasing percentage of ambulatory patients are being referred to the center. During the early experience one-half of the patients referred were bedfast, while in 1956 this percentage has shrunk to ⅒ of total referrals.

Factors which might explain this trend have been an increased bed capacity in the voluntary chronic disease hospitals, the setting aside of 20 new long-term beds in two general hospitals in the city, and, on a broader scale, a growing recognition on the part of agencies and individuals that bed care is not always the best answer to needs of the long-term patient. Table 3 shows the characteristics of patients newly referred to the center during 1956 by age, degree of disability, living arrangements, financial status, and other factors.

Needs of Patients

During 1956, requests for 24-hour nursing or supervisory care accounted for a little over 60% of all needs for service among newly referred patients. The next most frequent requests were for counseling and for some type of housekeeper-attendant service. Other requests were for general information on facilities and resources for long-term care, information on a specific facility or resource, or for consultation. Table 4 shows the nature of requests for service received by the center during 1956, divided by new and recall patients.

Problems and Developments

In answering these requests and in attempting to find and effectively utilize existing services and facilities, the center has brought into clearer focus some of the more pressing problems in meeting chronic illness needs in San Francisco.

One of the major problems encountered by the center has been the inability of many patients to pay for the type of care they need. The trouble lies not so much in a shortage of good nursing homes, boarding homes, and other long-term facilities as in the fact that the rates at these better facilities are too often beyond the patient's ability to pay. This has been true both for patients seeking 24-hour nursing care and for those seeking domiciliary or boarding home facilities.

The center has also found that there is not enough provision for rehabilitation in the various long-term facilities. In the proprietary nursing and boarding homes the emphasis given to rehabilitation varies widely and reflects the philosophy of the operator, his idea of the rehabilitative potential of the elderly chronically ill person, and the economic effect such services will have on his own business. Consistent physical and occupational therapy and diversional programs are for the most part lacking in proprietary facilities for long-term care, where the lack of adequate staff and the cost of such services prohibit organized efforts.

TABLE 4.—*Nature of Patient Requests, 1956*

* Applies to recalls only.

Considerable overlapping and duplication of function exists among the various chronic disease facilities and services. No facilities especially adapted to the needs of the younger chronically ill adult presently exist. There are limited subsidized convalescent resources for women and none for men in the city.

Another problem has been obtaining efficient, reliable homemaker-attendant services. Previous attempts at homemaker service for the city's chronically ill have been sporadic and temporary in nature, and there is no permanent, established program of this type at the present. (A limited demonstration Homemaker Service primarily for chronically ill and aged persons was established on May 1, 1957.) As a result, the cost of obtaining reliable full-time attendant service has been prohibitive for many families, and the type of consistent, dependable part-time help which would make secure family planning possible has been equally hard to find.

Another need that has become increasingly clear as operations progressed is for more counseling specifically geared to the chronically ill, embracing the many problems that accompany long-term sickness or disability, such as dwindling finances, family attitudes, living arrangements, and the psychological impact of long-term dependency. The center reports that there has not been too much change in the types of patients or problems since its inception, but there has been encouraging progress in the community's thinking about chronic illness. Some change is evident in the "hopeless" pattern of patient management and more emphasis is being placed on rehabilitation.

Services to the Community

As the result of its contacts with patients and its work and findings in the community, the center has been able to implement and participate in broader community planning for service to the chronically ill. In addition to maintaining complete information on the services, rates, and facilities in commercial nursing and boarding homes in the San Francisco area, the center has sponsored two institutes for nursing and boarding home operators. The second in a series of five meetings, held in the fall of 1955 by popular request of the operators, featured demonstrations and discussion of new techniques in patient management. The center also continues to provide consultation on standards of care and operating practice to operators on a day-to-day basis, and to sponsor a closer working relationship between nursing and boarding homes and hospitals, physicians, and other related organizations.

Partly as a result of the center's recommendations, and with its informal participation, a home-care plan for the chronically ill of San Francisco is in operation at the Mount Zion Hospital, and the Center has continued to stimulate the formation of other such programs, particularly under public auspices. Finally, the center continues to bring together representatives of the voluntary health organizations concerned with long-term illness and has provided these organizations with a basis for joint planning and action.

MEDICINE AND THE LAW

AVERTING PROFESSIONAL LIABILITY ACTION

Samuel Polsky, Philadelphia

There are three fallacious attitudes common among doctors that lead to professional liability action. First is the belief that diagnostic and surgical skills are the chief safeguard against a malpractice action; second, that being a good Samaritan is good medicine; and third, that a just cause is a good cause. These virtues may win lawsuits, but they seldom prevent them. Being a defendant in a malpractice action is never a happy experience, no matter how sweeping the ultimate victory may be. Before I am branded as a devil's advocate or dismissed as a complete legal cynic, let me still some of the free-floating anxiety that the word "malpractice" seems to arouse in physicians by stating that the bulk of malpractice actions in the United States are readily preventable.

For proof of that statement one need only look at the medical quack. Of the tens of thousands of malpractice actions that fill our law reports, how many are directed against quacks? Disconcertingly few. What accounts for this peculiar state of affairs? It cannot be explained away by saying that there are relatively few medical quacks left; that may be true in some parts of the country but false in others. The efforts of medical societies and the work of the United States postal authorities, the Pure Food and Drug Administration, and other agencies testify to a continuing fight against new medical quacks as fast as the old ones are put out of business. But almost without exception public or quasi-public agencies such as the medical societies conduct the fight. Rarely does the individual victim bring a malpractice suit against the medical quack.

The reason for this is not difficult to find. The only skill that the quack has to sell is the ability to establish and maintain rapport with another person. Medical skill is completely absent, yet so are malpractice suits.

As a case in point, some years ago in Pennsylvania a self-styled plastic surgeon set up in business. He straightened noses by injection of wax. Unfortunately, on hot July days, his patients found their noses melting. They did not run to their lawyers, however. There was no need to; day or night their "doctor" was available with sympathy, consideration, and understanding and ultimately, of course, with more artistry in wax. The medical society fought him through one court after another, but not even this publicity was enough to break his immunity from malpractice attacks by his victims.

His single stock in trade was an excellent bedside manner, reflected in a continuing high degree of rapport with his patients. This was enough to prevent malpractice actions despite his complete absence of formal medical training. This is not to suggest that medical schools establish a clinical professorship in medical quackery to teach the skills of rapport. All too often, however, this skill tends to be dwarfed by other professional skills. Perhaps, also, the association of this one skill with the quack leads to its depreciation in the hands of the reputable physician. To some extent the demands of a busy practice accomplish the same result, and specialization exacts somewhat the same toll.

I suggest that the modern surgeon exhibits little warmth in establishing the physician-patient relationship. May I also suggest that it is this factor, rather than the risks inherent in surgery, which so often makes the surgeon the target of malpractice litigation? The risks of surgery are not to be denied, of course, but that very fact conditions the patient to accept an untoward result with greater tolerance. If I were required to state a first principle of preventive law in malpractice actions it would be that diagnostic and surgical skills are far less important than is skill in establishing a friendly physician-patient relationship. In achieving this, it seems to me that the ability to listen and simply being available to the patient are all-important.

There is a difference, of course, between being a good doctor and being a good Samaritan. The second legal pitfall leading to a malpractice action lies precisely here. The physician should exercise his bent for doing good in the highest tradition of his profession by giving of his services as freely as he likes or is able; he enters dangerous ground only when he stops practicing professional medicine in order to practice amateur economics. The warning signs and admonitory symptoms are plain. They may be summed up as hypersensitivity of the ego accompanied by subacute melancholia and manifested by Hamlet-like musings along these lines: Can the patient really afford a roentgenogram?

Associate Professor, Temple University Law School, and Director, Philadelphia Medico-Legal Institute.

Read before the forum The Doctor and His Practice, presented by the Wm. S. Merrell Company and the Erie (N. Y.) County Medical Society, Buffalo, Nov. 6, 1958.

Will he think I am just trying to squeeze another visit out of him if I ask him to come back for a follow-up examination? Is it an admission of failure if I suggest a consultation? The variations are infinite, but the basic syndrome remains one of medical insecurity largely induced by economics. It results in indecision and lack of medical action and is defensively rationalized as concern for the patient. The diagnosis is cardiovascular good-Samaritanism.

The prognosis is guarded, with possible legal complications which often take the form of a malpractice action based on failure to check routine safeguards, failure to follow up, failure to obtain consultation, failure to refer the case for observation or specialized treatment, failure to advise the patient of the risks of inaction, and sometimes even failure to tell the patient just how ill he really is.

If, therefore, I had to state a second principle of malpractice prevention it would be to diagnose and cure yourself of good Samaritan palpitations unless you would like to recite and explain your soliloquies from the witness stand to a patient you have abandoned medically. This is not overstating the case, for opposing counsel and the court will remind you (and the audience of 12 jurors) that good intentions are not the equivalent of good medical practice.

The third fallacious attitude that I would invite you to consider is that a just cause is a sound course to pursue. The history of many malpractice actions begins with the righteous indignation of a physician whose fees have not been paid by a patient who can afford to pay them. After a course of polite and then pointed reminders have failed to elicit response the matter is turned over to a commercial collection agency, whose insistence reminds the patient so often of the doctor that in time he develops at least a mild obsessive-compulsive neurosis. The obsession takes the form that the doctor is not, and never was, any good. In time this includes the view that the physician lacks skill as well as being a money-mad pirate without principles or scruples. The compulsion takes the form of a desire to talk about the persecution to all who will listen. The patient's family and friends assure him that he is right and that he looked, talked, and felt far worse after the doctor's shameful treatment and incompetent ministrations. Soon the patient thoroughly believes all this, and the obsession has become a delusion with strong paranoid coloring. By the time he sees his first lawyer he is thirsting for primitive retaliation. After being told he has no case, he broods over the deficiencies in his cause of action and eventually comes to discover the missing elements. The next lawyer he sees has a case that spells legal indignation over medical malpractice, and suit is started. Or the physician may sue for his bill and by a similar, perhaps more rapid, process find himself faced not only with defense of malpractice but a counterclaim or countersuit for damages.

This history can be altered by a rather simple bit of preventive law: A just cause must not be hurried on its course. The statute of limitations for malpractice actions is far shorter than the limitation period for debts or contracts. Usually the malpractice action must be brought within one or two years of the time of alleged injury, while the debt or fee is not outlawed for some six or seven years from the time when it was contracted. Patience, in waiting until the malpractice period of limitations has run out, will not only restrain unwarranted suits of a purely retributive nature but may even result in peaceful, perhaps piecemeal, payment of the fee.

As a final item of preventive law I urge that writing be retrieved from among the lost arts of medicine. If a patient refuses to follow advice, write and either tell him to get another doctor within a reasonable time or inform him that you cannot and will not be responsible for his treatment if he refuses to take your advice. Also, if you have a seriously ill patient who requires frequent or constant care or may require emergency care while you are away on vacation or on a trip, do not rely on your answering service to do your referrals under such circumstances. A note to the patient, telling him who will be covering your practice in your absence, and a note to the other physician, describing the case and course of treatment, not only will avert malpractice actions but also may prevent serious harm for the patient. And when an experimental or risky procedure is to be tried do not rely on just the hospital release form and the patient's oral consent. His consent, after explanation of the risks, should be obtained in writing. It need hardly be added that it is wise to keep copies of these letters in your own records. The psychological value of such written communications in dissuading a patient from initiating litigation is probably greater than their probative value in court; but that, after all, is simply another way of saying that the measure is good preventive law.

While many (perhaps most) malpractice suits can be prevented, some will always remain. No profession is wholly immune from carelessness or ignorance. I urge in conclusion that, when such a situation arises in your medical community, it is not preventive law to refuse to make your honest opinion known. Refusal to testify under such circumstances involves something more important than personal convenience or lack of fortitude. It defeats justice, and degrades both law and medicine from their high estate as professions worthy of public respect.

Clinicopathic Meaning the Nephrotic Syndrome, Dr. Arthur C. Allen, Miami.

The Roentgen Diagnosis of Lesions of the Spine, Dr. John Arthur Evans, New York City.

Pediatric Anesthesiology for Head and Neck Surgery, Dr. M. Digby Leigh, Los Angeles.

Anticoagulants: "How Come, How Good, and How Now?", Dr. Edgar A. Hines Jr., Rochester, Minn.

The Early Management of the Burn Patient, Dr. Curtis P. Artz, Jackson, Miss.

Dr. Louis M. Orr, Orlando, Fla., President-Elect, American Medical Association, will present an address on "Time for Medicine's Re-Entry" at the general session, May 18, 11:50 a. m. Social events will include alumni dinners. Scientific and clinical exhibits are planned. President of the association is Dr. Lee Howard Sr., Savannah. For information, write Mr. M. D. Krueger, 875 W. Peachtree St., N. E., Atlanta, Ga., Executive Secretary.

IDAHO

Fifty-Year Physicians Honored.—"Fifty-Year Certificates" were mailed in December to 27 Idaho physicians who have been in practice for a half-century or more. A personal letter from Dr. Hoyt B. Woolley, Idaho Falls, who conceived the idea of honoring these physicians, accompanied each of the certificates. Receiving the honors were Ethel P. Westwood, William F. Tyler, and Floyd G. Wendle, Sandpoint; Charles R. Hudgel, Fred A. Pittenger, Thomas N. Braxtan, Samuel W. Forney, and August L. Heine, Boise; George O. A. Kellogg, Nampa; Harry H. King, Montpelier; Charles J. Kinsolving, St. Maries; Dailey C. Ray, Francis S. Miller, and Minnie F. Howard, Pocatello; Robert H. Wright and Earl W. Fox, Hailey; Clifford M. Cline and Arthur R. Soderquist, Idaho Falls; Herbert C. Mowery, Wallace; John H. Cromwell, Gooding; William M. Mitchell, Parma; Harry W. Wentworth, Lewiston; Vonando G. Logan, American Falls; Edward L. Hargis, Ashton; Joseph Fremstad, El Paso, Texas; Charles W. Dill, Shoshone; and Grover C. Sherrard, Bonners Ferry.

ILLINOIS

Plan Alumni Seminar.—The Medical Alumni Association of the University of Illinois has scheduled its fourth semiannual medical seminar for Monday, May 18, preceding the Illinois State Medical Society meeting. The annual banquet will be held at the Illini Union, 715 S. Wood St., following the day's program of seminars, lectures, and clinics. Officers for 1959-60 will be elected following the banquet. Guest speaker will be Gordon N. Ray, Ph.D., vice-president and provost of the University of Illinois. The staff of the university's College of Medicine will provide the clinics and lectures and will conduct the question-and-answer sessions. The seminar is co-sponsored by the College of Medicine and Medical Alumni Association. All alumni and their guests are invited. For information write Dr. Louis R. Limarzi, associate professor of medicine, Room 216, University of Illinois Research and Educational Hospitals, 840 S. Wood St., Chicago 12.

Quincy Physicians Assist New Educational Society.—On March 20 there was born in Quincy a new, nonprofit, international, educational organization called the "Society for Academic Achievement in Secondary Schools." The principal purpose of the new society is "to promote, popularize, and reward high academic scholarship achievement in the secondary schools of the United States and Canada; to guide and motivate superior and talented students to seek a college education." The society is an outgrowth of the Quincy Major Learning Program, dedicated to the guidance and motivation of the students of Quincy and Adams County to seek college education, initiated and sponsored by the Swanberg Kiwanis Foundation and the Kiwanis Club of Quincy in 1956. Community organizations, not affiliated with the secondary schools but approved by the school administrators, are being urged to sponsor the society in the secondary schools. Academic scholarship achievement awards will be given in accordance with regulations established by the society, with the secondary school principal, or his representative, responsible for the faithful observance of the regulations. Each student award recipient becomes an award member of the society for life. The criterion for award membership is competitive high scholarship achievement, especially in academic subjects. The incorporators of the society have adopted a constitution, made application for Illinois incorporation as a nonprofit organization, and elected the first board of trustees. Among the seven incorporators are Dr. Elbert Newton DuPuy, Quincy, counselor, Illinois State Medical Society, and Dr. Harold Swanberg, Quincy, secretary, American Medical Writers' Association and Mississippi Valley Medical Society. The society is being sponsored by the Medical Foundation of the Adams County Medical Society, the Kiwanis Foundation of the Kiwanis Club of Quincy, the Collegiate Educational Fund of the American Medical Writers' Association, and the Mississippi Valley Medical Society. The sponsors are nonprofit organizations, which have education as one of their objectives and each has given a grant to get the new society launched.

Chicago

Work Simplification Class for Heart Patients.—"Rehabilitation for the Homemaker Convalescing from Heart Disease," a work simplification class providing help for women patients who must take it easy, is planned by the Heart of the Home Committee, Chicago Heart Association. The first of the two planned series, held at the Museum of Science and Industry, began April 7, with classes held April 14,

MEDICAL NEWS

ALABAMA

Dr. Spies Honored.—For the first time, an "International Boss of the Year" was selected by The National Secretaries Association (International). The honor went to Dr. Tom Spies, of Birmingham, director of the Nutrition Clinic at Hillman Hospital and chairman, department of nutrition and metabolism, Northwestern University Medical School, Chicago. The award was presented to Dr. Spies during Secretaries Week, on Secretaries Day, Wednesday, April 22. Dr. Spies' background was submitted for the "International Boss of the Year" award by his secretary, Miss Margaret Owen, of the Birmingham Chapter, National Secretaries Association.

Clinical Meeting Held at the Tuskegee Institute.—The 47th annual meeting of the John A. Andrew Clinical Society was held April 12-17 at the John A. Andrew Memorial Hospital, Tuskegee Institute, under the presidency of Dr. J. D. Merida, Cleveland. Over 30 papers were presented, including the Charles R. Drew Memorial Lecture given by Dr. Hollon W. Farr. A Medical-Dental Lecture, "Cancer of the Mouth," was also presented by Dr. Farr. Panel discussions were held on "Drug Therapy of Hypertension" and "The Use of Tranquilizing Drugs." A clinical pathological conference, movie sessions, and a clinical case presentation on "Sarcoidosis–Hodgkin's Disease" were held. At the banquet April 13, Commissioner Elmer A. Carter, State Commission Against Discrimination, New York City, presented an address.

CALIFORNIA

Los Angeles Doctors' Symphony Orchestra.—This organization held its annual elections recently and the following are new officers: Dr. Lester M. Morrison, president; Dr. Jesse Younger, vice-president; William Curry, D.D.S., secretary; Dr. John Brody, treasurer; Mrs. John Brody, librarian. The Los Angeles Doctors' Symphony Orchestra is a five-year-old, nonprofit organization sponsored by the Los Angeles County Medical Association which holds weekly rehearsals and gives two symphonic concerts yearly for charitable purposes. The orchestra consists of 80 musicians, composed of physicians, dentists, and allied professionals "who have banded together in a merger of medicine and music for mutual enjoyment." A concert held Jan. 21 in Philharmonic Auditorium was given for the use of the City of Hope with Anna Maria Alberghetti as guest artist. The next spring concert is scheduled for June 6.

DISTRICT OF COLUMBIA

Dr. Bayne-Jones to Receive Award.—The Board of Directors of the Passano Foundation announce that Dr. Stanhope Bayne-Jones has been selected as the recipient of the $5,000 Passano Award for 1959. On Wednesday evening, June 10, during the convention of the American Medical Association in Atlantic City, a reception and dinner will be held at the Traymore Hotel to honor Dr. Bayne-Jones. Dr. Louis M. Orr, incoming President of the A. M. A., will speak on Dr. Bayne-Jones' contribution to the practice of medicine. Joseph C. Hinsey, Ph.D., director, New York Hospital–Cornell Medical Center, New York City, will present Dr. Bayne-Jones' contribution to medical education. This year's award is presented to Dr. Bayne-Jones "in recognition of a long and extraordinary service to science and medicine as educator and administrator in tasks of the highest importance, in all of which he has served with distinction and faithfulness." His most recent post was that of chairman of the Secretary's Consultants on Medical Research and Education, Department of Health, Education, and Welfare. The Passano Foundation was formed late in 1943, having as its sole purpose the encouragement of medical science and research, particularly that having a clinical application. It is sustained by annual contributions from The Williams & Wilkins Company, publishers of medical and scientific books.

GEORGIA

Annual Session in Augusta.—The 105th annual session of the Medical Association of Georgia will be held at the Bon Air Hotel, Augusta, May 17-20. The House of Delegates will convene May 17, 5 p. m., and reconvene May 20, 9 a. m. Dr. Paul Dudley White, Boston, will present the Association Abner W. Calhoun Lectureship, "Cardiovascular Disease in the Light of the Long Follow-Up," at noon, May 19. Papers by guest speakers will include the following:

Fire and Exposure Hazards in Hospitals and Their Control, Dr. George J. Thomas, Pittsburgh.

The Inadequacies of Routine Bleeding and Clotting Time Determination, Dr. Louis K. Diamond, Boston.

The Radiologist and the Film Processing Problem, Mr. William H. Ramey, Rochester, N. Y.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Clinicopathic Meaning the Nephrotic Syndrome, Dr. Arthur C. Allen, Miami.

The Roentgen Diagnosis of Lesions of the Spine, Dr. John Arthur Evans, New York City.

Pediatric Anesthesiology for Head and Neck Surgery, Dr. M. Digby Leigh, Los Angeles.

Anticoagulants: "How Come, How Good, and How Now?", Dr. Edgar A. Hines Jr., Rochester, Minn.

The Early Management of the Burn Patient, Dr. Curtis P. Artz, Jackson, Miss.

Dr. Louis M. Orr, Orlando, Fla., President-Elect, American Medical Association, will present an address on "Time for Medicine's Re-Entry" at the general session, May 18, 11:50 a. m. Social events will include alumni dinners. Scientific and clinical exhibits are planned. President of the association is Dr. Lee Howard Sr., Savannah. For information, write Mr. M. D. Krueger, 875 W. Peachtree St., N. E., Atlanta, Ga., Executive Secretary.

Quincy Physicians Assist New Educational Society.—On March 20 there was born in Quincy a new, nonprofit, international, educational organization called the "Society for Academic Achievement in Secondary Schools." The principal purpose of the new society is "to promote, popularize, and reward high academic scholarship achievement in the secondary schools of the United States and Canada; to guide and motivate superior and talented students to seek a college education." The society is an outgrowth of the Quincy Major Learning Program, dedicated to the guidance and motivation of the students of Quincy and Adams County to seek college education, initiated and sponsored by the Swanberg Kiwanis Foundation and the Kiwanis Club of Quincy in 1956. Community organizations, not affiliated with the secondary schools but approved by the school administrators, are being urged to sponsor the society in the secondary schools. Academic scholarship achievement awards will be given in accordance with regulations established by the society, with the secondary school principal, or his representative, responsible for the faithful observance of the regulations. Each student award recipient becomes an award member of the society for life. The criterion for award membership is competitive high scholarship achievement, especially in academic subjects. The incorporators of the society have adopted a constitution, made application for Illinois incorporation as a nonprofit organization, and elected the first board of trustees. Among the seven incorporators are Dr. Elbert Newton DuPuy, Quincy, counselor, Illinois State Medical Society, and Dr. Harold Swanberg, Quincy, secretary, American Medical Writers' Association and Mississippi Valley Medical Society. The society is being sponsored by the Medical Foundation of the Adams County Medical Society, the Kiwanis Foundation of the Kiwanis Club of Quincy, the Collegiate Educational Fund of the American Medical Writers' Association, and the Mississippi Valley Medical Society. The sponsors are nonprofit organizations, which have education as one of their objectives and each has given a grant to get the new society launched.

Chicago

Work Simplification Class for Heart Patients.—"Rehabilitation for the Homemaker Convalescing from Heart Disease," a work simplification class providing help for women patients who must take it easy, is planned by the Heart of the Home Committee, Chicago Heart Association. The first of the two planned series, held at the Museum of Science and Industry, began April 7, with classes held April 14, 21, and May 5; the second series will be held at Mary Thompson Hospital, 140 N. Ashland, May 7, 14, 21, 28, at 2-3 p. m. For reservations, write Margaret H. Brookes, Ph.D., 69 W. Washington St. (FI. 6-4675).

Personal.—Dr. Manuel E. Lichtenstein has been elected chairman of the department of surgery, Cook County Hospital. He was also elected to membership on the board of trustees, Cook County Graduate School of Medicine.—Dr. Piero P. Foa, professor of physiology and pharmacology, Chicago Medical School, will address a series of seminars at the Universities of Copenhagen, Helsinki, Edinburgh, and Milan, during April and May. He will also address an International Symposium on the Relationship of Sulfur to Diabetes at the University of Bologna.

LOUISIANA

Meeting of State Society in New Orleans.—Physicians from all 64 Louisiana parishes will meet in New Orleans May 4-6 for the 79th annual meeting of the Louisiana State Medical Society. Dr. Gunnar Gundersen, LaCrosse, Wis., President of the American Medical Association, will address the opening meeting May 4. Dr. William C. Rivenbark will be general arrangements chairman for the meeting, and Dr. Arthur D. Long Jr., of Baton Rouge, president of the Louisiana State Medical Society, will preside. Among the out-of-state guest speakers who will address scientific sessions are Dr. Edward S. Judd Jr., Rochester, Minn.; Dr. Samuel Buford Word, Birmingham, Ala.; Dr. David G. Decker, Rochester, Minn.; Dr. E. Crampton Harris Jr., Mobile, Ala.; Dr. Theodore C. Panos, chairman, department of pediatrics, University of Arkansas Medical School, Little Rock; and Elaine L. Updyke, Sc.D., Atlanta, Ga. Louisiana State Medical Society members completing 50 years of medical practice will be given special recognition at the opening meeting and be admitted to the "50-Year Doctors Club." A full schedule of scientific and business discussions will be conducted during the three-day meeting. All sessions will be held at the Roosevelt Hotel. For information, write the Louisiana State Medical Society, 1430 Tulane Ave., New Orleans.

MASSACHUSETTS

Medical History Lecture.—A new Horblit Lecture on the History of Science was inaugurated at Harvard University, Boston, by Herbert Butterfield, Master of Peterhouse and the professor of modern history at the University of Cambridge, England. "The History of Science and the Study of History" was Professor Butterfield's subject at 8 p. m., March 24, in the Allston Burr Lecture Hall. The new Horblit Lecture on the History of Science is supported by a fund established by Mark M. Horblit, of Newton Center, Harvard alumnus.

Personal.—Dr. W. Bradford Patterson, of Wellesley, has been appointed chief of professional services at Pondville State Hospital, Dr. Alfred L. Frechette, commissioner, Massachusetts Department of Public Health, has announced. Dr. Patterson will take over some of the duties of Dr. Ernest M. Daland, chief of staff, who has held this position since the hospital was established 32 years ago. Dr. Daland is planning to retire from Pondville and is turning over his duties gradually, but will continue as an executive member of the consulting staff.—Dr. Alfred Hollander, assistant professor of clinical dermatology, Boston University School of Medicine, presented "Diagnosis and Therapy in Dermatology" under the auspices of the World Medical Association before the Peruvian Medical Association in Lima, Peru, in March. He also spoke before the Peruvian Anatomico-pathological Society on "Newest Histopathological Findings in Dermatology."

Break Ground for Research Building.—Ground was broken March 2 for a 3-million-dollar medical research building for the Boston University School of Medicine. The site of the projected building is adjacent to the School of Medicine at 80 E. Concord St. and is bounded by East Concord and Stoughton streets and Harrison Avenue. President Harold C. Case, of Boston University, spoke during the informal ceremony. Invited guests included the university's four vice-presidents: J. Wendell Yeo, Ph.D., vice-president for student affairs; George A. Warmer, D.D., vice-president for university affairs; John A. Dunn, vice-president for university development; and Kurt M. Hertzfeld, vice-president for administrative affairs. Other invited participants were Dr. Chester S. Keefer, dean and director of the School of Medicine; Dr. Lamar Soutter, associate dean; Randall W. Weeks, executive secretary of the university's General Alumni Association; and Russell W. MacLaren, business manager of the university. The building, which will take 18 months to complete, will be devoted to research and clinical and basic medical sciences.

MICHIGAN

Service for Multiple Sclerosis Patients.—A consulting and diagnostic service for multiple sclerosis patients has been established at Wayne State University College of Medicine, Detroit, according to Dr. John S. Meyer, chairman, department of neurology. The service is sponsored by a $20,000 grant from the Michigan Chapter, National Multiple Sclerosis Society, a United Fund–Torch Drive Agency. Dr. John T. McHenry, associate professor of neurology, is director of the new Multiple Sclerosis Clinic. The department of neurology will provide neurological supervision and clinical evaluations for the referring physician. Research projects will be conducted by the department. Physical therapy and related treatments will be administered at the Rehabilitation Institute of Metropolitan Detroit and other community rehabilitation agencies.

MINNESOTA

Dedicate Hall Honoring Dr. Diehl.—Dr. Harold S. Diehl, dean emeritus of the University of Minnesota College of Medical Sciences, Minneapolis, was honored recently at a medical symposium and dedication of a new medical school building named Diehl Hall. The $2,750,000 building will be completed next fall and will house the university's medical-biological library and medical research facilities. Dr. Diehl is now residing in New York City, where he is senior vice-president for research and medical affairs and deputy executive vice-president of the American Cancer Society.

Report on Decrease in Syphilis.—*Minnesota's Health*, a publication of the Minnesota Department of Health, has reported that four decades ago, venereal disease was a serious problem in Minnesota. Since then, congenital, neural, and infectious syphilis have been virtually eliminated and the number of reported resident cases of syphilis of all types cut from a peak of 4,300 and a morbidity rate of 173.3 per 100,000 population in 1925 to a record low of 137 reported cases and a provisional morbidity rate of 4.0 per 100,000 in 1958. In the first quarter of the latter year, the state's rate was 5.3, a figure lower than in 45 other states, according to U. S. Public Health Service statistics. Had the 1925 rates continued unabated, the state would have had an estimated 5,830 resident cases of syphilis in 1958, a figure more than 40 times the actual number. Most cases of the disease are now discovered and treated in time to prevent late active, cardiovascular, neural, and congenital syphilis. The "failure rate" (late active and congenital syphilis per 100,000 population) dropped from 32.0 in 1940 to 3.5 in 1952, the last year for which such statistics are available. Only 20 infectious cases were reported during 1958, and the state reportedly was the first in the nation to go through an entire year(1950) without a newborn luetic birth. An occasional congenital case involving older persons still appears, however. Sixty cases were reported in 1946, only four in 1958. Since 1953, there have been no reported resident cases involving the newborn. Deaths with syphilis as a major or contributory cause have been four to five times lower than rates of 25 years ago. During 1957, deaths in which syphilis was the major cause totaled 39.

NEBRASKA

Annual Session in Omaha.—The 91st annual session of the Nebraska State Medical Association will be held April 27-30, at the Hotel Paxton, Omaha, according to Dr. Fay Smith, Imperial, president of the association. Activities include scientific programs, meetings of the governing bodies, and "Sportsman's Day." The meeting will be officially opened April 28 with the presidential address, followed by the installation of the incoming president for 1959-1960, Dr. Ezra E. Koebbe, Columbus. Highlight of the meeting will be the annual banquet at which 29 physicians who have practiced medicine for 50 years will be honored guests and receive 50-year pins in recognition of their service to medicine. Principal speaker for the evening will be Dr. Russell B. Roth, Erie, Pa., who will discuss "A Humorous View of Medical Public Relations." "This meeting will provide all the necessary qualities to give the attending physician a concise and informative program of the latest progress in medicine," Dr. Smith said. Holding their 34th annual meeting will be the Woman's Auxiliary. For information write the Nebraska State Medical Association, 1315 Sharp Building, Lincoln, Neb.

NEW YORK

Chilean Visitor.—Dr. Rafael Darricarrete, director of the School of Medicine of the University of Concepcion in Chile is visiting the New York State University Upstate Medical Center, Syracuse, under a fellowship of the World Health Organization. Dr. Darricarrete is studying the organization of medical education in the United States. He was awarded the WHO fellowship to study plans and methods of teaching in medical schools, curriculum structure, group organization, school organization, and selection of students. Dr. Darricarrete is a professor of bacteriology at the University of Concepcion, and former head of the B. C. G. department, Bacteriological Institute of Concepcion.

New York City

Annual Lecture Given by Dr. Harvey.—The seventh annual Emanuel B. Schoenbach Memorial Lecture was delivered in the Solarium, Kronish Pavilion, Maimonides Hospital of Brooklyn, April 16 by Dr. A. McGehee Harvey, professor of medicine, Johns Hopkins University School of Medicine and physician in chief, Johns Hopkins Hospital, Baltimore. Dr. Harvey's talk was on "Systemic Lupus Erythematosus."

OHIO

Sir Francis Walshe Visits Cincinnati.—On April 25 Sir Francis Walshe, British neurologist who is visiting professor of neurology at the University of Cincinnati College of Medicine and Cincinnati General Hospital, April 17-26, presented a lecture at the Veterans Administration Hospital Auditorium on "Mind and Brain." Sir Francis came to the United States through the joint efforts of the University of Cincinnati, Washington University, St. Louis, and the

University of California, San Francisco. At Cincinnati he conducted conferences, ward rounds, and a neurological clinical pathological conference.

Plan Kettering Memorial Medical Center.—Mr. Eugene W. Kettering, son of the late Charles F. Kettering, inventor, has announced plans to develop a 4-million-dollar medical center, including a 200-bed hospital, medical research building, health museum, and quarters for the Montgomery County Medical Society. The Kettering Memorial Medical Center would be situated on the 90-acre Kettering estate located in Kettering Village adjacent to Dayton and would include all of the estate except the residence and immediate grounds which the family will continue to occupy. Financing will be by friends and associates of the late Mr. Kettering, who have indicated their wish to join in developing the medical center, Mr. Kettering said. The project will take two years to complete after contracts are awarded. The hospital is designed for future expansion to 400 beds. Mr. Kettering, who resides in Hinsdale, Ill., has given a health museum to that community. He said the museum planned for the memorial center would be a facility for public education. The building would also house the Montgomery County Medical Center. The new hospital will be privately administered, and will be operated on the open staff principle whereby any physician may practice there so long as he meets the necessary professional standards. Development of the project is to be under direction of the Montgomery County Foundation for Research and Education, with Mr. Kettering as foundation chairman. Physician members of the foundation include Drs. G. Douglas Talbott, Dayton, and Col. John P. Stapp, Aero Medical Laboratory, Wright Air Development Center.

PENNSYLVANIA

General Practice Meeting in Bedford.—The 11th annual scientific assembly of the Pennsylvania Academy of General Practice will be held April 29-May 2 at the Bedford Springs Hotel, Bedford. Sessions are planned under the following headings:

The Management of Automotive Injuries.
Cardiology.
Ophthalmology.
Office Diagnosis, Therapeutics and Pharmacology.
Trauma.

A Symposium on Pediatrics May 2 will include papers by Dr. Edward Press and Dr. Mary Allen Engle, New York City, Dr. Paul Gyorgy, Philadelphia, and Dr. John Lester Reichert, Chicago. Exhibits are planned and question-and-answer periods will conclude three of the sessions. Ten hours of category I credit by the American Academy of General Practice will be given for attendance. For information write the Pennsylvania Academy of General Practice, 4450 State Road, Drexel Hill, Pa.

SOUTH DAKOTA

Dr. Parke Honored.—Dr. Leroy L. Parke, general practitioner in Canton for 46 years, was named "Man of the Year" by the Canton Chamber of Commerce at its annual banquet at the Masonic Temple Jan. 8. Dr. Parke received a lapel pin proclaiming him as "1958 Man of the Year." He has been mayor of the town, a member of the City Council, and served a number of terms as Republican County Chairman.

Plan Fall Meeting for Hunters.—The Council of the South Dakota State Medical Association has voted to continue its "Fall Hunters' Medical Meeting" in 1959, which combines a medical program with pheasant hunting. Lectures are given each morning and evening with hunting in the afternoon. The meeting is usually held the first five days of the hunting season. Physicians from any part of the country are welcome to attend. Enrollment is limited and applications are handled on a "first come, first served" basis. For information, write Mr. John C. Foster, Executive Secretary, South Dakota State Medical Association, 300 First National Bank Building, Sioux Falls, S. D

WASHINGTON

Swedish Surgeon Named Walker-Ames Professor.—Dr. John Philip Sandblom, president of the University of Lund, Sweden, has been appointed a Walker-Ames Professor of Surgery at the University of Washington School of Medicine, Seattle, for a period of six weeks, during March and April, 1960. Dr. Sandblom, is an honorary fellow of the American College of Surgeons, and is immediate past-president of the Swedish Surgical Society. He is founder of the International Surgical Club, and is the author of more than 70 research papers on surgical subjects. While at the university, Dr. Sandblom will lecture to medical students and residents and will give research seminars and demonstration operations.

GENERAL

Neurological Surgeons Meeting in New York City.—The 50th meeting of the Society of Neurological Surgeons will be held at the Neurological Institute of New York, New York City, April 27-28, under the presidency of Dr. Leonard T. Furlow, St. Louis, who will present "The Neurosurgical Aspects of Neurilemommas of the Seventh Cranial Nerve" the morning of April 28. The institute is celebrating its 50th anniversary. Fourteen papers are scheduled for presentation, including "Neutron Capture Therapy—Promise or Fantasy," by Dr. Lee E. Farr, medical director, Brookhaven National Laboratory, Associated Universities, Inc., Upton, Long Island. An exhibit of early New York neurosurgical contributions has been arranged by Dr. Byron Stookey, Sharon, Conn. Discussions and a ladies' program are planned, and the annual dinner will be held April 27, 7 p. m., at the Waldorf-Astoria. For information write Dr. Bronson S. Ray, 525 E. 68th St., New York 21.

Committee for Information on Alaska.—An Interagency Research Advisory Committee was formed by representatives of the Alaska Department of Health, Alaska Native Health Service (U. S. Public Health Service), Arctic Aeromedical Laboratory (U. S. Air Force), and Arctic Health Research Center (U. S. Public Health Service) for the purpose of assisting scientific investigators in medical and allied fields who may wish to perform research in Alaska. The committee is prepared to assist investigators sponsored by a recognized institution by explaining local situations, in meeting logistic difficulties, and in making available Alaskan facilities. Persons desiring such assistance should write Mr. E. M. Scott, Chairman, Interagency Research Advisory Committee, Arctic Health Research Center, Box 960, Anchorage, Alaska.

Meeting on Goiter in Chicago.—The American Goiter Association will meet at the Drake Hotel, Chicago, April 30-May 2. Over 30 papers are scheduled for presentation including "The Occurrrence of Iodinated Tyrosines in Human Plasma," by Helen E. A. Farran, B.Sc., and R. Bird, Ph.D., London, England, and "Observations Concerning the Free Myo-Inositol of Thyroid Tissue," by Dr. Norbert Freinkel, Dr. Sidney H. Ingbar, Dr. Charles J. Goodner, and Mr. Robert W. White, Boston, and Rex M. C. Dawson, Ph.D., Babraham, Cambridge, England. The presidential address will be given May 1, 2 p. m., by Dr. Warren H. Cole, Chicago, to be followed by the Van Meter prize essay and a round-table discussion, "Thyroid Carcinoma: Morphologic Types and Their Biologic Behavior," moderated by Dr. Lewis B. Woolner, Rochester, Minn. For information write Dr. John C. McClintock, 149½ Washington Ave., Albany 10, N. Y., Secretary.

National Convention on Tuberculosis.—The 1959 annual meetings of the National Tuberculosis Association, the American Trudeau Society, and the National Conference of Tuberculosis Workers will be held at the Palmer House, Chicago, May 24-29. An organizational meeting of the Governing Council of the NCTW is planned. Medical, public health, and nursing sessions will begin May 19, and general sessions will include an opening keynote program that morning. The American Trudeau Society committee and council meetings will be held May 22-24. The Trudeau sessions will include two symposiums: "Pulmonary Emphysema" and "Smoke, Smoking, and Chest Diseases," moderated by Drs. Richard V. Ebert, Little Rock, Ark., and Norton Nelson, New York City, respectively. The Amberson Lecture, "Viral Infections in Man: Problems and Progress," will be given by Dr. Frank L. Horsfall Jr., New York City, and the Robert Keeton Memorial Lecture, "Chronic Bronchitis: Clinical Characteristics, Pathogenesis, and Pathology," will be given by Dr. Charles M. Fletcher, London, England. Case conferences and demonstrations are planned. For information write the National Tuberculosis Association, 1790 Broadway, New York 19.

Surgeons Plan Midsummer Tour.—The International College of Surgeons will conduct a midsummer postgraduate tour, and Dr. Ross T. McIntire, executive director, will be the coordinator. Countries to be visited are the Netherlands, Denmark, Norway, Sweden, Finland, Russia, Austria, Germany, and France. Departures will be from New York July 17 on the S. S. Nieuw Amsterdam or by plane July 24. Tour participants will take in the Amsterdam meeting of the college, July 25-26, and the Helsinki meeting, Aug. 8-9; spend three days in Leningrad, Aug. 11-13, and three days in Moscow, Aug. 15-17; and meet with the fellows of the I. C. S. in Vienna, Aug. 19-20. Plane passengers will return to New York Aug. 27 and boat passengers will arrive Sept. 2. For information, write to Dr. Ross T. McIntire, executive director, International College of Surgeons, 1516 Lake Shore Drive, Chicago 10.

Meeting on College Health in Philadelphia.—The American College Health Association will hold its 37th annual meeting at the Warwick Hotel in Philadelphia May 6-9. The speaker at the association banquet, May 7, will be Dr. Richard A. Kern, Philadelphia, emeritus professor of medicine, Temple University School of Medicine, rear admiral, M. C., U. S. N. R., retired, and former president of the American College of Physicians. Dr. Donald A. Dukelow, Chicago, will address delegates during the opening general session May 6. The organization comprises some 300 colleges and universities throughout the United States and Canada, and there are about 500 individual members, most of whom are physicians and nurses engaged in student medicine at the college level. For information, write: Dr. Bruce S. Roxby, Chairman, Committee on Local Arrangements, Temple University Health Service, Broad Street at Montgomery Avenue, Philadelphia 22.

Student Meeting in Chicago.—Scientific papers will be presented by medical students and residents for the first time at the ninth annual convention of the Student American Medical Association April 30-May 3 at the Sheraton Hotel, Chicago. The papers will deal with such medical topics as cancer, hormones, internal parasites, and blood cholesterol levels. Eight medical students and three residents will present their papers at scientific sessions May 1 and 2. Featured speakers will be Dr. Alton E. Ochsner, New Orleans, who will discuss smoking and its relationship to lung cancer at the Saturday session, and Dr. Corbett H. Thigpen, Augusta, Ga., psychiatrist, who wrote "The Three Faces of Eve." Eight scientific exhibits, prepared by students, and four prepared by interns and residents, will be on view during the meeting. The House of Delegates will meet on April 30 and May 3. The Woman's Auxiliary to SAMA will hold its second annual meeting simultaneously. The annual banquet and dance May 1 will feature Carl C. Byers, Cleveland, speaking on "He Who Laughs—Lasts!" The choir from the Wayne State University College of Medicine, Detroit, will sing. A new feature of the meeting will be a photographic salon, which will show pictures of both medical and general interest. For information, write the Student American Medical Association, 430 N. Michigan Ave., Chicago 11.

Meeting on Cleft Palate Rehabilitation.—The 17th annual meeting of the American Association for Cleft Palate Rehabilitation will be held April 30-May 2 at the Sheraton Hotel, Philadelphia, under the presidency of Jack Matthews, Ph.D., Pittsburgh. April 30 will be devoted to a short course on problems associated with rehabilitation of individuals with cleft lips and palates and will include round-table discussions. The general sessions will include the following papers by foreign authors:

Cephalometric Measurements on Adult Patients with Unoperated Cleft Palates, Drs. Fernando Monasterio and Alfonso Serrano Rebeil, Mexico, D.F., Mexico.
Cleft Lip and Palate in Twins and Offspring of Twins, Elizabeth Curtis, M.A., Toronto, Canada.
Speech Analysis of Over 20 Children, Prior and Following Pharyngeal Flap Type Repair, Margaret Hamlen, L.C.S.T., Toronto, Canada.

The annual business meeting is planned for 3:30 p. m., May 1. Fee for nonmembers is $3. For information, write D. C. Spriestersbach, Ph.D., Department of Otolaryngology, University Hospitals, Iowa City, Iowa, Secretary-Treasurer.

Training Program in Steroid Biochemistry.—The Worcester Foundation for Experimental Biology, Shrewsbury, Mass., with the department of chemistry, Clark University, Worcester, Mass., and the department of biochemistry, College of Medicine, University of Utah, Salt Lake City, announced the 1959-1960 session of the Training Program for Steroid Biochemistry. "To alleviate the shortage of qualified trained personnel in steroid research," a program will be sponsored by the U. S. Public Health Service through the National Cancer Institute, National Institutes of Health. The courses will stress both theoretical and practical aspects as well as specialized laboratory techniques in steroid research. Postdoctoral candidates (M.D. or Ph.D.) selected for admission both at Worcester and Utah will receive stipends of $5,500 for one year. Predoctoral candidates (B.S., M.S., or equivalent) selected for admission (only at Worcester) will receive stipends of $1,800 for a six-month period. Send inquiries and requests for applications to: Dr. Kristen Eik-Nes, Department of Biochemistry, College of Medicine, University of Utah, Salt Lake City. Classes start Oct. 1. Final date for completion of application is June 1.

Meeting of Pediatricians.—The 69th annual meeting of the American Pediatric Society will be held May 6-8 at The Inn, Buck Hill Falls, Pa., under the presidency of Dr. Joseph Stokes Jr., who will present the presidential address May 6, 8 p. m. Guest speaker at the first session will be Dr. George Siim, State Serum Institute, Copenhagen, Denmark, will present "Studies on Acquired Toxoplasmosis." Of the 97 papers scheduled for presentation the following include foreign authors:

Relation of Intracellular Ions to Metabolite Sequences in Kwashiorkor, Drs. Jack Metcalf, Chicago, Silvestre Frenk, Mexico, D.F., Mexico, and Irena Antonowicz, M.S., Boston.
Motions of the Pharynx and Larynx with Aeration of the Lung at Birth, Drs. James F. Bosma, Salt Lake City, Utah, and John Link, Stockholm, Sweden.
Familial Pulmonary Fibrosis and Its Relationship with the Hamman-Rich Syndrome, Drs. Bernard Laski, W. L. Donohue, J. D. Munn, and Irene Uchida, Ph.D., Toronto, Canada.

A business meeting is planned for May 7, 8:30 p. m. For information write Dr. Aims C. McGuinness, Secretary-Treasurer, American Pediatric Society, 2800 Quebec St., N. W., Washington 8, D. C.

Dr. Boggs to Direct Fund for Education.—Dr. Robert Boggs was appointed director of the Basic Medical Research Program by the National Fund for Medical Education. The Medical Research Program, recently organized by the national fund, will administer funds raised by local United Funds and Community Chests, affiliated with the United Community Funds and Councils of America, for support of fundamental basic research on a national scale. The fund reportedly will not compete with the national voluntary health agencies which sponsor large numbers of research projects in specific fields, "but rather will complement the basic research activities which are a part of these programs by initiating research principally in areas that are not ordinarily covered by specific research projects." Dr. Boggs is a former dean of the New York University Post Graduate Medical School where he served from 1948 to 1955. He is chairman of the National Committee for Resettlement of Foreign Physicians and a consultant on medical projects of the Unitarian Service Committee. In 1959, the National Fund for Medical Education will award grants of over 3 million dollars to the medical schools, bringing to nearly 19 million dollars the total awarded since 1951, when the first grants were made.

Grants to Aid School Faculties.—Twenty-five physicians, teachers, and research workers on the faculties of medical schools in the United States and Canada were appointed Markle Scholars in Medical Science by the John and Mary R. Markle Foundation, New York. Each appointment carries with it a $30,000 grant, appropriated to the medical school where the scholar will teach and do research, to be used toward his support and to aid his research. In the 12 years the fund has been making the scholar grants, over 250 doctors in 74 medical schools in the U. S. and Canada have been aided with total appropriations of $7,550,000. The purpose of the program is "to strengthen medical education by offering academic security and financial help to teachers and investigators in medical schools early in their careers." There were more applicants for the grants this year than ever before. The 25 scholars were selected from nominees from 65 medical schools by five committees of educators and other professional men through extended interviews over three-day periods. The John and Mary R. Markle Foundation was established in 1927 by the late John Markle, Pennsylvania coal operator, "to promote the advancement and diffusion of knowledge . . . and the general good of mankind."

Awards for Heart Research.—The American Heart Association announced the award of $1,562,243 to 182 scientists engaged in a broad range of research studies, most of them in the category of basic research, aimed at pinpointing the underlying causes of heart and blood vessel disease. The awards, which went to individuals in 28 states, the District of Columbia, and two foreign countries, are for 12 months, beginning July 1. Dr. Francis L. Chamberlain, San Francisco, president of the association, pointed out that the awards were made possible through public contributions to the annual Heart Fund appeal. They represent the first part of the 1959-1960 national research support program in which the national office of the American Heart Association participates jointly with its state and local affiliates. A second group of awards, representing grants-in-aid, will be announced in the near future. The fellowship awards just announced include provision for the association's six "career investigators," scientists selected to receive support throughout their productive lives. Also named were 83 "established investigators." This category of award provides five years of uninterrupted support to mature scientists conducting independent programs of research. Ten established investigators also received supplementary grants to help underwrite the costs of technical assistance, equipment, and supplies required for their research. Also named were 45 scientists as "advanced research fellows" and 48 as "research fellows."

Conference on World Health.—The second National Conference on World Health will be held at the Statler Hotel in Washington, D. C., May 7-9, under the chairmanship of Dr. Milton S. Eisenhower, president of the Johns Hopkins University, Baltimore. Among those scheduled to speak is the President of the United States. Arthur S. Flemming, Secretary of Health, Education and Welfare and Dr. Leroy E. Burney, Surgeon General, U. S. Public Health Service, and leaders in public health, medicine, science, and industry will participate as speakers or discussion leaders. Dr. Abraham Horwitz, director, Pan American Sanitary Bureau, Regional Office of the World Health Organization, will speak. Special topics will be taken up in panel discussions and study groups which will report at the end of the conference: (1) prospects for an International Health Year; (2) health and economic development; (3) health and the American image abroad; (4) problems of health in relation to population changes; (5) training and exchange programs of public health personnel; (6) international health and medical research; and (7) the role of nongovernmental health organizations and individuals in the international promotion of public health. Any interested person may take part in the forum discussions and working parties of the conference. Registration will be May 7, 10 a. m.-2 p. m. The fee is $3. Students may register free. The conference is held under the sponsorship of the National Citizens Committee for the World Health Organization, which sponsored the first National Conference on World Health in Washington in 1953. For information, write Mr. Philip E. Nelbach, Executive Secretary, National Citizens Committee for the WHO, 1790 Broadway, New York 19, N. Y.

Society News.—Dr. Lester R. Dragstedt, professor of surgery, University of Chicago, was reelected president of the **National Society for Medical Research.** Also reelected were vice-president, Dr. Alfred Blalock, chief of surgery, Johns Hopkins University, Baltimore; and secretary-treasurer, Dr. Louis N. Katz, head of cardiovascular research, Michael Reese Hospital, Chicago.——The **Mississippi Valley Medical Society** elected the following officers for 1959: president-elect, Arkell M. Vaughn, Chicago; Illinois vice-president, Frank H. Fowler, Chicago; Iowa vice-president, William J. Wolf, West Union; Kansas vice-president, Clarence H. Benage, Pittsburg; Minnesota vice-president, Jacob A. Bargen, Rochester; Missouri vice-president, Barney W. Finkel, St. Louis; Nebraska vice-president, Clyde L. Kleager, Hastings; North Dakota vice-president, Reuben H. Waldschmidt, Bismarck; South Dakota vice-president, Alonzo P. Peeke, Volga; Wisconsin vice-president, Wallace S. Marshall, Watertown; secretary-treasurer, Harold Swanberg, Quincy, Ill.; assistant secretary-treasurer, Preston C. Hall, St. Louis; accounting officer, Jacob E. Reisch, Springfield, Ill. The 24th annual meeting will be held at the Hotel Chase, St. Louis, Sept. 29-Oct. 1, immediately preceding the American Medical Writers' Association meeting Oct. 2-3. The 1959 president is Dr. Arthur F. Fritchen, Decorah, Ia., trustee, Iowa State Medical Society, elected Nov., 1957.—Dr. Cecil M. Kohn, of Kansas City, Mo., was named president of the **American College of Allergists**, at the 15th annual congress of the college, succeeding Dr. Merle W. Moore of Portland, Ore. Named president-elect is Dr. Giles A. Koelsche, Rochester, Minn. Other officers include Dr. Philip M. Gottlieb, Philadelphia, first vice-president; Dr. William B. Steen, Tucson, Ariz., second vice-president; and Dr. Meryl M. Fenton, of Detroit, secretary.—The **Rocky Mountain Radiological Society** has elected the following officers: Drs. George A. Unfug, Pueblo, Colo., president; Gerald S. Maresh, Denver, president-elect; Peter E. Russo, Oklahoma City, Okla., first vice-president; Paul E. Re Pass, Denver, second vice-president; John H. Freed, 4200 E. Ninth Ave., Denver 20, secretary-treasurer; and H. Milton Berg, Bismarck, N. D., historian. The 1959 meeting will be held at the Shirley–Savoy Hotel, Denver, Aug. 20-22.

CANADA

Laurentian Hormone Conference.—The 1959 Laurentian Hormone Conference of the American Association for the Advancement of Science will be held at Mont Tremblant Lodge, Mont Tremblant, Quebec, Aug. 30-Sept. 4. Investigators interested in attending this conference should apply to the Committee on Arrangements, Laurentian Hormone Conference, 222 Maple Avenue, Shrewsbury, Mass. The conference is arranged under four general headings: Mechanism of Hormone Action, Peptide Hormones, Thyroid Hormones, and Hormones and Metabolism. Papers by foreign participants will include "Hormonal Activity of Active Polypeptides," by Hector Croxatto and Livio Barnafi, Catholic University, Santiago, Chile, and "Influence of Hormones on Adipose Tissue as a Center of Fat Transport," H. E. Wertheimer, The Hebrew University–Hadassah Medical School, Jerusalem, Israel. Applications will be screened and invitations issued by the Committee on Arrangements by June 12.

Establish Lectureship in Ophthalmology.—Dr. Walter W. Wright, University of Toronto professor emeritus of ophthalmology, has been honored by a lectureship in his name established with funds raised by department of ophthalmology staff members, former students, and friends. Dr. Wright conceived and developed the postgraduate training of physicians in eye diseases, reportedly the first such training in Canada, which began at the University of Toronto in 1941. Dr. Wright is also consultant to the Canadian National Institute for the Blind, the Toronto General Hospital, and the Hospital for Sick Children. He joined the University of Toronto staff in 1908, served as an ophthalmic specialist in the Canadian Army Medical Corps, returned to the university in 1921, and headed the department of ophthalmology from 1941 until retirement in 1946. The first Walter W. Wright lecture was given by Prof. Norman Ashton, ophthalmic pathologist of the Institute of Ophthalmology, London, England, who spoke on "A New Approach to the Problem of Diabetic Retinopathy" at the Academy of Medicine Feb. 27.

LATIN AMERICA

Cuba Joins Malaria Eradication Drive.—The new Cuban government and the Pan American Health Organization recently pledged themselves to eradicating malaria and the carrier of urban yellow fever in Cuba. The agreement was signed by provisional President Manuel Urrutia and Minister of Health Dr. Julio Martinez Paez for Cuba and Dr. Abraham Horwitz, of Chile, director of the Pan American Sanitary Bureau, regional office for the Americas of the World Health Organization and PAHO's operating arm, for the international health organization. Cuba has supported the resolutions in favor of the hemisphere and global malaria eradication campaigns in Pan American Sanitary Conferences and World Health Assemblies, but only now has it been possible to start on an eradication program. Though begun in 1953, Cuba's efforts toward eradicating the Aëdes aegypti mosquito have been modest, reportedly because of lack of funds. Under the terms of the new agreement they will be expanded.

FOREIGN

Symposium on Sulfur.—The Third International Symposium on Sulfur Therapy will be held in Tabiano and in Salsomaggiore, Italy, May 8-10 on occasion of the inauguration of the new termae of Tabiano "Emilio Respighi." Professors Demenico Campanacci, of the University of Bologna, and Carlo Bianchi, of the University of Parma, will preside. Italian and foreign scientists will participate and will read papers, including Dr. Piero P. Foa, of Chicago, and speakers from Austria, France, Hungary, and Spain. For information, write: Segreteria,

Third International Symposium on Sulfur Therapy, Institute di Patologia Medica, Ospedale Sant'Orsola, Bologna, Italy.

Seminar of Ophthalmology in Tunis.—The first North African Seminar of Ophthalmology will be held in Tunis on May 3-6. The Societe Tunisienne d'Ophthalmologie will meet on the occasion of its third anniversary, and the opening of the Ophthalmological Center will be a part of the seminar, at which Algerian and Moroccan Colleagues, will participate. The subjects will be the following: trachoma; keratoplasty; and recent advances in ophthalmology. Free communications (on internal medicine, ophthalmology, avitaminosis), film projections, and operating sessions will be included. French, English, and Arabic will be accepted for the discussions. Excursions of one or three days will be organized at the end of the meeting. A special program will be prepared for ladies. For information, write Societe Tunisienne d'Ophthalmologie, Le Secretaire General, Dr. R. Mabrouk, Centre Ophthalmologique, Tunis.

CORRECTION

New Mexico Meeting in Las Cruces.—In The Journal, March 28, page 1490, in the Medical News section, sessions for the annual meeting of the New Mexico Medical Society, May 6-7, were listed as being held at New Mexico State University, Albuquerque. This should have read Milton Hall at New Mexico State University, Las Cruces.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications is July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral.* For candidates on the West Coast, Portland, Ore., Sept. 9-12. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date far filing application was March 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *I. Oral and Clinical.* Chicago, May 8-19. Formal notice of the exact time of each candidate's examination will be sent him in advance of the examination dates. Candidates who participated in the Part I examinations will be notified of their eligibility for the Part II examinations as soon as possible. Deadline for receipt of new and reopened application for the 1960 examinations is Aug. 1, 1959. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Oral.* Philadelphia, June 2-6; St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 19-21, 1960. The deadline for the receipt of application is Aug. 15, 1959. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application is April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pediatrics: *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application was February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application is March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: New Orleans, Mar. 16-17; Chicago, Oct. 19-20; New York, Dec. 14-15. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Examination.* Chicago, June 2-4. If needed a special examination will be offered at this time in Nuclear Medicine to diplomates in Radiology or Therapeutic Radiology. The deadline for filing applications is April 1. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. *Part II.* Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 1959. Final date for filing application is July 1. *Oral.* September. Final date for filing application is July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. Final date for filing application is Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

GOVERNMENT SERVICES

NAVY

Symposium on Nuclear Medicine.—The United States Naval Medical School, National Naval Medical Center will present its second symposium on advances in nuclear medicine on May 9. This symposium will cover all aspects of the management of the acute radiation syndrome and the care of radiation casualties. The morning session will be devoted to a discussion of low background total body counting, while the afternoon session will cover the diagnosis, management, and treatment of acute radiation syndrome. Authorities scheduled to appear for this symposium are Dr. C. E. Miller, Argonne National Laboratory; Dr. Frederick Reines, Los Alamos Scientific Laboratory; Dr. M. A. Van Dilla, Los Alamos Scientific Laboratory; Dr. R. C. McCall, General Electric Company; Commander H. J. Waters, Technical Assistant for Science Advisor, White House; Dr. Gordon Brownell, Massachusetts General Hospital; Dr. Eugene Cronkite, Brookhaven National Laboratory; Major Kent Woodward, MC, USA, Walter Reed Institute of Research; Dr. Gordon Zubrod, National Cancer Institute; Dr. H. D. Bruner, Division of Biology and Medicine, Atomic Energy Commission; Dr. F. P. Ellinger, U. S. Naval Medical Research Institute; Lieut. Col. Gerald McDonnell, Office of the Army Surgeon General; Dr. Gould A. Andrews, Oak Ridge Institute of Nuclear Studies; and Commander William McFarland, MC, USN, United States Naval Hospital.

There is no registration fee, and all those interested are invited to attend. A special luncheon program, at which Dr. Robert H. Hasterlik of the Argonne Cancer Research Hospital will speak, will be given at the Commissioned Officers' Club, National Naval Medical Center. For further information one may contact the Commanding Officer, U. S. Naval Medical School, National Naval Medical Center.

VETERANS ADMINISTRATION

Big Brother System.—A unique "big-brother" system is being used by hospitalized veterans in their fight against mental illness. Recovering patients at the VA mental hospital in Salisbury, N. C., have formed a society known as "The Helping Hand," in which each member holds himself responsible for more seriously ill patients. Dr. S. J. Muirhead, manager of the hospital, said the society has proved an effective form of help for both its members and nonmembers. Improved patients can help less fortunate patients towards recovery in ways that the hospital staff cannot, since patients ofttimes notice improvement in the condition of their companions and thus become aware that their own improvement is possible. The society's membership is restricted to patients approved by its own screening committee and elected by unanimous vote.

Personal.—Dr. Irvin J. Cohen was appointed assistant chief medical director for planning to succeed Dr. William W. Fellows, who retired in March. Dr. Cohen will direct the medical care program for VA's 171 hospitals, about 100 outpatient clinics, and 17 domiciliary homes. He has been a deputy director for planning since August, 1958.

PUBLIC HEALTH SERVICE

Traineeship in Neurology.—A special traineeship program, under the direction of the National Institute of Neurological Diseases and Blindness, was initiated about three years ago to increase the number of investigators competent to meet the complex problems presented by neurological and sensory disorders. Since its inception, 163 persons have received one to three years of training at 48 institutions in the United States and 16 institutions in seven foreign countries. To qualify for an award, the candidate should have an M.D., Ph.D., or other equivalent degree and at least three years of training or experience pertinent to the training for which he seeks support. The applicant must be a United States citizen or have filed a declaration of intent.

Awards generally are made for not less than nine months and not more than one year, but all awards are subject to renewal for periods up to five years. Stipends are determined individually in accordance with each applicant's qualifications and the financial support needed to obtain the training applied for. Such stipends may range from $6,500 to $17,500 a year. Traineeships frequently are used by basic scientists and clinicians to obtain prolonged and thorough training in highly specialized areas related to their previous experience. For instance, a pediatrician may wish to take specialized training in neurology, ophthalmology, or otolaryngology; and a pathologist, anatomist, or pharmacologist may wish to receive training in the neurological aspects of his discipline. Other candidates seek to increase competence and knowledge in a particular facet of a chosen field for a shorter period. For example, academic and medical faculty members in increasing numbers are using this program to broaden their research experience during sabbatical or other institutional leaves of absence. Requests for complete information about the special traineeship program and application forms should be addressed to Chief of Extramural Programs, National Institute of Neurological Diseases and Blindness, National Institutes of Health, Bethesda 14, Md.

DEATHS

Barbour, Fredric Leaworth Ⓜ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911; served on the faculty of his alma mater; associated with the Illinois Central Hospital, where he died Feb. 7, aged 74.

Blumenthal, Basil Ⓜ Washington, D. C.; Columbia University College of Physicians and Surgeons, New York City, 1934; specialist certified by the American Board of Internal Medicine; veteran of World War II; clinical assistant professor of medicine; Georgetown University School of Medicine; associated with the Washington General Hospital and the Georgetown University Hospital, where he died Dec. 6, aged 49.

Brown, Charles Arthur, Kansas City, Mo.; University Medical College of Kansas City, 1905; died in the University of Kansas Medical Center Jan. 11, aged 76.

Brown, Grover Cleveland Ⓜ Ste. Marie, Ill.; Barnes Medical College, St. Louis, 1905; member of the American Psychiatric Association; served as managing officer of the Jacksonville (Ill.) State Hospital; at one time district health superintendent for the state; died in St. Anthony Memorial Hospital, Effingham, Nov. 30, aged 73.

Buch, Samuel Montgomery Ⓜ New York City; University and Bellevue Hospital Medical College, New York City, 1905; past-president and charter member of the Bronx Gynecological and Obstetrical Society; consultant, Jewish Memorial Hospital; died Jan. 24, aged 76.

Burnham, Leon Ray Ⓜ Augusta, Maine; Tufts College Medical School, Boston, 1930; veteran of World War II; chief of physical medicine and rehabilitation at the Veterans Administration Center, Togus; died Jan. 21, aged 52.

Burns, Emmet Samuel, Beaver Falls, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1891; died in Ellwood City Jan. 27, aged 90.

Burrows, Byron L., Mount Pleasant, Tenn.; Meharry Medical College, Nashville, Tenn., 1915; died in the Hubbard Hospital, Nashville, Jan. 15, aged 70.

Burton, Robert Elmore, Kingston, Ga.; Eastern University School of Medicine, Baltimore, 1913; past-president of the Bartow County Medical Society; held the post of mayor; served as president of the Kingston Lions Club; died in the Floyd County Hospital, Rome, Jan. 17, aged 68.

Byars, Alfred Henry, Coronado, Calif.; Barnes Medical College, St. Louis, 1898; veteran of World War I; died Jan. 19, aged 86.

Caro, Alfred, Elmhurst, N. Y.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1910; died in the Physicians Hospital, Jackson Heights, Dec. 27, aged 73.

Cary, Raymond John Ⓜ Long Beach, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1912; veteran of World War I; associated with the Seaside Memorial Hospital, where he died Jan. 7, aged 73.

Chalmers, Duncan Macfarlane Ⓜ Long Beach, Calif.; Boston University School of Medicine, 1934; veteran of World War II; certified by the National Board of Medical Examiners; formerly associated with the Indian Service in Juneau, Alaska; died Jan. 10, aged 51.

Cloyd, John Archer, Upper Darby, Pa.; University College of Medicine, Richmond, 1912; for many years a medical officer in the U. S. Navy; served on the staffs of the Presbyterian Hospital in Philadelphia, Bryn Mawr (Pa.) Hospital, and the Delaware County Hospital in Drexel Hill, where he died Jan. 20, aged 68.

Cook, Albert Thomas, Zapata, Texas; Southern Methodist University Medical Department, Dallas, 1912; for many years city and county health officer for Laredo and Webb County; health officer of Zapata County; died in the Mercy Hospital, Laredo, Jan. 21, aged 68.

Cooley, Chester Lynn Ⓜ San Francisco; Stanford University School of Medicine, San Francisco, 1928; specialist certified by the American Board of Obstetrics and Gynecology; on the faculty of the Stanford University School of Medicine; associated with Stanford University Hospitals, St. Elizabeth's Infant Hospital, Children's Hospital, and the Mary's Help Hospital; on the editorial board of the *Western Journal of Surgery, Obstetrics and Gynecology;* died Jan. 22, aged 64.

Corbett, Joseph Horace, Jasper, Fla.; Atlanta College of Physicians and Surgeons, 1901; died Jan. 25, aged 80.

Ⓜ Indicates Member of the American Medical Association.

Counts, William L. Ⓜ Chillicothe, Ohio; Medical College of Ohio, Cincinnati, 1897; an honorary member of the Chillicothe General Hospital staff; died Jan. 12, aged 92.

Cox, J. Emit Ⓜ Fresno, Calif.; Central Medical College of St. Joseph, Mo., 1895; for 30 years member of the board of the Fresno County Tuberculosis Association; at one time practiced in Coalinga, where he was school physician in the Coalinga School District and city health officer; died Dec. 28, aged 93.

Crawford, Georgina Lily Urquhart Ⓜ East Orange, N. J.; University of Toronto Faculty of Medicine, Toronto, Ontario, Canada, 1905; on the medical staff of the New Jersey Bell Telephone Company and Essex County Girls' Vocational School in Newark; served on the staff of Orange Memorial Hospital, where she died Feb. 2, aged 76.

Creskoff, Adolph Jay Ⓜ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1934; associate professor of clinical medicine at his alma mater; chief of hematology section, Hospital of the University of Pennsylvania; consultant in hematology, Veterans Administration Hospital in Philadelphia; consultant in hematology at the Delaware County Hospital in Drexel Hill, Pa.; died Jan. 22, aged 50.

Darling, Herbert Henry Ⓜ San Rafael, Calif.; Harvard Medical School, Boston, 1925; veteran of World Wars I and II; served as chief of the medical section of the Veterans Administration regional office in San Francisco, where he was formerly on the staffs of St. Francis, Stanford, and Children's hospitals; died Jan. 23, aged 58.

Davies, Daniel Jenkin Ⓜ Cincinnati; Miami Medical College, Cincinnati, 1900; specialist certified by the American Board of Obstetrics and Gynecology; on the faculty of the University of Cincinnati College of Medicine; associated with Bethesda, Deaconess, and Good Samaritan hospitals; died in the Christ Hospital Jan. 27, aged 87.

De Ferari, George Joseph, Brooklyn; University and Bellevue Hospital Medical College, New York City, 1925; interned at St. Vincent's Hospital in New York City; associated with the Brooklyn Doctors Hospital; for many years associated with the Brooklyn Hospital; died Jan. 10, aged 60.

Dickson, Archibald John Ⓜ La Crescenta, Calif.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1903; formerly on the staff of the Willard Parker Hospital in New York City; died in the Alta Vista Hospital, Pasadena, Jan. 11, aged 80.

Dixon, William Harvey, Rocky Mount, N. C.; Jefferson Medical College of Philadelphia, 1919; served as medical examiner for the Royal Arcanum for 37 years; died in the Park View Hospital Jan. 23 aged 63.

Dodd, David Wallace Ⓜ Louisville, Ky.; University of Louisville (Ky.) School of Medicine, 1917; veteran of World Wars I and II; assistant chief medical officer for the Veterans Administration; at various times associated with Veterans Administration hospitals in Lexington, Murfreesboro, Tenn., and Nashville, Tenn.; died in the Norton Memorial Infirmary Jan. 15, aged 66.

Dudley, Will Kenney, Paris, Ky.; Kentucky University Medical Department, Louisville, 1904; died in St. Joseph Hospital, Lexington, Jan. 17, aged 80.

Elliott, Joseph Norman Ⓜ Bloomington, Ill.; Northwestern University Medical School, Chicago, 1921; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; associated with the Brokaw Hospital in Normal and the Mennonite Hospital; veteran of World War I; died Jan. 21, aged 64.

Elliot, Robert Edwin Ⓜ Van Nuys, Calif.; Loyola University School of Medicine, Chicago, 1932; on the staff of the Valley Hospital; died Jan. 17, aged 51.

Engelman, Bruno Simon Ⓜ Buffalo, N. Y.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1921; member of the American Academy of general practice; on the staff of the Millard Fillmore Hospital; served a residency at the State Institute for the Study of Malignant Diseases; died Jan. 10, aged 63.

Forsythe, William Alexander, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1917; also a graduate in pharmacy; on the staff of the Mercy-Douglass Hospital; died Jan. 19, aged 74.

Friedman, Harry Falk Ⓜ Miami Shores, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1912; specialist certified by the American Board of Radiology; veteran of World War I; served on the faculty of his alma mater; formerly practiced in Boston, where he was on the faculty of Tufts College Medical School, and was associated with the Boston Dispensary, Westboro (Mass.) State Hospital, Beth Israel Hospital, Massachusetts Memorial Hospital, and New England Hospital for Women and Children; died Jan. 23, aged 68.

Garst, Virgil Paul, Malad City, Idaho; St. Louis University School of Medicine, 1913; Oneida County examining physician for Selective Service inductees during World War II; formerly member of the school board; served on the staff of the Oneida County Hospital; died Jan. 13, aged 78.

Ghering, Harold Alfred Ⓜ Edinboro, Pa.; University of Pittsburgh School of Medicine, 1913; veteran of World War I; for many years physician for Edinboro State Teachers College; on the staffs of the Hamot and St. Vincent's hospitals in Erie; vice-president of the First National Bank; died in the Hamot Hospital, Erie, Jan. 25, aged 72.

Goodwin, Frank Perry Ⓜ Jamestown, N. Y.; Cornell University Medical College, New York City, 1906; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; veteran of World War I; past-president of the Chautauqua County Medical Society; member of the staffs of the Jamestown General and Woman's Christian Association hospitals; died Jan. 16, aged 76.

Gosnell, Thomas E. Ⓜ Louisville, Ky.; University of Louisville Medical Department, 1886; died Jan. 7, aged 99.

Graves, Stephen Monroe Ⓜ Clarksville, Ark.; (licensed in Arkansas in 1903); died Feb. 1, aged 88.

Greene, Garland Vestal, Mocksville, N. C.; North Carolina Medical College, Charlotte, 1916; veteran of World War I; served as county coroner; died Jan. 27, aged 68.

Gross, Leroy Calderwood Ⓜ Auburn, Maine; Tufts College Medical School, Boston, 1930; on the staffs of the St. Mary's General Hospital and the Central Maine General Hospital in Lewiston, where he died Jan. 23, aged 60.

Hancock, Virgil Kinney Ⓜ Seattle; Northwestern University Medical School, Chicago, 1919; veteran of World War I; died in the Swedish Hospital Jan. 13, aged 68.

Handelman, Milton S. Ⓜ Chicago; University of Illinois College of Medicine, Chicago, 1933; associated with Weiss Memorial and Mount Sinai hospitals; died in Hollywood, Fla., Feb. 5, aged 51.

Hane, Richard Lincoln Ⓜ Pacific Grove, Calif.; Ohio State University College of Medicine, Columbus, 1924; fellow of the American College of Surgeons; past-president of the Monterey County Medical Society and the Monterey Academy of Medicine; formerly practiced in Fort Wayne, Ind., serving as president of the Allen County Medical Society and as secretary of the Fort Wayne Medical Society; veteran of World War II; formerly held a fellowship at the Mayo Clinic in Rochester, Minn.; associated with the Peninsula Community Hospital in Carmel and the Monterey Hospital, where he died Jan. 25, aged 58.

Hanson, Adolph Melanchton Ⓜ Faribault, Minn.; born in St. Paul Sept. 11, 1888; Northwestern University Medical School, Chicago, 1911; member of the Central Society for Clinical Research; past-vice-president of the Minnesota State Medical Association, which in 1933 awarded him a gold medal in recognition of his isolation of the parathyroid hormone; in December, 1932, the U. S. Patent Office confirmed Dr. Hanson's claim to the discovery; Dr. Hanson made the Smithsonian Institution, Washington, D. C., the benefactor of all royalties for the furtherance of scientific research; in 1927 awarded the first prize for work on parathyroid gland by the Minnesota Society of Internal Medicine; in 1935 awarded the gold medal of the Southern Minnesota Medical Association for his exhibit at the state meeting; the following year named an associate in research of the Philadelphia Institute for Medical Research; veteran of World Wars I and II; on the staff of St. Lucas Hospital; inventor of dural separator and bone elevator used in brain surgery; for many years in charge of the Hanson Research Laboratory and donated its scientific equipment to the chemistry department of St. Olaf College in Northfield, July, 1942, to be perpetuated as a special laboratory for advanced students; in 1943 St. Olaf College conferred on him the honorary degree of doctor of science in recognition of his work on the isolation of the active principle of various hormones; author of "Practical Helps in the Study and Treatment of Head Injuries," 1925; also wrote a chapter, Management of Gunshot Wounds of the Head and Spine, in Volume XI, the Medical Department of the U. S. Army in the World War; contributor of numerous articles on parathyroid and thymus glands, head, spine, and superficial nerve surgery; died Jan. 15, aged 70.

Haworth, Edgar Sylvester Ⓜ Wichita, Kan.; Kansas City (Mo.) Hahnemann Medical College, 1907; died Jan. 9, aged 78.

Heaps, Carrie Erdman, Shamokin, Pa.; Woman's Medical College of Baltimore, 1907; died in the Shamokin State Hospital Jan. 5, aged 75.

Heine, William Howard Ⓜ Fremont, Neb.; University of Nebraska College of Medicine, Omaha, 1905; also a pharmacist; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; served during World War I; on the staff of the Dodge County Community Hospital; died Jan. 24, aged 81.

Hetrick, Llewellyn Evans, Hampton, Conn.; born in Lancaster, Pa., Dec. 11, 1875; Hahnemann Medical College and Hospital, Philadelphia, 1898; specialist certified by the American Board of Otolaryngology; life member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; member of the New York Academy of Medicine; formerly associated with the New York Medical College, Flower and Fifth Avenue Hospitals and the New York Polyclinic Medical School and Hospital in New

York City, where he served on the staffs of the Metropolitan and Flower and Fifth Avenue hospitals; veteran of World War I; following the war, was active for 22 years in the medical officers reserve corps, with the rank of colonel, and was retired in 1955, according to Army regulations; during World War II was active as examining physician in the Selective Service System; died in Colchester Jan. 20, aged 83.

Hilldrup, Don Guernsey Ⓜ Colonel, U. S. Army, retired, Indianapolis; born in Windfall, Ind., Nov. 9, 1887; Indiana University School of Medicine, Indianapolis, 1915; after serving an internship at the Indianapolis City Hospital, entered the medical corps of the U. S. Army in 1917 and served with both the American Expeditionary Forces and the Army of Occupation in Germany until 1920; later served at various Army posts; during World War II established military hospitals in Central Africa and later was surgeon of the Fifth and Sixth U. S. Army Service Commands; awarded the Legion of Merit; retired Aug. 31, 1948; at one time a member of the Army Medical Retirement Board in Washington, D. C.; served for three years as medical director of the Indianapolis American Red Cross Blood Bank; fellow of the American College of Surgeons; died in the Memorial Clinic of Indianapolis Jan. 28, aged 71.

Hine, Ulis Bryan Ⓜ Indianapolis; Indiana University School of Medicine, Indianapolis, 1925; served as Marion County deputy coroner and member of the medical staff of the Indianapolis Motor Speedway; associated with the Methodist and St. Francis hospitals, and the Community Hospital, where he died Jan. 26, aged 61.

Houloose, James Ⓜ Los Angeles; Rush Medical College, Chicago, 1920; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; veteran of World War II; for many years associated with the board of education of Long Beach; served with the Veterans Administration; died Jan. 11, aged 69.

Hubbard, Samuel Thatcher Sr. Ⓜ Hackensack, N. J.; University of Vermont College of Medicine, Burlington, 1907; specialist certified by the American Board of Ophthalmology; at one time secretary of the Bergen County Medical Society; on the staffs of the Holy Name Hospital in Teaneck and the Hackensack Hospital; died in the Veterans Administration Hospital, New York City, Dec. 23, aged 77.

Ives, Grace D. Ⓜ Great Barrington, Mass.; Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1897; died Nov. 21, aged 97.

James, Theodoric V., Columbus, Miss.; Meharry Medical College, Nashville, Tenn., 1899; died in the Doster Hospital Jan. 15, aged 86.

Jefferson, James J., Johnstown, Pa.; born in 1874; Jefferson Medical College of Philadelphia, 1904; past-president of the Cambria County Medical Society, which in July, 1955, honored him for 50 years spent in the medical profession; at that time also was presented a plaque from the Medical Society of the State of Pennsylvania commemorating his long service as a physician; fellow of the American College of Surgeons; formerly surgeon of the Johnstown Plant, Bethlehem Steel Company, and Johnstown Works, U. S. Steel Corporation; for many years on the staff of the Conemaugh Valley Memorial Hospital; where he died Jan. 23, aged 84.

Johnson, Arthur Waldren Ⓜ Hales Corners, Wis.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1914; served overseas with the Canadian Army during World War I; fellow of the American College of Surgeons; associated with the Columbia Hospital and the Milwaukee Hospital, where he died Jan. 23, aged 69.

Jones, Ralph Roy Ⓜ Winchester, Ill.; Barnes Medical College, St. Louis, 1905; served as president of the school board; associated with the Illini Community Hospital in Pittsfield; died Dec. 14, aged 84.

Kapnick, Israel Ⓜ Providence, R. I.; Harvard Medical School Boston, 1938; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; a cancer consultant to the state department of health; associated with the Charles V. Chapin Hospital, Miriam Hospital, and the Roger Williams General Hospital; died in the Rhode Island Hospital Jan. 3, aged 45.

Kelly Leo Joseph, Ⓜ Trenton, N. J.; Georgetown University School of Medicine, Washington, D. C., 1935; certified by the National Board of Medical Examiners; served an internship at the St. Francis Hospital in Trenton and Fitzgerald–Mercy Hospital in Darby, Pa.; veteran of World War II; associated with the Wills Eye Hospital and the Philadelphia General Hospital in Philadelphia; died in Yardley, Pa., Jan. 30, aged 50.

King, William Franklin Ⓜ Indianapolis; Ohio Medical University, Columbus, 1898; for many years state health commissioner and secretary of the state board of health, and head of the first division of adult hygiene and geriatrics; a member of the planning committee of President Hoover's White House Conference on Child Health and Protection; wrote the constitution for the National Association of Nursing Homes and last year received a plaque citing his service; past-president of the Indianapolis and state Exchange clubs; died in the Methodist Hospital Jan. 27, aged 84.

Kinnaird, Virgil Gibney Ⓜ Lancaster, Ky.; born in Lancaster Oct. 16, 1890; Jefferson Medical College of Philadelphia, 1913; served as councilor of the Seventh District of the Kentucky State Medical Association; member of the American Academy of General Practice; served overseas during World War I; honored by the Lancaster Junior Chamber of Commerce when he was designated as the "Outstanding Citizen of the Year"; past-president of the Garrard County Medical Society; past-president of the Lancaster Rotary Club; a director of the Centre College of Kentucky in Danville, where he served as a trustee for Kentucky School for the Deaf; served as chief of staff of the Garrard County Memorial Hospital; associated with the Ephraim McDowell Memorial Hospital in Danville; died Jan. 11, aged 68.

Kline, Samuel Ⓜ Sioux City, Iowa; Sioux City College of Medicine, 1908; served on the faculty of his alma mater; associated with the St. Joseph Mercy, St. Vincent's and Lutheran hospitals; died Jan. 22, aged 76.

Knight, Robert, Seneca Falls, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1902; veteran of World War I; health officer for the town of Seneca Falls and outlying districts, a position which he held for more than 30 years; formerly associated with the New York State Department of Health in Albany; on the staff of the Seneca Falls Hospital; died in Clifton Springs Jan. 12, aged 79.

Lamar, Richard Vanderhorst, Marietta, Ga.; University of Georgia Medical Department, Augusta, 1902; at one time on the faculty of his alma mater; formerly associated with the Rockefeller Institute in New York City; served on the staff of the Milledgeville (Ga.) State Hospital; died Jan. 22, aged 75.

Lawler, Edmund Griffin Ⓜ Chicago; Loyola University School of Medicine, Chicago, 1925; assistant clinical professor of pediatrics at his alma mater; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; chairman of the department of pediatrics at the Little Company of Mary Hospital, where he died Jan. 23, aged 59.

Lawrance, Jackson Stuart Ⓜ Reading, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1905; fellow of the American College of Surgeons; in January, 1956, was honored by the Berks County Medical Society for 50 years of practice and was given a plaque; veteran of World War I and was awarded the Distinguished Service Cross; served on the staff of St. Mary's Hospital in Philadelphia; associated with St. Joseph's Hospital, where he died Feb. 6, aged 78.

Leader, Pauline Marie, Lancaster, Wis.; State University of Iowa College of Medicine, Iowa City, 1894; for many years associated with the Clarinda (Iowa) State Hospital; died Feb. 7, aged 101.

Leet, H. Halbert Ⓜ Lexington, Ky.; born in Lexington March 5, 1911; University of Louisville School of Medicine, 1937; specialist certified by the American Board of Psychiatry and Neurology; member of the American Academy of Neurology and the American Psychiatric Association; veteran of World War II; assistant professor of industrial medicine at the University of Cincinnati College of Medicine; instructor of neuropsychiatry at the State University of Iowa College of Medicine in Iowa City from 1939 to 1941; assistant professor of psychiatry at the Graduate School of Social Work, University of Kentucky, 1941-1942; lecturer of neuropsychiatry and psychosomatic medicine, Graduate School of Social Work, Tulane University in New Orleans from 1943 to 1946; associated with St. Joseph, Good Samaritan, Central Baptist, and Our Lady of the Oaks hospitals; died Jan. 26, aged 47.

Leymeister, Martin L. Ⓜ Reading, Pa.; Jefferson Medical College of Philadelphia, 1935; interned at the Wilkes-Barre (Pa.) General Hospital; member of the American Academy of General Practice; past-president of the Berks County Medical Society; served in the medical reserve corps of the U. S. Army from July 1, 1953, to July 31, 1955; associated with the Community General Hospital, where he died Jan. 25, aged 49.

Lieberman, Louis Manuel Ⓜ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1930; veteran of World War II; associated with the Hospital of the University of Pennsylvania; died in Merion Station, Pa., Jan. 19, aged 54.

Linton, Charles Damon Ⓜ Walkerton, Ind.; Indiana University School of Medicine, Indianapolis, 1929; associated with the Holy Family Hospital, La Porte; died Dec. 30, aged 54.

Littlefield, Jesse Braxton Ⓜ Tucson, Ariz.; University of Texas School of Medicine, Galveston, 1922; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; veteran of World Wars I and II; on the staffs of St. Mary's Hospital, Pima County General Hospital, and the Tucson Medical Center; consultant, Southern Pacific and Veterans Administration hospitals, and the U. S. Air Force Station Hospital, Davis-Monthan Air Force Base; died Jan. 12, aged 60.

Lockman, William L., Dallas, Texas; Memphis (Tenn.) Hospital Medical College, 1909; served with the Indian Service; died Jan. 10, aged 79.

Lyon, Edward George Ⓜ Dallas, Texas; Memphis (Tenn.) Hospital Medical College, 1911; served as full-time assistant health officer of the city of Dallas; died in the Veterans Administration Hospital Jan. 4, aged 74.

McAdams, Peter Stevens Ⓜ Cambridge, Mass.; Harvard Medical School, Boston, 1899; associated with the St. Elizabeth's Hospital in Boston, where he died Jan. 23, aged 86.

McCracken, Arthur James Ⓜ Bellefontaine, Ohio; Medical College of Indiana, Indianapolis, 1901; veteran of World War I; for many years city health commissioner and county coroner; died in the Monmouth (Ill.) Hospital Jan. 31, aged 85.

Marcy, Charles Howard Ⓜ Allison Park, Pa.; born in Cambridge Springs March 16, 1889; University of Pittsburgh School of Medicine, 1914; specialist certified by the American Board of Internal Medicine; member of the American College of Chest Physicians, American Trudeau Society, and the American Clinical and Climatological Association; fellow of the American College of Physicians, of which he was ex-governor; clinical professor of medicine at his alma mater; lecturer, University of Pittsburgh Graduate School of Public Health; past-president and secretary of the Pennsylvania Tuberculosis Society; medical director of the Tuberculosis League of Pittsburgh; veteran of World War I; member of the consultant staff, Presbyterian and Woman's hospitals, and Pittsburgh Diagnostic Clinic; member of the senior staff, Columbia Hospital in Wilkinsburg and St. Francis Hospital; area consultant in tuberculosis of the Veterans Administration; medical adviser, Industrial Hygiene Foundation; died in the Allegheny General Hospital, Pittsburgh, Jan. 18, aged 69.

Martin, Dwight Clifford, Summit, N. J.; Harvard Medical School, Boston, 1903; formerly chief of the bureau of tuberculosis, New York City Health Department; served on the faculty of Fordham University School of Medicine in New York City; formerly on the staffs of the Municipal Sanatorium of the Department of Health, Otisville, Seton Hospital, where he was president of the medical board, Bellevue, Presbyterian, and Knickerbocker hospitals; died Feb. 4, aged 80.

Martin, Hallie Eugene, La Fayette, Ky.; St. Louis College of Physicians and Surgeons, 1918; died in Hopkinsville Jan. 18, aged 73.

Masters, Howard Russell Ⓜ Richmond, Va.; born in Fredericksburg, July 2, 1894; Medical College of Virginia, Richmond, 1919; associate professor of clinical psychiatry and neurology at the Medical College of Virginia, where he joined the faculty in 1919; lecturer of abnormal and normal psychology at the College of William and Mary, Richmond division, from 1927 to 1929 and lecturer in psychiatry from 1927 to 1932; specialist certified by the American Board of Psychiatry and Neurology; past-president of the Tri-State Medical Association of the Carolinas and Virginia Neuropsychiatric Association, and the Mental Hygiene Society of Virginia, which he helped organize; member of the Endocrine Society, Richmond Academy of Medicine, and the American Psychiatric Association; a member of the Kappa Sigma, Omicron Delta Kappa, and Phi Chi fraternities; since 1926 member of the governor's advisory board on mental hygiene, Richmond; veteran of World War I; past-president and vice-president of the Memorial Guidance Clinic, and a member of its board since 1933; in 1953 appointed to the college of electors for the Hall of Fame of Great Americans; psychiatrist for the Virginia State Penitentiary from 1927 to 1930; associated with the Tucker Hospital, where he was president, Johnston–Willis, Sheltering Arms and Crippled Children's hospitals, and the Medical College of Virginia, Hospital Division; past-president of the Randolph–Macon Alumni Association; in 1956 the Randolph–Macon College awarded him an honorary L.L.D. degree; died Jan. 27, aged 64.

Meyerding, Edward August Ⓜ St. Paul; born in St. Paul Dec. 25, 1879; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; served as director of the division of hygiene and special classes of the public schools of St. Paul for fifteen years; for many years an executive secretary of the Minnesota Public Health Association and secretary of the Minnesota State Medical Association; on June 30, 1938, at the annual banquet of the state association, was presented with the society's first Distinguished Service Award created by its house of delegates, to be presented on occasion in recognition of special service to the association; past-president of the Mississippi Valley Conference on Tuberculosis; member of the House of Delegates of the American Medical Association from 1935 to 1936 and in 1939; in 1956 received the William G. Anderson Service Award of the American Association for Health, Physical Education and Recreation for his work with Minnesota school children; served during World War I and later was promoted to the rank of colonel in the reserve; organizer of the Minnesota Trudeau Society; member of the American College of Chest Physicians and the American Trudeau Society; died in St. Luke's Hospital Jan. 23, aged 79.

Mikolanda, Otto, Lorain, Ohio; University of Wooster Medical Department, Cleveland, 1903; for many years police surgeon; veteran of World War I; died in Millersburg Jan. 5, aged 78.

FOREIGN LETTERS

AUSTRIA

New Uses for Iproniazid.—At the meeting of the Society of Physicians in Vienna on Jan. 23, Dr. A. Pletscher stated that iproniazid inhibits the enzyme, monoamino oxidase (MAO), which is important in the decomposition of such monoamines as 5-hydroxy tryptamine (5HT) and pyrocatechol (CA). MAO-inhibitors of the hydrazine type (including iproniazid) which produce a long lasting effect are characterized by (1) a long-lasting increase of 5HT and CA in various organs (brain, heart, blood, and intestine); (2) an increase of 3-0-methyl levarterenol in the brain and a decrease of 5-hydroxy indoleacetic acid excretion as well as 3-methoxy-4-methoxy mandelic acid excretion in the urine; (3) increase in the rise of 5HT and CA, respectively, in the brain, depending on 5-hydroxy tryptophan (5HTPN) and dihydroxyphenylalanine (DOPA); (4) intensification of the central pharmacological effect of 5HTPN and DOPA (excitement and hyperthermy); and (5) antagonism against the reserpine-conditioned decrease of 5HT and CA in the brain, as well as against various pharmacological effects of reserpine on the central nervous system. It is probable that the clinical effects of iproniazid and its related compounds are partly based on MAO-inhibition too.

Dr. J. L. Rivier reported on 75 patients with angina pectoris who had been treated with iproniazid for 5 to 14 months. The initial dose was 50 mg. a day. The dose was increased every three to four days by 25 mg. to a maximum of 150 mg. a day. The effective dose was often found to be 75 to 100 mg. a day. In 50% of the patients pain subsided entirely; 25% of the patients were much improved; 16% were not improved; and 9%, all of whom had old and severe coronary lesions, died during treatment. A toxic effect of iproniazid should be excluded in these cases of death. The possibility of an orthostatic hypotension which can be elicited by iproniazid and might present a danger, at least theoretically, should always be considered. For this reason it was suggested that all patients be examined regularly and that the doses be increased gradually. Twenty-two patients with anginal pain on exertion were able to increase their physical activity with comfort during treatment and their electrocardiograms did not show any exacerbation.

Dr. H. Fleischhacker reported on 18 selected patients with angina pectoris who were given iproniazid. His results confirmed those of the previous speaker. The preparation proved to be effective only in patients with unequivocal typical attacks of angina pectoris based on severe coronary sclerosis. In others only moderate improvement was noted. Subjective cardiac complaints and sequelae of decompensation were not improved. In no case was a change of the electrocardiogram during or after treatment observed. Cardiac and other necessary treatments were given as indicated. The known side-effects were not observed in these patients. This was attributed to the fact that initial doses of only 25 mg. were given and that the dose was increased gradually to 25 mg. three or four times a day. The patients usually took this treatment for three to five weeks, the longest treatment being for four months, during which time the patient received 50 mg. daily. Special consideration was given to the evaluation of injurious effects of iproniazid on the liver. Results obtained from the serum lability test and from palpation were closely observed and in 12 patients liver biopsy specimens were examined. No evidence of liver damage was observed.

Dr. O. Zimmermann-Meinzingen gave iproniazid to 16 patients whose anginal pain was refractory to other forms of treatment. A detailed report was given on 10 of these patients whose treatment had been terminated. Of five of these whose angina pectoris was caused by coronary sclerosis two showed good improvement, two moderate improvement, and one no improvement. Two of these 10 patients had persistent angina pectoris after infarction, 1 of whom showed good improvement and 1 moderate improvement. Two others had persistent angina pectoris in the course of infarct formation, of whom one showed good improvement and one moderate improvement; and one patient who had coronary and valvular mesaortitis showed no improvement. These results were considered most encouraging and persisted after discontinuation of the other therapy aimed at dilation of the coronary vessels. A lasting favorable effect also persisted after iproniazid was discontinued. When last seen these patients were getting along well with small doses of vasodilators. No unfavorable circulatory changes were observed in those who were confined to bed. The blood pressure was not affected.

Dr. H. Walter-Büel of Münsingen reported on the use of iproniazid in the treatment of the psychoses, the treatment of which has changed greatly

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

since the introduction of chlorpromazine and reserpine in 1952. This change of treatment was concerned primarily with schizophrenic and organic psychoses. In the treatment of depressive states a similar change is now taking place with the use of iproniazid and imipramine. The speaker had used these preparations on more than 200 patients. Favorable results were obtained with iproniazid in 65% of those with menopausal, involutional, fixed psychoreactive, asthenic, and hypochondriac depressions. The drug was only slightly effective in patients with schizophrenia if they did not show a depressive component. Some loosening of the patient's frame of mind with increased activity became notable occasionally after several days, and more frequently after three to four weeks. This was often associated, although not strictly correlated, with an increase in appetite and body weight. Undesirable side-effects included vertigo, nausea, tendency to collapse, constipation, disturbances of sleep, occasionally disturbances of micturition and potency, and hyperreflexia. With a gradually increased dosage, not exceeding a daily dose of 150 mg., these side-effects remained mild. A comparison of iproniazid with imipramine is not easy. One or the other may be more effective in a single case, the factors of which are often complex. Supervision of the treatment by the physician is indispensable in view of the danger of suicide and because of the side-effects.

Dr. C. G. Tauber of Bern, Switzerland, reported on a series of more than 300 psychiatric patients, 134 of whom had been treated with iproniazid for 6 to 18 months. The drug was highly effective in 65% of those with depressive states of various origin. The best results were obtained in patients with endogenous depression, 85% of whom showed improvement. In many patients iproniazid therapy may be an adequate substitute for electroshock therapy and is not as frequently followed by recurrence as electroshock therapy. In about 10% of the patients, too early withdrawal of the drug was necessary because of a tendency to collapse or too strong a psychic action. About 10% of the patients were therapeutic failures. With a maximal daily dose of 150 mg. and with careful adaptation of the dosage, the side-effects were controllable or could be compensated by the administration of other drugs with a symptomatic action. Severe accidents, such as liver damage, did not occur among the 300 patients. The duration of treatment varied from three weeks to over nine months. Careful establishment of indications is indispensable for ambulatory treatment with iproniazid (all agitated patients are excluded) and so is continued supervision. Psychotherapeutic care and guidance is also important. New drugs with an analogous action are being developed.

Dr. V. E. Frankl reported that a woman with a phobic condition, who was undergoing psychotherapy, returned one day and stated that psychotherapy was no longer necessary since suddenly she had become free of fear and that this happened when she had to take iproniazid for tuberculosis. Since then he has treated 18 psychiatric patients with iproniazid, some of whom had been under observation for many years. In one of these patients the effect of the drug could be compared only with the therapeutic effect resulting from electroshock which the patient had been given several years previously. A woman with a compulsion neurosis of long standing, after taking iproniazid, described the characteristic effect of a so-called pharmacological leukotomy, which is known to result from the administration of certain tranquilizers or from such adrenergic agents as amphetamine. In this patient the effect of the pharmacological leukotomy was far superior to that of a surgical bilateral leukotomy which the patient had undergone earlier.

BRAZIL

Bleeding Time.—Dr. Cecy Barros and co-workers at the Hospital das Clinicas in São Paulo found that between the fingers and the lobes of the ears there is a significant difference in bleeding time, but there is no difference between the right and the left side of the body. On different days, in the same person, the bleeding time may show a significant difference. The mean bleeding time, in 100 normal subjects, was 1.75 (± 0.27) minutes. The bleeding time when prolonged, in almost every instance, indicated platelet deficiency. There were cases, on the other hand, with platelet deficiency and normal bleeding time, and some with a normal platelet count and prolonged bleeding time. The bleeding time, by itself, is not an index of the hemostatic capacity of the vascular and blood systems. In addition one needs a platelet count, a tourniquet test for vascular fragility, and other tests.

Uterine Rupture After Cesarean Section.—Drs. Antônio Guariento and co-workers at the Hospital Leonor Mendes de Barros in São Paulo studied a series of 855 patients who had had a previous cesarean section; 341 of them had a total of 401 iterative cesarean sections and the remaining 514 had 744 vaginal deliveries. In this entire series 30 uterine ruptures occurred in and 6 outside the hospital. In 9 of the 36 the scar was that of a classical cesarean section, and in 27 of a section in the inferior segment of the uterus. In 10 patients the rupture was diagnosed and a laparotomy was promptly performed. The classical symptoms and signs are often absent, and the diagnosis is sometimes made only during another cesarean section or by examination of the cavity after a vaginal delivery. The presence of meconium in a bloody urine indicates uterine rupture complicated by injury to the bladder. In spite of blood transfusion, improved anesthesia, and antibiotics, uterine rupture is still a serious threat to both mother and child. In this series there was one maternal death, in the third day of puerperium, and 15 fetal deaths. Conservative surgical measures such as hysterorrhaphy should be used whenever possible. If conditions do not allow it, a subtotal hysterectomy best serves the interests of the mother. The authors performed 31 hysterorrhaphies and 5 subtotal hysterectomies. They do not favor routine sterilization but treat each case on its merits.

CANADA

Society for Clinical Investigation.—At the annual meeting of the Canadian Society for Clinical Investigation in Vancouver, British Columbia, D. M. McLean of Toronto pointed out that few of the so-called nonparalytic cases of poliomyelitis in that area had been associated with poliovirus. In 1958 a common finding in children with aseptic meningitis in Toronto had been the isolation of Coxsackie virus B5 from feces samples. Enterovirus infection had also been responsible recently for a wider variety of syndromes, including pericarditis but not isolated myocarditis as found in southern United States.

D. Fraser of Toronto had studied two children with hypophosphatemic–vitamin D refractory rickets and found nothing wrong with the renal tubules. He thought that the excessive renal clearance of phosphorus was the result of secondary hyperparathyroidism, possibly due to defective intestinal absorption of calcium. D. McPherson of Vancouver had performed calcium infusion studies on normal subjects and patients with osteitis deformans and suggested that the labile storage pool of calcium in the skeleton was abnormally large in this disease with a faster bone blood flow of calcium.

P. Constantinides of Vancouver described a sulfated polysaccharide, known as Paritol-C, as a promising agent for the control of hyperlipemia. Given intravenously in nine patients with hypercholesteremia and hyperlipemia, it normalized the serum lipid levels in eight and the serum cholesterol levels in five, and resulted in clinical improvement. E. McGarry of Montreal had produced antibodies to anterior pituitary hormones in animals and found on immunochemical evidence that porcine, human, and bovine growth hormones were species-specific. Such antigen-antibody systems could be used to measure the levels of anterior pituitary hormones in body fluids. E. H. Venning of Montreal measured in vitro secretion of steroids from adrenal glands obtained from patients with pituitary basophilism or virilization. Adrenals from patients with virilization secreted less hydrocortisone and cortisone than did those from patients with pituitary basophilism, and there seemed to be an increased production of 17-ketosteroids in the virilizing syndrome.

J. C. Laidlaw of Toronto described experiments designed to relate findings of changes in steroid secretion during pregnancy with sex-hormone changes. Women with adrenocortical hypofunction who were taking hydrocortisone were given estrogen and progesterone. Estrogen administration produced no increase in hydrocortisone secretion in these, or in normal subjects who were given ACTH, but caused the same changes in metabolism of the steroid as occur in pregnancy. Progesterone did not cause these changes, and it was concluded that the alterations in hydrocortisone disposition in pregnancy are largely due to increased estrogen secretion. W. I. Morse of Halifax, Nova Scotia, showed that whereas oral tolerance of glucose was impaired in obesity of long standing, there was no difference between obese and normal subjects as regards intravenous glucose tolerance. The abnormal results in the oral test were not due to impaired glucose removal. R. A. Palmer of Vancouver made a plea for rectal administration of carboxylic acid resins in the control of hyperkalemia. In 17 patients with acute or chronic renal failure 25 Gm. of the resin mixture given by high enema at 4-hour to 12-hour intervals proved an efficient method of removing potassium. H. Cross of Kingston, Ontario, gave large rapid infusions of magnesium sulfate to hypertensive and normal subjects, noting a drop in blood pressure in the hypertensive but not in the normal subjects and an increased urinary excretion of calcium, sodium, and chloride ions but no change in phosphorus excretion. The hypertensive subjects showed increased excretion of potassium and increased glomerular flow rate and renal plasma flow. A. S. V. Burgen of Montreal followed the fate of intravenously injected radiomagnesium in the body. A rapid urinary excretion gave place to a slower one, with a total turnover time of 115 minutes. The site of the rapidly exchangeable magnesium is unknown, but the slowly exchangeable magnesium must be in skeletal muscle or bone. Serum magnesium was a poor indicator of the 24-hour exchangeable magnesium.

College of Physicians and Surgeons.—At the 28th annual meeting of the Royal College of Physicians and Surgeons of Canada in Vancouver, British Columbia, N. M. Lefcoe of London, Ontario, demonstrated a high degree of correlation between the timed vital capacity in patients with chest disease and the radiologist's assessment of the presence of emphysema, but the presence of a contracting lung lesion destroyed the correlation. E. R. Yendt of Toronto discussed the diagnosis and treatment of

20 patients with renal hypertension, and stressed the value of differential tests of renal function in diagnosis. In essential hypertension there was less than 10% difference in the volume and sodium concentration of urine secreted by the two kidneys, whereas in renal arterial disease the volume showed 50% difference and the sodium concentration 15%. A. E. Thomson of Winnipeg, Manitoba, stressed two problems in the treatment of acute renal failure: (1) use of adrenergic blocking agents to overcome peripheral vasoconstriction (he had used phenoxybenzamine at the onset with success); and (2) the difficulty of dealing with potassium intoxication, particularly as seen in traumatically injured patients. R. C. Dickson of Halifax, Nova Scotia, reported the successful use of potassium perchlorate as a thyroid depressant in hyperthyroidism and in euthyroid persons with angina pectoris. With a dosage of 200 mg. five times a day toxic effects were few. The drug was also of diagnostic value in struma lymphomatosa. H. McIntosh of Vancouver conducted a search for parathyroid tumors, particularly in patients with recurrent renal calculi, and recommended the intravenous infusion of calcium as a diagnostic aid. In the normal person the serum phosphorus level rises and the urinary phosphorus level falls, but in hyperthyroidism the serum phosphorus level does not rise.

J. A. Dauphinee of Toronto warned that hepatolenticular degeneration might be mistaken for paralysis agitans, and urged the examination of the eyes by slit lamp as a screening measure. In treating these patients penicillamine was more effective in removing copper than dimercaprol, but it might deplete the body of other trace elements. J. B. Dosseter of Montreal described the medical aspects of the first successful renal transplantation in Canada, performed on identical twins. Secretion of urine began almost as soon as the donor kidney had been sutured in place. Bilateral nephrectomy was performed five months later. Six weeks after the first operation the patient was ambulant and free from symptoms. P. Constantinides of Vancouver induced atheroma in rabbits by cholesterol feeding and showed that stilbestrol arrested the progress of the lesions, while vanadium and starvation had no effect, and linoleate had a partial effect. Stilbestrol caused toxic liver effects in half the rabbits. G. Monckton of Edmonton, Alberta, found in a patient with familial periodic paralysis that potassium was not stored in the liver as had been suggested by radioactive potassium studies but that before and during attacks of paralysis there was marked sodium retention with a drop in urinary sodium. A diet low in sodium controlled the paralysis.

W. Pisesky of Edmonton had found in experiments on rats that triethylene thiophosphoramide retarded wound healing, while norethandrolone counteracted this. K. S. Morton of Vancouver followed up 62 patients with traumatic dislocation of the hip and noted that the chief factors determining the result were severity of injury and delay in reduction. F. P. Dewar of Toronto analyzed 145 fractures of the carpal scaphoid and showed that, provided such a fracture was immobilized in plaster, it was difficult to prevent it from healing. Conservative treatment is the only acceptable one, even with missed fractures. T. K. Goodhand of Winnipeg had replaced an entire ureter in dogs with an ileal loop, removed the contralateral kidney, and killed the animals 4 to 12 months later. The isolated loop was a satisfactory substitute for the ureter, and it seemed better to replace all rather than part of the latter. The blood urea level soon returned to normal and chloride reabsorption by the ileum was not a problem.

Vitamin C-Fortified Milk.—Last year a series of cases of infantile scurvy was reported from Toronto and Winnipeg. Medovy recommends (*Canad. M. A. J.* 80:213, 1959) that all evaporated milk be fortified with vitamin C in view of the decline in breast feeding, the reluctance of some mothers to give orange juice, and the general confusion in the lay mind about vitamin concentrates. One firm has produced a milk incorporating 75 mg. of ascorbic acid per 15-oz. can, and the product has been subjected to rigorous tests in the Winnipeg Children's Hospital without loss of vitamin C content. Two patients who had scurvy were treated solely by the fortified milk, with prompt clinical improvement supported by radiologic evidence.

Prepaid Optometry.—A complete plan for optometry on a prepaid basis has recently been started by the Canadian Association of Optometrists, which has organized a nationwide nonprofit organization called Canadian Optometric Services, Inc., operating under a government charter. Commercial, industrial, or professional groups can enroll, and services include examination, refraction, and provision of lenses and frames. The subscriber has a choice of optometrists. The cost of plans will vary depending on their type and extent of coverage, but a basic plan is expected to run at 65 to 80 cents per person per month.

Prescription Insurance.—Another experiment in prepaid care started in March, 1958, in Essex County, Ontario, when Prescription Services, Inc., began as the first known pharmaceutical prescription plan in Canada. It serves an area with a population of 200,000, and agreements with all but 7 of the 75 pharmacies involved have been signed. A progress report on the first six months shows that of 548 persons enrolled in the last month 104 had 211 prescriptions filled with an average ingredient cost of $1.86 and average retail price of $3.72. Organized labor has been favorable to the new plan, but management has been frank in its opposition to providing another fringe benefit for employees. Sponsors believe that the plan can succeed with slight modifications.

Schizophrenia.—Osmond and Hoffer recently reviewed research into the chemical nature of schizophrenia (*Canad. M. A. J.* 80:91, 1959). Steps in the studies included recognition of a relation between mescaline intoxication and acute schizophrenia; discovery of the relation between the chemical constitution of the former and that of epinephrine; reports by some asthmatics that when their epinephrine for self-administration turned pink they experienced hallucinations after its use; and the discovery that one of the products of pink epinephrine was adrenochrome, which in normal subjects produced schizophrenic sensations. Another breakdown product of epinephrine is adrenolutin, and either of these breakdown products may prove to be the naturally occurring mescaline-like substance responsible for the sensory changes in schizophrenia. It has also been shown that schizophrenics are less able to remove adrenochrome from the blood than are normal persons. It seems that d-lysergic acid (LSD-25) retards the destruction of adrenochrome and permits its accumulation in the body.

INDIA

Mongolism.—Dayal and Agarwal (*Indian Journal of Child Health*, vol. 7, December, 1958) stated that mongolism is not so uncommon in this country as is usually believed. They observed 18 cases in children between 3 months and 11 years of age, all of whom showed microcephaly and brachycephaly. Thinning of the skull bones was evident in 12, and 2 also showed nonclosure of sutures. The fingers and toes showed the deformities commonly described, i. e., increased space between the first and second digits, short digits, and a short terminal phalanx of the fifth digit which was turned inward. The sole and palm creases showed deviations from normal in about half the patients. Macroglossia was a universal feature, the tongue showing fissures and conforming to the "scrotal type" in most patients, although in seven there were no fissures on the tongue. In 16 the ears were small and turned forward. An interventricular septal defect could be diagnosed clinically in only one patient. This was later confirmed by x-ray and electrocardiogram. The typical oblique palpebral fissures and epicanthic folds were present in all patients. In one the orbits were winged and obliquely set and one had nystagmus. Congenital cataract was present in two and strabismus was seen in one.

All the children showed severe mental retardation and the various milestones in the physical development were delayed. No correlation could be detected between parity, parental age, and idiocy, and there was no history of such maternal illnesses as mumps, influenza, or rubella in any of the cases. Consanguinity was found in one case only. Thus, in this study, late closure of fontanelles and persistence of frontal sutures was not a frequent finding as is commonly described and no widening of fissures and foramina could be demonstrated. No common etiological factors could be established.

Tetralogy of Fallot.—R. H. Betts and co-workers (*Indian Journal of Surgery*, vol. 20, December, 1958) stated that the clinical findings in patients with the tetralogy of Fallot are variable. The two dominant lesions are the pulmonic stenosis and the interventricular septal defect. The authors operated on 79 patients with this condition and 13 died. An autopsy was performed on 11, and it was concluded that such patients, operated on before the age of 3, suffer from an extreme degree of disability. The authors usually deferred the operation when there was a possibility that the child would live to the age of 3 or older. All risks are increased in infants and the death rate in children below 3 years of age in this study was 50% as compared to 12.5% for those above 3. Angiocardiography and cardiac catheterization were not usually performed on the severely incapacitated child under 3 years of age as they were believed to increase the risk. This measure may, however, be justifiable in some cases in order to determine the exact site of obstruction preoperatively so that the proper operation can be planned. This is especially important in children who are not good subjects for the Blalock operation due to a small subclavian artery, in which case a Pott's operation, if there is a left aortic arch, or a direct pulmonic valvotomy, if the obstruction is predominantly valvular, would be advisable. The pericardium was not opened routinely but the extent of the pulmonary stenosis was assessed by feeling for the cone of the pulmonary valve and the easily obliterated thrill through the intact pericardium.

The most frequent cause of death in this series was faulty postoperative management. Cerebral thrombosis is a common complication in deeply cyanotic patients and its risk increases if there is marked dehydration. This complication developed in four patients, two of whom died. Three other deaths were due to errors in management—one patient developed atelectasis of the left lung which progressed to early bronchopneumonia, another developed a severe diarrhea, and one had a persistent paralytic ileus. On the 5th postoperative day a laparotomy was performed on the last mentioned patient. No cause for the ileus was found. The gastric aspiration tube became blocked on the next day and a large amount of material was vomited. Some of it was aspirated and the child died soon after. In three of the fatal cases, there was an error in diagnosis. One child, less than 2 months of age, was believed to have tetralogy of Fallot and cerebral thrombosis. Pott's operation was performed but the child died after two weeks and at autopsy was found to have not a tetralogy but a transposition of great vessels with a small interventricular septal defect. The cerebral symptoms were due to the presence of a large porencephalic cyst which was the cause of death.

Another patient was found to have pulmonic stenosis only and should have had a valvotomy instead of a shunt operation. The third patient was diagnosed preoperatively as having pulmonic stenosis with an atrial septal defect. At operation he was thought to have both valvular and infundibular stenosis and a pulmonary valvotomy was performed. Autopsy showed that, instead of a pure pulmonic stenosis, the child had a tetralogy of Fallot with valvular and infundibular stenosis, an atrial septal defect, and a patent ductus arteriosus. In two patients errors in operative technique caused death. In one, a Blalock type of anastomosis was performed but was inadequate as the left pulmonary artery was extremely small and friable. The anastomosis was occluded by a thrombus. An anastomosis should have been done on the right side as the right pulmonary artery was of normal size. A preoperative angiocardiogram would have helped in this case. In the second case laceration of one of the cusps of the aortic valve was produced accidentally by the valvulotome and caused an aortic insufficiency which contributed to the patient's death.

Errors in choice of operation accounted for two deaths. One was thought to have a pure pulmonic stenosis and a valvotomy was performed, but he had a tetralogy of Fallot and should have had a shunt operation. Another was an infant of 7½ months and a Blalock operation was performed. The vessels were small and at postmortem the anastomosis was found to be completely occluded by a thrombus. The child also had a combination of valvular and infundibular stenosis and a valvotomy would have given him enough relief so that a shunt operation could be done when he was older. In two the cause of death could not be determined and associated defects probably contributed to the death of others. Thus one child of 7½ months had a right aortic arch and a marked dextroposition of the aorta. The second had an extreme dextroposition associated with a diminutive pulmonary artery. Two others had peculiar valve-like structures within the interventricular septal defects, causing obstruction to the blood flow and imposing an additional burden on the right ventricle.

National Register.—The government is compiling a national register of all qualified scientific and technical personnel of the country. The purpose of this register is to provide comprehensive and authoritative information on national resources of scientific and technical manpower; to serve as a clearing house for information on resources of and requirements for scientific and technical manpower; to develop a special section of the register to maintain current information on Indian nationals studying or working in technical fields in foreign countries; to provide information on persons having highly specialized training and experience, when an appointing authority finds it difficult to get suitable candidates to respond to public advertisements; and to assess the gaps in the training and utilization of scientists and technologists through technical manpower research. The National Register Unit prepares study reports based on the information contained in the register. The register lists those (1) holding at least a postgraduate degree in a science, (2) holding at least a bachelor's degree in agriculture, veterinary medicine, and other fields, (3) holding a degree in engineering and technology, and (4) who are medical specialists.

Hypothermia in Surgery.—Saini and Bett (*Indian Journal of Surgery*, vol. 20, December, 1958) used hypothermia of various degrees in 98 patients, cooling the skin surface by blankets. Of these, 66 had tetralogy of Fallot and hypothermia was used to improve the operative risk. Many were deeply cyanotic and many had rapid pulse rates. The range of temperature varied from 92 to 88 F. Six patients with pulmonary stenosis were also operated on under hypothermia. Hypothermia here was used as an adjunct, as it was also in another group of nine patients with acquired heart disease. The operative mortality under ordinary anesthesia is high in such cases; three of five patients with mitral stenosis were saved by operation under hypothermia. The remaining four had constrictive pericarditis and hypothermia helped to reduce the operative risk. Hypothermia was also used in operations where local occlusion of circulation was necessary. The total number of deaths in the whole series was 18, and of these 4 could be attributed to hypothermia. One patient with mitral stenosis developed ventricular fibrillation; cardiac arrest occurred in a patient with atrial septal defect; excessive bleeding from the surface of the heart led to death in a patient with constrictive pericarditis; and an apparently acidotic syndrome proved fatal in a patient with atrial septal defect.

Vasectomy for Sterilization.—Ohri and Jhaver (*Indian Journal of Surgery*, vol. 20, December, 1958) studied the changes in the testes of rats and men after vasectomy. The first 50 operations on human subjects were by the standard two-incision technique under local anesthesia. Later, one central scrotal incision was used, about 1 cm. in length, through which bilateral vasectomy was done. Patients were not admitted to hospital and contraceptives were advised for about six to eight weeks, after which the semen was examined for living spermatozoa. They were followed up for six months to four years.

Old male rats were used for the experimental study. They were divided into three groups. The testes were removed from the first group for histological examination. The second group served as controls, their testes being removed for study at the end of six months, and in the third group, vasectomy was performed and the rats subjected to orchiectomy at varying intervals. Study of the whole group covered about six months. The rats in the first and second group showed normal testicular tissue on histological examination with active spermatogenesis, thus showing absence of change in the second group due to age during the period of experiment. In the third group, within two weeks after the operation, the seminiferous tubules started showing degenerative changes associated with congestion of the stroma. The degenerative changes increased for the first eight weeks. Eight weeks after the operation, the appearance was striking, consisting of islands of normal seminiferous tubules surrounded by degenerated tubes and vice versa, representing active regeneration of a focal type. The interstitial tissue, from the 10th week on was more noticeable, its proliferation being marked toward the end of the experiment.

After vasectomy in men, 6 complained of diminution of sexual capacity, 86 noticed an increased sexual strength and desire, and 198 claimed that their sexual power remained unchanged. There was weight loss in 18 patients after operation, no change in weight in 160, and a gain in 112. Relief from the anxiety from further additions to the family was probably the cause of the pleasant mental reaction to the operation, which was in some cases associated with increased sexual capacity; 268 felt very happy after the operation. The reaction of the wives of these men varied; 96 felt happy because of freedom from further childbearing, 190 showed no particular reaction, and 4 reported conception after the operation. Failure of the operation in controlling conception was specially noticed in cases where plain catgut was used to ligate the two ends of the vas, rapid absorption of which probably allowed reestablishment of the lumen.

Viral Encephalitis.—Mathur and Prasad (*Journal of the Indian Medical Association*, vol. 32, Jan. 16, 1958) analyzed a series of 161 cases of viral encephalitis seen in an epidemic, July to September, 1958. The peak was reached between July 7 and 21. The largest number of deaths however were reported in the last week of September. Persons belonging to both upper and lower economic strata were affected. Often more than two members in the same family were attacked. There was no report of person-to-person transmission in the hospital wards. Most of the patients (89%) were below 8 years of age (range 1 month to 35 years). The onset was usually sudden, with restlessness, vomiting, diarrhea, and a temperature of 102 to 105 F (38.99 to 40.56 C). Convulsions and twitchings then appeared, the child talked incoherently or became delirious, and lapsed into semiconsciousness or unconsciousness. The fever was most commonly continuous or remittent but in some it was intermittent. It returned to normal by lysis. A secondary rise was seen in 15.5% of the patients after a complete remission lasting two to four days; 1.8% also showed a tertiary rise of temperature. Two patients showed blindness and one had dimness of vision. One had myoclonic movements and two developed tremors of a rhythmic Parkinsonian type which disappeared on recovery. Two patients showed spastic paraplegia at the onset and one had a flaccid paraplegia. Two had hemiparesis. None of these had any residual effects after recovery.

More than half the patients had nuchal rigidity with a positive Kernig's sign and 42.2% had an extensor plantar reflex. Pulmonary involvement was common and three patients died of acute pulmonary edema. Ophthalmoscopic examination in 60 patients revealed optic neuritis in 3 and pallor of the disks in 2. Clinically the patients could be divided into a fulminant (34.8%), moderate (33.5%), and mild (31.6%) type. More than 67% had polymorphonuclear leukocytosis. A low blood sugar level was found in only 15%. The cerebrospinal fluid was under increased pressure on lumbar puncture in 76%. The most common change was pleocytosis to the extent of 5 to 50 cells. In addition to symptomatic treatment, the patients were divided into seven groups and given different drugs (tetracycline, penicillin, chloramphenicol, ACTH, a combination of tetracycline and ACTH, ACTH with penicillin, and normal saline solution). The results with normal saline solution (given intramuscularly) and ACTH alone were the best. There were 45 deaths, giving a mortality of 27.9%. Among the 112 patients who were discharged as cured, 8 had a relapse. No residual effects were noted in about 70% of those who were discharged as cured and could be followed up for one to three months.

NORWAY

Iproniazid for Psychosis.—Haug and Kolstø (*Nord. med.* 60:1789-1794 [Dec. 11] 1958) treated 22 chronically psychotic male patients with iproniazid. Most of these patients were schizophrenics. All of them presented long-standing apathy and/or depression, with little or no variation in the clinical course of their illnesses. The patients were given 50 mg. of iproniazid three times a day for 10 weeks. Significant changes in behavior were observed in 16, and in 6 no changes were noted. With the exception of one patient who became more depressed, all showed a definite increase in the general activity level and an elevation of mood. From a practical clinical point of view, however, only 6 could be classified as improved; 10 became overtly aggressive and hyperactive to an extent that made them difficult to manage in the wards. In several, hallucinations were intensified. During the trial period, treatment was discontinued in 7 and the dosage reduced in 11 because of severe psychiatric and somatic complications. One patient was on the verge of delirium. One developed melena. Another, who had never shown signs of heart disease, died of myocardial infarction. Hypotension, dizziness, and fainting occurred in some. Hyperreflexia, constipation, and anemia were common but not severe. Chromatographic analysis of the spinal fluid of five patients showed an increase of the albumin fraction. The authors cautioned against uncritical use of iproniazid to activate chronically psychotic patients. The drugs tended to reactivate violent psychotic outbursts, repeating the acute early phases of the illness, and its use was complicated by widespread disturbing and dangerous somatic complications. Further study is needed before the usefulness of the drug in the treatment of chronic psychotic patients can be determined.

SWEDEN

Endocrinological Institute.—The only hospital department in Europe specializing in endocrinological research was inaugurated in January at the Stockholm Carolinian Hospital, under the chairmanship of Professor Rolf Luft. One half of the floor space is occupied by laboratories. The most important task of the new institute will be further research in endocrinology. Important projects include studies on diabetes, thyroid diseases, and hormone treatment of certain types of cancer.

Protons Used in Brain Surgery.—Proton rays were used in brain surgery at the Upsala University in December. Now the operation has been judged successful. The patient was a 55-year-old man suffering from chronic depression, and the operation was the result of close teamwork between neurosurgeon, histopathologist, radiologist, and the personnel of the synchrocyclotron department of the institute. Experiments with the use of a proton ray as a surgical instrument were first made at the University of California in Berkeley, where a different procedure from the one used at Upsala was followed. This operation, the first of its kind on a human being, was preceded by extensive animal experiments on mice, rabbits, and goats which were subjected to careful pathological examination in order to ascertain the possible aftereffects. The results were reassuring. Professor Lars Leksell, a neurosurgeon of Lund University, believes that the method will be specially useful for treatment of chronic pain, paralysis agitans, and certain psychic disorders.

The protons, with an effect of 190 million electron volts, cut off deep-lying nerve paths in the brain. The advantages over conventional brain operations is that this procedure diminishes the hazards and complications involved and shortens the time of recovery. The new type of operation is not painful and takes place without anesthetics. Hospitalization is not required. The Upsala patient was in touch with the operating team by means of a microphone, the operating crew watching the procedure by television in order to avoid being subjected to ionizing radiations. The treatment was interrupted about 40 times to change the angle of approach of the ray, and the patient was thus never alone more than about a minute at a time. Dr. Börje Larsson was the nuclear scientist responsible for the instruments used. The new method is not likely to be generally used for many years. Several such operations, however, have been planned.

UNITED KINGDOM

Reducing Tablets.—Drs. A. Foster and C. Seager of Barrow Gurney Hospital are compiling data for the Poisons Board on the use of reducing tablets, which they claim are producing drug addicts. Women pay an average of $1 weekly for the tablets, which are sold at the rate of one million a month. The Poisons Board is considering making a number of reducing preparations available only on prescription. A woman recently appeared before the courts accused of forging doctors' prescriptions to get reducing drugs, which she had been taking for five years. Her weight had dropped from 154 to 84 lb. (69.9 to 38.1 kg.), and she suffered from severe insomnia. She finally concluded that it was "better to stay fat and happy."

Electronic Pacemaker Sutured into the Heart.—One of the major hazards of open-heart operations for the closure of ventricular septal defects is damage to the conduction mechanism and consequent heart block. This has been dealt with by Ross and co-workers by direct stimulation of the ventricles by an electrode sewn into the heart and connected to a pacemaker (*Lancet* 1:392, 1959). A 7-year-old girl was operated on by Sir Russell Brock for closure of a ventricular septal defect. A complete cardiac bypass was maintained for just over 30 minutes, and the heart was arrested for this period with potassium citrate. The defect was closed, but shortly afterward fibrillation and finally heart block occurred. The bared ends of two electrodes, one acting as a stimulator and the other as a spare, were sutured with fine silk into the anterior surface of the right ventricle, about 2 cm. apart. An indifferent electrode was implanted into the right pectoralis major muscle. All three leads, which were 2-ft. lengths of plastic-covered six-strand fine wiring used in telephone equipment, were exteriorized by separate incisions and anchored to the skin. The ends were connected to a battery-operated artificial pacemaker adjusted to maintain a rate of 120 beats per minute, the usual postoperative rate of patients who undergo similar operations without developing heart block. The pacemaker, set to deliver 4 volts, which was just above the minimum voltage necessary to cause the heartbeats to follow the pacemaker consistently, accompanied the patient back to the ward. An electrocardiograph-monitoring oscilloscope was connected to the pacemaker.

The heart block and its management by the pacemaker was the only postoperative complication. On the second postoperative day the child suddenly became pulseless for 10 seconds, presumably due to cardiac arrest, but quickly recovered. The pacemaker was switched off on the fourth day and the heart maintained its own rate of 80 to 90 beats per minute until the eighth day, when it was necessary to use the pacemaker again. It was used intermittently until the 11th day. Then 5 mg. of isoproterenol was given orally three times daily, and the pacemaker was disconnected. The isoproterenol therapy was stopped 11 days later. On the 21st day, when it was evident that the heart was in spontaneous sinus rhythm, the electrodes were removed by slight traction. The girl was discharged a month later and was well when last seen.

New Type of Pneumoconiosis.—During a survey by the Pneumoconiosis Research unit of the Medical Research Council on random samples of men of known occupation, a new type of industrial pneumoconiosis was brought to light (*Tubercle* 39:399, 1958). The investigations included a detailed industrial history, measurement of the ¾-second forced expiratory volume (FEV 0.75), and a chest film. The films were read by experts without any knowledge of the occupational or medical history of the subjects. One occupational group, designed as a control for the industrial groups, consisted of men who, as far as was known, had not been exposed to dust or fumes likely to damage the lungs or cause pneumoconiosis. When the data for this group were tabulated, however, it was found that a few of the chest films showed evidence of pneumoconiosis. These were from men who had worked for 40 years or more on the footplate of a train as a driver or stoker. The FEV was above the average for men of similar age in such occupations as agriculture. Although there was no evidence of pulmonary disability, the chest films showed unmistakable signs of pneumoconiosis. It was therefore concluded that after 40 years of driving on the footplate of a train sufficient dust is retained by the lungs to be roentgenologically visible.

New Viruses.—During an outbreak of a respiratory illness resembling coryzal bronchitis in a residential nursery in Sheffield, Sutton and co-workers (*Lancet* 1:395, 1959) identified two new virus strains. Throat swabs from the children were inoculated into monkey-kidney tissue cultures. Hemagglutinins for chicken and human cells appeared in the mediums and two strains of virus, hitherto unreported in Europe although recently described in America, were identified. These strains, known as HA1 and HA2, belong to the myxovirus group. They were detected by the technique of hemadsorption.

Twin Pregnancy in a Double Uterus.—The extremely rare case of a twin pregnancy in a double uterus was reported by Dr. N. Kennedy, a general practitioner of Kent. Twins were diagnosed antenatally in a woman with two cervices who had had four previous pregnancies. She went into labor spontaneously at the expected time and after 12 hours was delivered of an asphyxiated infant who died shortly afterward. After delivery the right side of the mother's abdomen was seen to be empty and uterine contractions ceased. The remaining fetus lay obliquely with the vertex presenting high over the pelvic basin on the left. Three weeks later the second twin was born via the second cervix. A hysterosalpingogram taken subsequently revealed two uteri with separate cervices, the left larger than the right, showing that both uteri had been gravid. Several interesting points arise from this case: One uterus went into labor independently of the other; the right uterus retracted during the expulsion of the first twin, while the left uterus was undergoing first-stage contractions; and lactation was absent after the birth of the first twin but established itself shortly after that of the second.

Television Angina.—In a letter to the *British Medical Journal* Dr. G. Rose reported a new condition, observed at a clinic for coronary diseases, which he calls "television angina." This affected 20% of those patients with angina pectoris who watched television programs and was provoked by seeing violent incidents on the screen. Among those liable to emotionally produced attacks only a few could enjoy viewing television without cardiac pain. In some patients television angina was the only type of rest pain. Rose stated that commercials were innocuous, but Westerns and plays or films depicting violence or excitement often provoked anginal attacks.

Extravenous Injection Not Negligent.—Last June a judgment was given in favor of a patient who sued the North Liverpool Hospital Management Committee for negligence in the administration of thiopental for varicose vein operation. It was claimed that the thiopental, which should have been given intravenously, entered the surrounding tissues and produced an abscess. The case against the committee was that it was vicariously responsible for the negligence of the anesthetist. The judge awarded damages of $1,218. The case was taken to the court of appeal. The patient was an exceedingly fat woman; the anesthetist had inserted his needle obliquely over a vein and aspirated to make sure that the needle was in the vein. Blood entered the syringe, and he then injected 5 ml. of thiopental solution. As this produced no anesthetic effect, the needle was withdrawn. Further attempts were made in both arms to locate a vein but without success. It was assumed that the thiopental had entered the tissues and not the vein, particularly in view of the later development of an abscess.

One error alleged was that the anesthetist should have aspirated blood repeatedly into the syringe during the injection to make sure the needle remained in the vein, but the judge found in the anesthetist's favor on this point. The second error alleged was that he failed to ask the patient if she felt any pain. The fact was that she did not, nor was there any swelling at the time; so even if she had been asked she would have replied in the negative. The court of appeal decided that there was no evidence of negligence on the part of the anesthetist.

Improved Obstetric Care.—The committee set up in 1956 to review the organization of the maternity services of England and Wales (Ministry of Health Report of the Maternity Services Committee, Her Majesty's Stationery Office, 1959) reported that the care of a woman in pregnancy and childbirth is divided between the three separate parts of the National Health Service, namely, the hospitals, the general practitioners, and the local health authorities. In general the system works reasonably well, although overlapping and impairment of service are at times inevitable. The report recommends that in future only general practitioners who are qualified and experienced in obstetrics should be paid for maternity work. At present doctors on the obstetric list of the National Health Service receive $20.60 for the complete obstetric care of a patient. The fee is $15 for those not on the list. The committee recommends that only doctors on the obstetric list, of which there are 14,400, should receive payment for maternity work. It is suggested that in the future admission to this list should be more selective. A six-month obstetric internship is regarded as a minimum qualification, and to remain on the list a doctor should have conducted at least 60 obstetric cases in the preceding three years.

Obstetrics, formerly practiced by many general practitioners, has now become highly specialized. There are 737,704 births yearly in England and Wales, nearly 65% of which are in hospital. To remain competent a doctor should attend a minimum of 50 cases a year but, allowing for hospital births, there cannot be more than 12 or 13 cases for each practitioner and this is insufficient to maintain obstetric skill. The suggestion is therefore made that a higher standard should be required. Fewer doctors would then practice obstetrics, and those who did would treat more such patients than at present. Remuneration should be correspondingly higher. The report also advocates the supervision of maternity units staffed with general practitioners by specialized obstetricians, without their trespassing too closely on clinical freedom. This would be difficult to achieve and would probably be resented by general practitioners. Many women, particularly of the middle class, prefer to have their second babies delivered at home rather than in hospital.

Other recommendations made by the committee include the provision of sufficient hospital accommodation for 70% of all confinements and antenatal beds for 20 to 25% of these. As it costs the patient less in hospital than at home it is suggested that the mother confined at home should receive a maternity grant of about $14. The committee considers that obstetric care should still be under the tripartite administration of hospital, general practitioner, and local health authority. To unify it under a single authority would create more problems than it would solve, but it suggests that the general practitioner–obstetrician could eventually replace the local health authority's medical officer in providing antenatal and postnatal care. The expectant mother should be instructed in child care and hygiene and should be provided with a maternity aid service after the birth of the baby. There should be sufficient premature-baby units to give country-wide coverage, and enough obstetric "flying squads" to attend all emergencies that cannot wait for hospital care. Resuscitation equipment, which should be kept in all hospitals, should be available to general practitioner–obstetricians. The committee considers that these should have access to maternity beds in hospitals, although few do at present. A final suggestion is the introduction of a national "maternity card" on which the mother's complete obstetric history could be recorded.

Idiopathic Hypoproteinemia.—Generalized edema may sometimes occur as a result of alteration in the metabolism of plasma proteins, resulting in severe hypoproteinemia. The patient appears to eat and absorb protein, to synthesize albumin, and to show no evidence of protein loss. Gordon, Schwarz, and Jarnum, working independently, showed that in this condition, which is known as idiopathic or hypercatabolic hypoproteinemia, the proteins are lost from the gastrointestinal tract (*Lancet* 1:325, 327, 1959). These workers have succeeded in labeling polyvinylpyrrolidone (PVP) with radioactive iodine (I^{131}). This substance, with a molecular weight of 40,000, is unaffected by proteolytic enzymes, and is used as a plasma expander. PVP with I^{131} is useful for measuring the permeability of the alimentary tract to serum proteins. The fecal PVP–I^{131} content was measured after a single injection in 13 patients with idiopathic hypoproteinemia. In all of them there was excessive loss into the gastrointestinal tract, showing that in these patients there was an abnormal permeability of the tract to macromolecules. Albumin synthesis, in terms of the degradation of I^{131}-labeled albumin, was high in all cases, showing that the edema was not due to lowered blood albumin level. The edema would thus appear to be due to protein loss in the gastrointestinal tract. It is not known whether this is due to capillary leakage, a mucosal defect, or both.

CORRESPONDENCE

REMOVAL OF PLASTER CASTS USED IN WALKING

To the Editor:—For years my colleagues and I have been removing plaster casts used in walking by cutting them laterally or anteriorly. Recently, I came to the conclusion that it would be much easier to cut a cast posteriorly over the calf of the leg. This is the softest spot of the leg, and there is no bone anywhere near. This way one does not have to make the cut curving around the foot but merely cuts the plaster from the top to the heel. After having done that, all that is necessary is to spread the cast just enough to allow the patient to slip his foot out backwards. I have not found that method described in the literature and thought it might be of some help to others, as it was to me.

CLONIC CONVULSIONS

To the Editor:—In the case report on "Clonic Convulsions After the Oral Use of Perphenazine (Trilafon)" in The Journal (169:834-835 [Feb. 21] 1959), the authors suggest that the patient had an epileptiform seizure. From the case summary it is noted that jaw and neck tremors were observed first, followed by generalized, clonic convulsions without loss of consciousness, opisthotonus, and rolling of the eyes upward. This description is reminiscent of the group of dyskinetic reactions of the extrapyramidal syndrome. Coming on shortly after the administration of perphenazine and characterized by tremors of the head and neck, hyperextension of the trunk, oculogyric crises, and generalized muscle spasms, it seems to be a striopallidal disorder rather than epilepsy.

These bizarre and sometimes frightening myoneural disturbances occasionally occur after the use of even small amounts of phenothiazines with a piperazine ring in the side chain and have been mistaken for epilepsy, encephalitis, and tetany. It would be rare for a generalized epileptic convulsion to occur without concomitant loss of consciousness. Freyhan recommends intravenously given caffeine and sodium benzoate, or phenobarbital sodium, during the acute phase. In addition, an anti-Parkinsonian agent should be given. When it is necessary to continue use of the drug, temporary reduction of dosage along with continued use of the anti-Parkinsonian compound is a relatively safe procedure. Apparently, physiological tolerance occurs and the dyskinetic syndrome is rarely seen after one week of phenothiazine therapy. Although this group of drugs may decrease the seizure threshold, this effect is considered a high dosage phenomenon. Epileptic convulsions would not be expected to occur on the first day of therapy.

"LABORATORY ERROR"

To the Editor.—In the Feb. 7 issue of The Journal, page 653, the reviewer of the book "Electrolyte Changes in Surgery" compliments the authors on their statement "that the most common electrolyte abnormality encountered in clinical medicine is the 'laboratory error.' " Excellent methods are now available for maintaining quality control in clinical laboratories.

As a clinical pathologist, I have reviewed more than 2,000 complete electrolyte studies (determination of pH; carbon dioxide content; concentration of sodium, potassium, chlorides, and total proteins; and the hematocrit reading) during the past two and one-half years. This review showed that the most common electrolyte abnormality encountered in our clinical practice was that due to patient disease. The second most common electrolyte abnormality was that due to therapeutic excess or neglect.

With proper use of control serum samples, the probability of "laboratory error" in any electrolyte determination can be statistically quantitated and kept below a predetermined level. The probability of error within a certain range of values can readily be kept below 1 in 1,000. This easily attainable probable incidence of error is certainly far removed from a level that would make "laboratory error" the most common cause of electrolyte disturbances.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Privileged Communications: Admissibility of Hospital Record Made by Attending Physician.—This was an action for damages suffered by the plaintiff as a result of an automobile accident. From a judgment for the plaintiff, the defendant appealed to the Supreme Court of Iowa.

Among other things the defendant contended that the trial court erred in refusing to admit in evidence the medical record of the plaintiff made at the hospital where he was taken immediately after the accident. The record was made in the handwriting of the attending physician, who also testified that he examined and prescribed for the plaintiff. The record was denied admittance in evidence on the ground that it constituted a privileged communication.

The Iowa law relative to privileged communications provides that: "No practicing attorney, counselor, physician, surgeon, or the stenographer or confidential clerk of any such person, who obtains such information by reason of his employment . . . shall be allowed, in giving testimony, to disclose any confidential communication properly entrusted to him in his professional capacity, . . ." The plaintiff contended that the record clerk of the hospital is the stenographer or confidential clerk of the attending physician and that the records in her charge taken in a professional capacity, or information gained while acting in such a capacity, are privileged.

We think there is much merit in this contention, said the Supreme Court. We have previously announced the rule that we will draw no fine lines as to whether a communication, professionally secured, is necessary or unnecessary. The policy of the statute is to provide for great freedom of disclosure by a patient to his physician, for the patient is often in no position to know what disclosures may or may not be necessary for his proper treatment. We have also held that the statute should receive a liberal construction designed to carry out its manifest purpose to make consultation by a patient with his physician entirely confidential and free from anticipation or fear that this confidence will be broken by the examination of the physician, directly or indirectly, as a witness in some legal proceeding. Clearly, then, such a statute is intended to cover any information gathered from the patient and placed in a record by an attending, consulting, or treating physician, whether done intentionally, willfully, or under a law requiring its preservation. It is our conclusion that any such information placed upon such hospital records would be, and is, covered under the statute as privileged to the same extent that the knowledge and information of the examining or treating physician is privileged.

The defendant also contended that the attending physician should have been permitted to answer questions as to whether or not the plaintiff, when seen in the hospital, was a drug addict; whether or not the plaintiff gave a history of drug addiction; and whether or not examination of the plaintiff indicated him to be a drug addict. Answers to these questions were not permitted on the ground that they were privileged, but the defendant contended that the observations inquired of and made by the doctor were of the nature of a casual observation and that he could make that determination without the confidence or any confidential relationship with the plaintiff.

There can be no serious contention, said the Supreme Court, that a professional physician-patient relationship was not established or intended to be established when the information and observation which was solicited by these questions was secured by the doctor. It may well be that this doctor or any doctor could identify a person addicted to the drug habit if he saw him on the street, but such is not the case before us. The information imparted, or which could have been imparted, certainly had, or could have had, a definite relation to his treatment, or possible treatment, and was not in the class of information willingly imparted as to matters foreign to the professional service anticipated, such as how or where the accident happened. The information sought was obtained during the professional relationship between the doctor and the plaintiff and was privileged.

The defendant's other contentions were also overruled and the judgment in favor of the plaintiff was affirmed. *Newman v. Blom,* 89 N. W. (2) 349 (Iowa, 1958).

Hospitals: Liability for Self-Inflicted Injury to Mentally Disturbed Patient.—This was an action for damages to a patient resulting from the alleged negligence of the employees of the defendant hospital. From a judgment in favor of the hospital the plaintiff appealed to the Supreme Court of Minnesota.

The plaintiff was hospitalized in the defendant hospital for the purpose of receiving care and treatment for injuries resulting from an automobile accident which occurred a few days prior to admission. No mention was then made of any mental disturbance or distress afflicting her. She was apprehensive and depressed for a few days, but about four days later she had progressed sufficiently to be able to go home. On the day she was to leave she was visited by a relative and a minister, and she seemed to enjoy talking to both of them. Shortly after the second visitor had left the plaintiff jumped out of the hospital window and sustained the injuries forming the basis for this suit.

At the trial the plaintiff called a specialist in psychiatry and neurology. His testimony, based on the hospital record that was read to him, was to the effect that it would be impossible for any nurse to recognize suicidal tendencies on the part of the plaintiff and that even as a psychiatrist he might not have noticed such tendencies. Another doctor called by the plaintiff stated that he had observed the plaintiff while she was in the hospital and had not noticed any unusual behavior on her part.

The defendant is a general hospital and has no ward or department nor any special equipment for the care of psychiatric or mental patients and does not accept such patients. On its staff it has several neurosurgeons and psychiatrists. It is the place where its staff doctors bring their patients for care, and the doctors, not the hospital, direct the care to be given such patients. The psychiatrists on its staff come in as consultants to other doctors but do not hospitalize their psychiatric patients there. If a patient manifested a mental disorder, the patient's doctor would immediately be advised to such effect, and the hospital would arrange for the transfer of such a patient to some mental hospital. The defendant is not equipped with portable window bars or cages for the restraint of mental patients. There are no locks on the windows. If a patient manifests suicidal tendencies, a report to such effect would be made to the patient's doctor, and the hospital employees would carry out his instructions in the case. Under no circumstances would they attempt to restrain, tie up, or imprison any patient without an order to do so from the patient's doctor, except in extreme emergencies.

In this case, said the Supreme Court, there was nothing to indicate that the plaintiff was contemplating suicide. On March 31, while still apprehensive, she appeared able to control herself rationally and was cheerful about the prospect of returning home that day. She enjoyed talking to the minister who visited her that day and was reluctant to have him leave. She also manifested pleasure at the visit of her relative. To hold, the court continued, that under such circumstances the failure of the hospital attendants to apply restraints or to take other steps to restrict or confine her on their own responsibility constituted negligence would place too heavy and dangerous a burden on attendants employed by a general hospital. The Supreme Court concluded that in a case where a patient is admitted to a general hospital merely for the treatment of injuries sustained in an accident and nothing is said about any mental disorders afflicting such patients, and where, after such an incident as described here, the patient manifests such improvement as to eliminate any evidence of peculiarity or tendency to suicide and the hospital attendants abide by the orders of the patient's physician, it can scarcely be said that a fact in issue is present as to the hospital's negligence.

Accordingly the judgment in favor of the defendant hospital was affirmed. *Clements v. Swedish Hospital,* 89 N. W. (2) 162 (Minn., 1958).

Autopsies: Right of Non-M.D. to Give Opinion as to Cause of Death.—This was a prosecution for first-degree manslaughter. From a judgment of conviction, the defendant appealed to the court of appeals of Alabama.

The evidence showed that the autopsy on the body of the deceased had been performed by Mr. Sowell, a staff member of the State Department of Toxicology and Criminal Investigations. He held a bachelor of science degree in chemistry and additionally had studied bacteriology and human anatomy, pathology, physiology, and toxicology. He testified that he had performed approximately 500 autopsies during the time he had been employed by the department. He was not a physician, and the defendant contended that it was error to permit him to give his opinion testimony as to the cause of the deceased's death.

In view of Mr. Sowell's studies and experience, said the court, we think he was shown to be amply qualified to testify as an expert in this field.

For this and other reasons, the judgment of conviction was affirmed. *McMurtrey v. State,* 101 S. (2) 88 (Ala., 1957).

Charitable Hospitals: Immunity from Tort Liability.—This was an action for damages caused by the alleged negligence of the defendant hospital. From a judgment in favor of the defendant, the plaintiff appealed to the Supreme Court of Pennsylvania.

While she was a patient in the defendant hospital, the plaintiff's wife fell and fractured an ankle. The defendant raised as its defense that it was an eleemosynary institution and thus not liable for the torts of its agents and employees.

The immunity of an eleemosynary institution from tort liability, said the Supreme Court, has long been the established rule in Pennsylvania. The rationale of the rule lay in the bounden duty of a public charity as a trustee to apply its funds in furtherance of its beneficent purpose. The doctrine has been abandoned in England and in a number of American jurisdictions but the law on this subject is clear in this state. Charitable institutions are not subject to liability for tort.

Even though the rule of nonliability is judge-made it should not be abrogated otherwise than by a statute made to operate prospectively.

The court therefore refused to repudiate the rule of nonliability, and the judgment in favor of the defendant hospital was affirmed. *Knecht v. Saint Mary's Hospital,* 140 A (2) 30 (Pa., 1958).

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Effects of Sublingual Nitroglycerin on Pulmonary Arterial Pressure in Patients with Left Ventricular Failure. J. B. Johnson, A. Fairley and C. Carter. Ann. Int. Med. 50:34-42 (Jan.) 1959 [Lancaster, Pa.].

The authors studied with the aid of right heart catheterization the hemodynamic alterations produced by glyceryl trinitrate (nitroglycerin) administration in 9 men and 4 women, between the ages of 35 and 74 years, with left ventricular failure. Most of the patients had hypertensive heart disease. After control cardiac outputs and blood pressure measurements in the brachial and pulmonary arteries were made, glyceryl trinitrate in doses of 0.6 mg. was administered sublingually. Cardiac outputs and blood pressure measurements then were repeated at short intervals during the succeeding 30 minutes. In 9 of the 13 patients a reduction in pulmonary artery pressure was noted within 5 to 15 minutes after the administration of glyceryl trinitrate. By the end of 30 minutes a reduction in pulmonary artery pressure was observed in all 13 patients. In 4 patients in whom it was possible to measure the pulmonary wedge pressure according to Hellem's method, a significant fall in this pressure was also observed. In 12 patients the total pulmonary resistance fell promptly during the first 15 minutes after glyceryl trinitrate therapy. There was no consistent alterations in the cardiac output, nor was there a significant increase in heart rate.

One patient with a clinical diagnosis of angina pectoris was catheterized as a part of a preoperative study in preparation for pericardial poudrage. A typical attack of anginal pain with radiation into the left arm, similar to the patient's well-documented previous attacks, occurred during the period of control hemodynamic observations which preceded the sublingual administration of glyceryl trinitrate. During the height of precordial pain there was a sharp increase in the pulmonary artery pressure, and the pulmonary resistance was greatly elevated. Administration of glyceryl trinitrate resulted in a prompt reduction of pulmonary artery pressure and total pulmonary resistance, and there was complete disappearance of anginal pain. The patient had no subsequent complications as a result of this experience. The clinical and physiological data obtained in this and other patients in this series after the administration of glyceryl trinitrate suggest that this drug has an important place in the management of patients with pulmonary artery hypertension and paroxysmal dyspnea associated with failure of the left ventricle.

Miliary and Meningeal Tuberculosis: A Review of 354 Cases. L. V. Reilly. Ulster M. J. 27:146-157 (Nov.) 1958 [Belfast, Northern Ireland].

Three hundred fifty-four patients were treated in the Whiteabbey Hospital, of the Northern Ireland Tuberculosis Authority, from late in 1947, when streptomycin first became available, to the end of 1956. The group included 76 patients with miliary disease alone, 160 with meningeal disease in whom miliary spread was not detected, and 118 with miliary and meningeal disease combined. The incidence of miliary and meningeal tuberculosis was highest in children under 4 years of age; these numbered 120. Sixty per cent of the adults were between 20 and 30 years of age. Five patients were over 60. A history of contact with a patient who had infectious tuberculosis was obtained in many patients, particularly in children.

The diagnosis of miliary tuberculosis was usually confirmed by roentgenologic evidence and by the detection of choroidal tubercles. These tubercles were found in 25 patients with only miliary disease, in 59 with combined miliary and meningeal disease, and in 8 with meningeal disease. Sometimes they were not found till some weeks after the diagnosis had been made. The Mantoux reaction was almost invariably positive. Bacteriological confirmation of miliary disease was usually obtained by the finding of Mycobacterium tuberculosis in the fasting gastric residue. Positive cultures were found in 49 of the 76 patients with miliary tuberculosis. A few attempts were made to isolate the organism from blood or bone marrow, but without success. Confirmation of meningeal disease was obtained by examination of the cerebrospinal fluid. The combination of increase in the protein content and in cell count with reduction in the sugar content of the cerebrospinal fluid was the usual finding. Cell counts varied widely from 60 to 300, and lympho-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

cytes usually predominated. Examination of the cerebrospinal fluid for tubercle bacilli was carried out in all cases, and tubercle bacilli were isolated in 144 of 160 meningeal cases, in 110 of 118 combined miliary and meningeal cases, and in none of the miliary cases. In addition to direct smear examinations, cultures were made.

Methods of treatment changed. At first the routine treatment consisted of the intramuscular injection of streptomycin, and intrathecal administration was added when meningitis was present. During 1949 aminosalicylic acid was added to the treatment routine, and isoniazid came into use toward the end of 1952. Improvement in recovery rate, reduction in length of illness, and a lower incidence of complications became evident after the introduction of isoniazid. The addition of isoniazid to the treatment made it possible to dispense with the intrathecal use of streptomycin in many patients. A group of 37 patients treated with the 3 substances without intrathecal therapy made a full recovery. The most serious complication of meningitis was severe mental retardation, usually with blindness and deafness. Eleven of 178 patients with meningitis had this complication, and some of them still survive. Early diagnosis offers the best hope of recovery. A marked reduction in incidence of the disease occurred in the last few years.

Sickle Cell-Hemoglobin D Disease. E. W. Smith and C. L. Conley. Ann. Int. Med. **50**:94-105 (Jan.) 1959 [Lancaster, Pa.].

The authors report a youth with sickle-cell–hemoglobin D (S-D) disease, who was followed up from the age of 14 months to that of 21 years. The patient had fair skin, blue eyes, blond hair, and sthenic habitus, and he had no features suggestive of Negroid ancestry. He had had recurrent episodes of severe pain in the back and extremities dating from early infancy, and many attacks of "pneumonia," transient ulcers of the lower legs, and a chronic hemolytic anemia. Nevertheless, he maintained the general appearance of good health and was an accomplished athlete. Examination of a fixed blood smear revealed pronounced anisocytosis, with a large number of target cells and a few sickle cells, and the electrophoretic pattern of the hemoglobin on filter paper at pH 8.6 could not be distinguished from that of sickle-cell anemia. Despite these findings a diagnosis of homozygous sickle-cell disease was questioned because of many atypical features. Additional studies were performed, which revealed clear separation of the S and D hemoglobin components on agar plates at pH 6.2, and a smaller component with the mobility of fatal hemoglobin was also observed. The mother of the patient and 5 of her relatives were found to have the hemoglobin D trait. The patient's father and 6 of his relatives had the sickle-cell trait. In neither lineage was there evidence of Negro ancestry. Since the patient's paternal grandfather married twice and S hemoglobin appeared in children of each marriage, it is almost certain that he carried the S gene. The atypical hemolytic disorder in the patient thus had resulted from the inheritance of hemoglobin D from the mother and hemoglobin S from the father. The genetic data which were obtained support the belief that hemoglobin D is an allele of types A, C, and S of hemoglobin.

Salt Metabolism in Hypertension. J. M. Weller and S. W. Hoobler. Ann. Int. Med. **50**:106-114 (Jan.) 1959 [Lancaster, Pa.].

It is an established fact that sodium chloride metabolism is abnormal in patients with essential hypertension. These patients may have a slightly elevated serum sodium concentration, expanded total body sodium content, and increased amounts of sodium and water in their arterial walls. Hypertension may be alleviated by sodium depletion. The authors' studies carried out at the University Hospital in Ann Arbor, Mich., confirmed the fact that chlorothiazide, a potent natruretic agent, may exert an antihypertensive effect in both hypertensive animals and in patients. This drug potentiates the effect of various antihypertensive regimens. The concomitant administration of chlorothiazide reduces the requirement for ganglionic blocking agents in the treatment of hypertension. Patients who have undergone sympathectomy appear to be unusually responsive to the lowering effect of chlorothiazide on the blood pressure.

The increased renal tubular rejection of sodium, chloride, and water in response to salt loading, which is present in patients with essential hypertension, is felt to be the result of the elevated blood pressure and not its cause. There is no evidence that water excretion, occurring in excess of sodium excretion, causes a "relative retention" of sodium in most of the patients with hypertension. The concept is discussed that in essential hypertension the sodium content of certain compartments or tissues, possibly including vascular smooth muscle, may be increased. This may lead to the rise in blood pressure. The effectiveness of chlorothiazide in the treatment of some patients with hypertension may be through its ability to deplete these tissues of sodium; in other patients it appears to act through depletion of the plasma volume.

Cholesterol Metabolism: Clinical Aspects. H. Malmros. Nord. med. **61**:3-7 (Jan. 1) 1959 (In Swedish) [Stockholm].

In essential hypercholesterolemia (Müller's disease) the hereditary disturbance in cholesterol metabolism can lead to considerable deposits of cholesterol in various tissues. Particularly in the cases in which the serum cholesterol content is around

400 mg. % or more, Müller's disease may be suspected as the cause. Examination of the serum cholesterol in siblings and other relatives may reveal several cases of cholesterolemia in the family. Such investigations are of practical value from the prophylactic standpoint, as in patients with hypercholesterolemia on a hereditary basis there is special risk of heart infarction or other grave manifestations of arteriosclerosis setting in early. Hypercholesterolemia can appear secondarily in other diseases, such as hyperthyreosis, nephrosis, and poorly regulated diabetes. Here cholesterol deposits may occur in different tissues. This is also true in cholesterolemia seen in essential or secondary hyperlipemia. Cholesterol deposits can occur without increased serum cholesterol, as in Hand-Schüller-Christian disease. Most gallstones are made up chiefly of cholesterol. Not infrequently there is xanthelasma palpebrarum in women with gallstones. The level of serum cholesterol in these cases is often increased. From the clinical point of view the most important cholesterol deposits are those which appear as atheromatous plaques in the intima of the arteries in arteriosclerosis. During the last 2 or 3 years in the department of medicine at Lund, 30 patients with essential hypercholesterolemia were treated, most of them for over a year, with a diet containing no fat except corn oil. A definite fall in serum cholesterol was noted after a few weeks.

Sideropenia Problem Illuminated by Follow-Up of Patients with Hypochromic Anemia. I. Lindblom. Nord. med. 61:7-13 (Jan. 1) 1959 (In Swedish) [Stockholm].

Of 305 patients with sideropenia (25 men and 280 women) treated 20 years ago, 80 have died; one death was due to cancer of the esophagus. Of the 123 patients followed up, 117 of whom were women, 2 had developed cancer of the hypopharynx (at present healed), and 1 had developed sublingual cancer (operated on 5 years ago and cured). Because of membranes of the hypopharynx which seem to be relatively resistant to therapy, 20 patients have been regarded as especially predisposed to cancer; they have required after-control, possibly combined with biopsies of specimens from the mesopharynx and the nasopharynx, in order, if possible, that precancerous conditions may be revealed early. The frequency of other symptoms of sideropenia is higher here than in other patients, but the symptoms have responded in the same degree to treatment with iron. While no relation between sideropenia and dietary deficiency has been established, the possibility of deficient diet to some extent years ago and in occasional cases now is not excluded. Graver recurrence of sideropenic anemia depends on acute causes, particularly bleeding. Return to normochromia occurs only gradually with increasing age, probably as a sign of slow building up of the iron depot. The irreversibility of sideropenia symptoms is greater in the patients initially treated only for their anemia and in those discovered through family connections than in the patients accidentally discovered to have the disease. A similar clinical course in the 3 pairs of uniovular twins in the material further supports the hypothesis that a dominant gene transmits the tendency to insufficient absorption of iron, disclosed especially when large amounts of iron are lost through bleeding.

Pernicious anemia was found in 10.6% of all the patients followed up in the series, and in 26% of those with stationary achlorhydria. Clinical observations on the 117 women suggest that hereditary factors, marginal amounts of iron in the diet, and pathological bleeding are conditions to be considered. Particularly in adolescent girls these conditions seem likely to cause sideropenia, which will recur on slight extra demands on the iron deposits.

Familial Hypercholesterolemic Xanthomatosis and Hypothyreosis. J. Opstad. Nord. med. 61:15-17 (Jan. 1) 1959 (In Norwegian) [Stockholm].

A case of familial hypercholesterolemic xanthomatosis and myxedema in a man, aged 42 years, belonging to a family with familial hypercholesterolemia, was observed for a year. The serum cholesterol concentration varied during treatment with thyroxin. After a transient fall 3 months after the thyroid function had become normal, the concentration rose to values considerably higher than those before treatment. The phenomenon is believed to depend on the patient's abnormal cholesterol metabolism. The author had previously reported a case of familial hypercholesterolemic xanthomatosis combined with myxedema in which there was an initial fall in the serum cholesterol concentration after treatment; 3½ years later, however, the serum cholesterol level was 390 mg. %, although the patient was euthyroid and metabolism was normal. It appears that thyroxin treatment of patients with familial hypercholesterolemic xanthomatosis and myxedema does not result in long-range reduction of the serum cholesterol, but a fall in the serum concentration occurs early or late during treatment and is followed by a secondary increase of serum cholesterol.

Hypoglycemic Effects of 1-(p-Chlorobenzenesulfonyl)-3-n-Propylurea: Observations in Man. A. M. Tornow, M. R. Zinke, P. Greenberg and C. M. Leevy. Diabetes 8:1-6 (Jan.-Feb.) 1959 [New York].

The authors report on 33 patients with diabetes mellitus who were treated with *chlorpropamide* [1-(*p*-chlorobenzenesulfonyl)-3-n-propylurea] for periods varying from 6 weeks to 6 months. Of the 33 patients, 18, who were controlled on diet and tolbutamide, or less than 20 units of insulin, were considered to have mild diabetes; 7, requiring 20 to 60 units of insulin, were considered to have moderate diabetes; 5 with maintained hyperglycemia and glycosuria on 60 or more units of insulin were considered to have severe diabetes; and 3 with unpredictable fluctuation between hyperglycemia-glycosuria-ketonuria and insulin shock were considered to have brittle diabetes. Two of the 18 patients with mild diabetes, who were previously controlled on tolbutamide, were no longer responsive to this drug at the time chlorpropamide therapy was instituted. During the earlier part of the investigation, each of the patients was given 1 Gm. of chlorpropamide daily; subsequently the daily dose varied between 0.25 and 0.5 Gm. depending on its effectiveness.

Results showed that chlorpropamide is an effective hypoglycemic agent in patients with diabetes mellitus. Chlorpropamide exhibited only a slightly greater hypoglycemic effect than tolbutamide after single doses of 1 Gm. of these drugs, but it appeared to be significantly more potent when given in maintenance doses of 0.5 to 1 Gm. daily. It permitted stabilization of diabetes in 2 patients who had become refractory to tolbutamide and in 4 patients with incomplete control on tolbutamide. There is, in general, an inverse relationship between the level of chlorpropamide and its effects on the concentration of sugar in the peripheral and hepatic venous blood. The drug tends to accumulate, so that adjustment of dosage is necessary to prevent profound drop in blood sugar. Severe hypoglycemia occurred in 3 patients on maintenance doses of 1 Gm. daily, associated with mental confusion, tachycardia, and sweating. Reduction of the administered amount and of the frequency of administration of the drug prevented recurrent hypoglycemia.

Chlorpropamide did not produce any evidence of dermal, renal, hepatic, or hemopoietic toxicity in the 33 patients. A regimen consisting of an initial dose of 0.5 Gm. of chlorpropamide each day, followed by a reduction or an increase depending on the clinical response, provided quickest control and fewest side-reactions. Slight gastrointestinal reactions were observed in 6 patients receiving 1 to 2 Gm. of the drug each day. Best control was established by periodic determinations of blood sugar and sulfonamide levels.

The Use of Latex Agglutination Reaction in the Diagnosis of Rheumatoid Arthritis. A. Ulloa, S. W. Griffin, M. L. Hayes and H. L. Holley. J. M. A. Alabama 28:212-214 (Jan.) 1959 [Montgomery].

The serum of patients with rheumatoid arthritis is capable of agglutinating sensitized particulate bodies, such as bacteria, erythrocytes, collodion, and latex particles. This agglutination capacity is predicted upon the presence in the serum from rheumatoid patients of factors that are either absent or present in minimal amounts in the serum of normal individuals. Such a factor has been identified in the gamma globulin component of rheumatoid serums with the use of the analytic ultracentrifuge, paper chromatography, and ion exchange chromatography, in addition to the variety of serologic indicator systems. The exact nature of this so-called rheumatoid factor remains obscure, but the fact that it appears consistently in the serum of rheumatoid patients and rarely in that of nonrheumatoid patients represents one of the most significant advances. Since Rose and coworkers in 1948 used sensitized sheep cells in the first serologic test for rheumatoid arthritis, many modifications have been suggested.

The authors report their experiences at University Hospital and Hillman Clinic in Birmingham, Ala., with the latex test in which whole serum is used. Tests were made on 171 persons, in 85 of whom the diagnosis of rheumatoid arthritis was definite, and in 9 probable. Twenty-three had osteoarthritis; 9, lupus erythematosus; 10, ankylosing spondylitis; and 5, gouty arthritis. The other groups included normal controls and patients with disorders other than rheumatoid arthritis. The test was positive in 75 of the 85 patients (88%) with known rheumatoid arthritis. The authors conclude that the latex test is a valuable aid in the diagnosis of rheumatoid arthritis.

SURGERY

Massive Systemic-Pulmonary Arterial Shunt Through Multiple Pleural Adhesions. P. T. De Camp and H. B. Hatch Jr. A. M. A. Arch. Surg. 78:206-211 (Feb.) 1959 [Chicago].

The authors report on a 34-year-old woman in whom a massive systemic-pulmonary arterial shunt occurred through multiple arterialized pleuropulmonary adhesions between the wall of the chest and the upper lobe of the left lung. This shunt increased the resting cardiac output by 75% and produced repeated attacks of choking and syncope. Preoperative roentgenograms of the chest revealed old fibrotic lesions in both lungs in the region of the lateral portions of the first and second anterior interspaces. A phonocardiogram recorded over the left third interspace near the sternal border showed a long systolic bruit with midsystolic accentuation. Division of the pleuropulmonary adhesions resulted in relief of all symptoms and eradicated the abnormal shunt.

Vascularized pleuropulmonary adhesions are commonly found at thoracotomy, and in some patients a pulsatile flow occurs from divided vessels. Vigorous pulsatile flow must indicate a systemic arterial communication, and the direction of the blood flow must be from the thoracic wall into the lung. The findings in this patient indicate that a considerable quantity of such blood may flow back into the pulmonary artery. A systolic, or continuous, murmur or souffle is characteristic, as is the roentgenographic evidence of notched adjacent ribs if intercostal arteries have sufficiently enlarged. The shunt may significantly increase the myocardial work load. If enough blood is deviated from the normal systemic pathways, syncope and other symptoms of cerebrovascular insufficiency may develop. Right heart catheterization may detect such a shunt, and is recommended in patients in whom this condition is suspected. In selected cases aortography may give additional information.

Surgical Treatment of Chronic Bilateral Disease of the Lungs. S. L. Libov and Z. I. Levina. Khirurgiya 35:13-19 (no. 1) 1959 (In Russian) [Moscow].

The possibilities of surgical treatment of certain bilateral diseases of the lungs are discussed. According to the literature and the authors' personal observations, bilateral disease of the lungs runs a severe course. In the series presented, 33 patients were examined; 27 of these patients suffered from bronchiectasis, and 26 were operated on. Bilateral operations were performed on 14 patients (single-stage operations were carried out in 3 instances). The greatest number of removed segments was 12. The left lung and the medial lobe of the right were removed in one patient. The majority of the two-stage operations were carried out at an interval of 6 months. Three patients died, one after a single-stage operation. All operations were performed with the patients under intratracheal oxygen-ether anesthesia.

Surgical Considerations of Peripheral Arterial Aneurysms: Analysis of One Hundred Seven Cases. E. S. Crawford, M. E. DeBakey and D. A. Cooley. A. M. A. Arch. Surg. 78:226-238 (Feb.) 1959 [Chicago].

The authors report on 107 patients with peripheral arterial aneurysms, who were operated on in the surgical services of the Jefferson Davis, Veterans Administration, and Methodist hospitals in Houston, Texas, during the past 5 years. Of the 107 patients, the peripheral arterial aneurysms were caused by arteriosclerosis in 54 and by trauma in 37; poststenotic aneurysms of the subclavian artery, just distal to a constriction produced by the anterior scalenus muscles, occurred in 3 patients; aneurysms occurred in 7 peripheral homografts, employed in the treatment of patients with occlusive lesions of the femoral artery, 8 to 26 minutes after the operation; the causative factor in the development of false aneurysms occurring after peripheral arterial operations in 6 patients was a combination of infection, tension at the suture line, and fraying associated with the use of the Edwards-Tapp nylon tube. Of the 54 arteriosclerotic aneurysms, 30 were located in the popliteal artery, 23 in the femoral artery, and 1 at the bifurcation of the innominate artery. The relatively high incidence of multiple lesions in this group of peripheral arteriosclerotic aneurysms is evident from the fact that more than one aneurysm was present in 26 of the 54 patients. Of the 37 patients with traumatic aneurysms, the aneurysm resulted from a gunshot wound in 25 and from a stab wound in 12. The traumatic lesions were widely distributed, but in 29 patients (80%) the aneurysm involved an artery necessary for normal blood flow, such as the carotid, brachial, femoral, popliteal, or subclavian.

The clinical manifestations of the disease varied according to the type of lesion. The age of the patients with arteriosclerotic aneurysm ranged from 45 to 85 years; these patients were considerably older than the others and frequently had associated heart disease and hypertension. The presenting symptom in most of the patients, regardless of the type of lesion, was a pulsating mass. Thrombosis was present in a significant number of patients, and this complication was associated with arterial insufficiency in all patients. Rupture had occurred in 8 patients with arteriosclerotic aneurysms, and heart failure was present in 3 patients with arteriovenous fistulas. The lesion was localized to an operable segment of artery in all patients, and treatment was directed at both excision of the lesion and restoration of circulation. The aneurysms were excised in all patients, and restoration of circulation was possible by end-to-end suture of the involved segments in 45; 14 of the latter patients had arteriosclerotic, 29 had traumatic, and 2 had poststenotic aneurysms of the subclavian artery. The defect remaining after excision of the lesion in the other patients was of sufficient length to require an arterial substitute to restore peripheral circulation. Homografts, Dacron tubes, and the Edwards-Tapp tube were used for this purpose.

The results obtained in these patients were extremely gratifying, particularly when compared with the natural course of the disease. Normal circulation was restored in most of these patients. Amputation was required in only 6 patients, although a large number had arterial insufficiency and gangrene at the time of the operation. Death occurred in only 3 patients in this series, all of whom had arteriosclerotic aneurysms, despite the high incidence of associated heart disease and hypertension. Of the 3 patients who died, death resulted from myocardial infarction in 2 who were operated on for rupture of the aneurysm, and death resulted from air embolism in the third patient. Although the follow-up period has been over 3½ years in most patients, the results have been well maintained. Three patients with arteriosclerotic aneurysm have died since operation, 1 of a ruptured aortic aneurysm, 1 of myocardial infarction, and 1 of cancer. Arterial occlusion has occurred in only 3 patients, and amputation has not been required by any of the patients since discharge from the hospital.

Arteriovenous Aneurysm of the Lung. D. K. Ossipov. Khirurgiya 35:8-13 (no. 1) 1959 (In Russian) [Moscow].

The author emphasizes that up to 1942 only a few reports were to be found in the literature regarding arteriovenous aneurysms of the lung revealed at autopsy. The signs and symptoms of these aneurysms are cyanosis, changes in the terminal phalanges of the fingers, and increase in the number of erythrocytes in the blood and of the hemoglobin percentage. These signs and symptoms may be very mild or may be entirely absent. The roentgenologic method of examination with tomograms, roentgenokymograms, and especially angiopneumograms is decisive in the diagnosis. Surgery is the only rational method of treatment. The most sparing resection of the lung is recommended. The author presents the case histories of 2 women on whom lobectomy was performed in connection with arteriovenous aneurysms of the lung. One patient was operated on under local anesthesia, and the other under intratrachael oxygen–ether anesthesia.

Idiopathic Mediastinal Fibrosis. N. R. Barrett. Brit. J. Surg. 46:207-218 (Nov.) 1958 [Bristol, England].

The author points out that, while some observers accept mediastinal fibrosis as the expected end-result of tuberculous mediastinal adenitis, syphilis, radiotherapy, or some comparable process, he argues that there is an idiopathic form which differs from fibrosis known to have been caused by chronic granulomatous conditions. He uses the term "idiopathic mediastinal fibrosis" because the etiology is unknown, because the site of the changes is the mediastinum above the heart, and because an abnormal proliferation of fibrous tissue is the visible anomaly. The clinical hallmark is the presence of venous hypertension in the catchment area of the superior vena cava. This hypertension is due to a fibrous mass that engulfs, invades, and destroys some or all of the great veins uniting to form the superior vena cava. The disease is rare, but it afflicts people of all ages and of both sexes; in general, the onset occurs in middle or late life.

As a rule, the symptoms of idiopathic mediastinal fibrosis appear suddenly in a patient who has previously been healthy. At the beginning, superior caval obstruction is neither suggested nor obvious in many cases. The first symptoms are often intermittent and, being relatively mild, may pass unheeded. In a typical case, the first symptom is puffiness of the face and arms, noticed especially when the patient gets up in the morning. In the second clinical phase, when the effects of superior caval obstruction are at their height, the following signs are added: a dusky color of the face, neck, and arms, with suffusion of the conjunctiva and perhaps telangiectasis; dyspnea, giddiness, tinnitus, headache, epistaxis, or hemoptysis; a feeling of pressure in the head; and a dislike of crowded places. All these unpleasant features are aggravated by coughing, straining, stooping, or exercise. After about 6 to 9 months the patient enters upon the third phase in which, as the years pass, there is a progressive relief of many signs and symptoms, but he never again becomes totally free from disability. The patient usually remains ambulant.

It is suggested that the pathological changes of idiopathic mediastinal fibrosis are akin to those found in periureteric fibrosis, pseudotomor of the orbit, and possibly ligneous thyroiditis (Riedel's disease). Idiopathic mediastinal fibrosis is a self-limiting disease, in which the signs and symptoms of superior caval obstruction are replaced and mitigated by those associated with the growth of a collateral venous circulation. The disease seldom kills; it is compatible with a long life, although the individual's working capacity may be somewhat restricted. There is no medical treatment. Irradiation is of no avail, and surgical operations have proved to be almost uniformly unsuccessful. The failure of bypass and replacement grafts is due to thrombosis in the grafts, and at the moment it seems to be impossible to prevent this.

Defects of the Interventricular Septum in Infancy: A Two-Stage Approach to Their Surgical Correction. H. D. Sirak, D. M. Hosier and H. W. Clatworthy, Jr. New England J. Med. 260:147-151 (Jan. 22) 1959 [Boston].

The high mortality of open-heart surgery for defects of the interventricular septum in infants may be avoided by a two-stage approach. Surgical treatment is urgently needed in many of these small patients, weighing less than 4.5 kg. (10 lb.), because of heart failure or recurrent respiratory infections that do not respond satisfactorily to medical therapy. A two-stage approach is proposed to increase both the immediate and the ultimate salvage rate in these patients and still avoid the high mortality of open-heart surgery in infancy. In the first stage, which is performed in infancy, the pulmonary artery is narrowed by being encircled with a band of plastic cloth, similar to that in the method of Muller and Dammann. The constriction increases resistance to outflow from the right ventricle. This, in turn, reduces the left-to-right shunt across the septal defect. Thus, the work of the left ventricle is decreased, systemic circulation is improved, and the lung vasculature is spared. The second stage is the corrective open-heart repair. At this time the septal defect is closed, and the constriction is removed from the pulmonary artery. The operation is performed after the child has grown large enough to tolerate cardiac bypass.

A 3-month-old infant was hospitalized in July, 1955, because of recurrent heart failure and pneumonia. Fluoroscopy showed that the activity of the pulmonary arteries was markedly increased. The patient remained in the hospital where he had recurring bouts of heart failure and respiratory infection. When he finally improved, cardiac catheterization was undertaken. This showed a defect of the interventricular septum, with moderate pulmonary hypertension and a large left-to-right shunt. On Dec. 1 a pulmonary tuck was performed. After the patient returned home, growth and development progressed normally until 2 years of age, when the parents noted that he became somewhat bluish on exertion. During the next 6 months the cyanosis gradually became constant, and at 28 months of age he was readmitted. Open-heart surgery was performed on Jan. 15, 1958, and the child was discharged on the 12th postoperative day. Recatheterization 2 months later indicated a return to normal hemodynamics. The authors believe that this is the first patient in whom both stages of the two-stage approach to the surgical correction of defects of the interventricular septum were successfully completed. Success depends upon proper selection of patients and an adequate reduction of the pulmonary artery lumen during the first stage.

Bacterial Endocarditis After Surgery for Acquired Heart Disease: Report of Two Cases and Review of the Literature. F. G. Hoffman, S. L. Zimmerman, E. A. Bradley and B. Lapidus. New England J. Med. 260:152-158 (Jan. 22), 1959 [Boston].

The cases of 38 patients in whom bacterial endocarditis developed after cardiotomy for acquired heart disease were collected from the literature, and 2 new cases are described in detail. The ages of the patients ranged from 20 to 51 years. Mitral valve surgery, including commissurotomy and suturing, was performed on 23 patients, aortic valve surgery (which included commissurotomy and nylon ball) on 21, and combined aortic and mitral valve surgery on 4. Cardiotomy without commissurotomy was carried out on one patient. Inquiry into the type of prophylactic antibiotic treatment before hospitalization for cardiotomy revealed information for only 7 patients, but the authors feel that further investigation of this point might be helpful. Staphylococcus pyogenes var. aureus was the causative organism in 26 cases; 11 were coagulase-positive, and 15 were coagulase-negative. Of the 11 patients with coagulase-positive staphylococci, 6 are living, and 5 dead. Of the 15 patients with coagulase-negative organisms, 7 are living, and 8 dead. These figures suggest only that coagulase-negative strains predominate and carry a higher mortality.

An attempt was made to correlate the possible source of infection with the temporal relations of onset of bacterial endocarditis after cardiotomy. Evidence suggests an extracardiac source when bacterial endocarditis develops within the first 4 weeks after operation, whereas in patients in whom the disease develops later, it is usually difficult to demonstrate the source. Further studies on the healing process of the surgically traumatized valves appear indicated. The frequency of postcardiotomy bacterial endocarditis can only be estimated, but it appears to be well under 1%. In the series studied, treatment regimens varied greatly. Almost all patients received penicillin, but streptomycin, tetracyclines, and chloramphenicol were combined with about equal frequency, apparently depending on in vitro sensitivity. The absolute mortality rate seemed to be about 35%, the corrected mortality about 27%. Previous reports on staphylococcic endocarditis not related to heart surgery gave a mortality rate of about 50%. No definite correlation between valvular calcification and mortality could be determined.

The clinical picture of bacterial endocarditis after cardiotomy was atypical in this series and differed from the usual subacute bacterial endocarditis. Fever, often low-grade, and septicemia were the only consistent findings. Changing heart murmurs, pericarditis, splenomegaly, petechiae, and embolic phenomena occurred in only a few patients. The diagnosis proved difficult, but postcardiotomy endocarditis should be suspected in any patient with fever after cardiotomy in the absence of the usual signs of bacterial endocarditis.

NEUROLOGY & PSYCHIATRY

Five Year Report of the Cerebral Palsy Program at the Nebraska State Orthopedic Hospital. H. E. Mitchell and B. W. Drompp. Nebraska M. J. 44:3-10 (Jan.) 1959 [Lincoln].

The authors report on 275 patients who were accepted, examined, and treated as cerebral palsy patients between 1952 and 1957 at the cerebral palsy clinic sponsored by the State of Nebraska and located at the Nebraska Orthopedic Hospital in Lincoln. Of the 275 patients, 187 were between the ages of 1 and 3 years; the fact that between these ages it is obvious to the parents that the child is not following a normal pattern of development, due to the lack of ability to sit or walk properly, accounts for the greater incidence of referrals at this age. A far greater number should be referred at this time. There were only 14 patients, aged less than 1 year, and only 11 over 13 years of age. Two hundred three patients (74%) had the spastic type of cerebral palsy; 47 (16%), the athetoid type; 15 (6%), the mixed type; and 10 (4%) were ataxic. The disease was mild in 77 patients (38%), moderately severe in 137 (50%), and severe in 61 (22%). Quadriplegia was present in 167 patients (60%), right hemiplegia in 35 (13%), left hemiplegia in 30 (11%), paraplegia in 38 (14%), triplegia in 4 (1.7%), and monoplegia in 1 (0.3%). Thirty-four patients (12%) had an intelligence quotient of from zero to 50, 96 (33%) had an IQ of from 50 to 70, 132 (47%) had an IQ of from 70 to 100, and 24 (8%) had an IQ of over 100. The disease was suspected to be congenital in 54 (20%), caused by prematurity in 34 (12%), due to birth injury in 127 (46%), caused by meningitis and encephalitis in 33 (12%), and due to other causes in 27 (10%).

The treatment program consisted of a coordinated effort of physical training and rehabilitation, speech training, correction and improvement of hearing and visual disability, and educational opportunities. The physical training program consisted primarily of functional activities. In order to proceed from stage to stage of the training program, bracing may play a very important part. Although conservatism is the watchword in the treatment of cerebral palsy, the authors unhesitatingly recommend surgical treatment when it is indicated to combat contracture or to improve the function of an extremity. One hundred eighteen patients underwent one or more surgical procedures. Surgical treatment on the upper extremity was performed primarily to relieve pronation contractures of the forearm, and good results were obtained from simple pronator teres tenotomy. Surgical treatment to improve the function of the lower extremity was gratifying in many patients. Hamstring transfer according to Egger's technique combats knee flexion and also corrects much of the adduction and internal rotation deformity, if present; it is considered the method of choice for the relief of scissor gait. Of 40 patients subjected to such transfers, 38 obtained excellent or good results, and 2 fair results. Soleus neurectomy is prefered to gastrocnemius neurectomy for the treatment of persistent talipes equinus, and there will always be a number of cases in which lengthening of the achilles tendon will be the procedure of choice.

In this series operative stabilization of joints proved very useful. The end-results in 171 operations performed on both upper and lower extremities were satisfactory in all but 15 cases. Of 57 patients treated in the occupational therapy department specifically to improve hand function, only 4 showed exceptional improvement, 42 showed moderate improvement, and 11 showed little or no improvement. Of 58 patients treated by the speech therapist, 3 showed exceptional improvement, 26 showed moderate improvement, and 29 showed little or no improvement. The educational program of the patients was recently surveyed by a mail questionnaire. Of 116 patients who answered the questionnaire, 87 were of school age. Thirty-seven of the 87 patients were in a school grade comparable with age; the remainder were below grade level or were no longer in school. Three children graduated from high school, and 2 are now attending college.

GYNECOLOGY & OBSTETRICS

Carcinoma Cervix Uteri: An Increase in Five Year Survival Rate: From 20 to 55 Per Cent during Twenty Years. H. B. Hunt, L. S. McGoogan, R. A. Bunting and R. E. Waggener. Nebraska M. J. 44: 53-58 (Feb.) 1959 [Lincoln].

The authors studied the results of treatment in patients with carcinoma of the uterine cervix who were treated at the University of Nebraska Hospital in Omaha over a period of 20 years. Public education, earlier diagnosis, and more prompt and improved treatment contributed to the recent increase in the 5-year survival rate among patients with carcinoma of the uterine cervix. According to the Nebraska State Department of Health, the death rate from carcinoma of the uterine cervix declined from 11.5 per 100,000 population for the period 1944-1948 to 6.6 for the period 1954-1957. At the University of Nebraska Hospital the 5-year survival rate for all cases of carcinoma of the cervix increased from 20.5% in 1936 to 55.8% in 1952. The average time elapsing between the beginning of symptoms and first consulation during the period 1930-1937 was 11 or 12 months, as compared with 8 or 9 months for the period 1938-1947 and 7 or 8 months for the period 1948-1952. The interval between diagnosis and initiation of treatment has been reduced from 21 days during the period 1930-1937 to 10 days during the period 1948-1952.

All women past 40 should have a thorough pelvic examination annually. Cytological smears and biopsy are vitally important in the detection of carcinoma of the uterine cervix in its earliest stage. If cells of smears appear suggestive of or positive for cancer, a thorough evaluation of the entire cervical and uterine canal is indicated. Treatment should be individualized according to the patient's age and whether she wishes to bear children. In young women, extensixe conization of the cervix or trachelectomy, followed by frequent examinations with smears, is considered acceptable treatment. In older patients, total hysterectomy with removal of a rather wide cuff of vagina is recommended. If a major operation is contraindicated, roentgenologic treatment and radium irradiation would be the therapy of choice.

Of 111 patients with invasive carcinoma of the uterine cervix admitted to the University of Nebraska Hospital between 1948 and 1952, 102 were treated with radiotherapy alone, 5 with a combination of radiotherapy and surgery, and 4 with Wertheim's hysterectomy with radical lymph node dissection. Radiotherapy consisted of 2 or 3 applications of radium across the vaginal vault and along the uterine canal supplemented by external roentgenotherapy, delivered during a total period of 5 weeks. The survival rate among patients so treated was 54.7%. This is a great improvement over the survival rate of 20.5% for patients given intracavitary radium treatment alone during the period 1931-1936. The survival rate doubled to 41% during the period 1937-1947 when patients were referred earlier and received additionally external roentgenologic treatment. Improvement of radiotherapy was effected not through any increase in total dosage of radium or roentgen rays but through more individualization according to the distribution of disease, anatomy of the patient, and the general health and tolerance of the patient for irradiation.

There has been a recent revival of the surgical approach, and in the hands of the highly trained and technically skilled gynecologic surgeon the patient salvage for stage 1 carcinoma of the cervix is equal to that of the salvage with irradiation therapy. In stage 2 carcinoma of the cervix the survival rates after surgery are lower than those in stage 1; they are similar to those for irradiation therapy, but they are not greater. No proof has been presented that the superb operation of even the master surgeon excels or, in fact, equals contemporary radiotherapy of comparable excellence in the control of stage 1 and stage 2 cancer of the uterine cervix.

PEDIATRICS

Intestinal Polyposis with Oral Pigmentation (Peutz-Jeghers Syndrome): Report of a Case with Review. L. W. Falkinburg and M. N. Key. J. Pediat. 54:162-169 (Feb.) 1959 [St. Louis].

The authors report on a 5-year-old boy with intestinal polyposis and with abnormal pigmentation in and around the mouth. On admission to the Roger Williams General Hospital in Providence, R. I., the child complained of severe abdominal pain, nausea, and vomiting. Laparotomy was performed, and a large amount of clear serous fluid was found in the peritoneal cavity. In the mid-jejunum there was a large intussusception which was irreducible, and a mass interpreted as a polyp could be palpated inside. This segment of small intestine was resected, and an end-to-end anastomosis was performed. Examination of the operative specimen revealed a polypoid adenoma of the jejunum. The patient's recovery was uneventful, but 6 months later he was admitted to the hospital for a second time, complaining of abdominal pain, tarry stools, and repeated attacks of respiratory infections. On physical examination the boy was pale, and his lips were cyanotic. Numerous small blackish-purple, discrete spots were noted on the mucosal surface of the lower lip, on the mucosal surface of the cheek, and on the hard palate. Roentgenologic examination of the gastrointestinal tract showed evidence of jejunal polyposis. Three blood transfusions were given, and iron therapy was started. There was general improvement, and the patient was discharged 3 weeks later with a diagnosis of Peutz-Jeghers syndrome. The patient was readmitted to the hospital after 3 months because of severe abdominal pain, anorexia, nausea, and vomiting. Laparotomy was performed, and 2 jejunal polypoid adenomas were removed. Recovery was uneventful, and the patient was referred to the outpatient department for periodic observation.

Peutz-Jeghers syndrome is a combination of oral melanosis and small intestinal polyposis, in which frequently a definite hereditary factor can be demonstrated. In this patient the pigmentation was noticed and correctly interpreted only on the second hospital admission, after the patient had undergone, during a previous admission, a major operation for intestinal obstruction. Such pigmentation should be looked for in every case of small intestinal polyposis, and, conversely, the discovery of such areas of pigmentation in the course of physical examination should direct the attention of the physician to the gastrointestinal tract. The occurrence of polyps in the small intestine is sufficiently uncommon to arouse suspicion of the syndrome. The first concern in the treatment is usually the relief, by surgical removal, of the intussusception responsible for the acute intestinal attack. After the diagnosis has been established, the question arises as to whether polyps shown by roentgenograms should be removed electively. In considering elective polypectomy no general rule can be laid down, but each case must be carefully and individually evaluated. The anemia, which is the result of slow bleeding from the polyps, can be successfully treated by blood transfusions and the administration of appropriate iron compounds. No treatment has been suggested for the melanotic areas, which are asymptomatic in themselves and are not cosmetic problems.

BOOK REVIEWS

Psychotherapeutic Drugs. By Ashton L. Welsh, M.S., M.D., Assistant Professor of Dermatology and Syphilology, University of Cincinnati College of Medicine, Cincinnati, Ohio. Publication number 350, American Lecture Series, monograph in Bannerstone Division of American Lectures in Dermatology. Edited by Arthur C. Curtis, M.D., Chairman, Department of Dermatology and Syphilology, University of Michigan, Ann Arbor. Cloth. $4.75. Pp. 139. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

In a period of only five years tranquilizers have been produced and consumed at an alarming rate, probably exceeded in volume of total sales only by antibiotics and vitamins. A new language has been developed concurrently: ataraxic, normalizer, calmative, neuroleptic, psychic energizer, antiphobic, and phrenotropic are among the new terms constantly found in lay and medical literature. While in many instances these psychotherapeutic agents induce an improved mental state, they frequently produce undesirable subjective responses, toxic side-reactions, and objectionable effects when given with other drugs.

The principal groups of these drugs are the phenothiazines, the rauwolfia alkaloids and fractions, the substituted propanediols, the diphenylmethane derivatives, the ureides, and the amides. All of these categories contain drugs more familiar to practitioners under such popular names as Thorazine, Sparine, Compazine, Serpasil, Miltown, and Atarax. Each is listed in this useful book by generic as well as proprietary name, accompanied by details or its chemical formula, pharmacological action, administration and dosage, general and specific uses, toxic effects, and side-reactions. The listings are orderly and admirably arranged for quick reference. Specific dermatological uses, dermal reactions and allergic phenomena, cardiovascular complications, and side-effects on the central nervous system are stressed.

Many problems have arisen from the vast outpouring of tranquilizing drugs. When 30% of the prescriptions written in the United States contain one of these drugs, many physicians cannot be fully alert to the danger that artificially produced "peace of mind" may only drug mankind into hopeless inertia. The author is fully justified in his emphatic conclusion that "tranquilizing agents offer no substitute for accurate diagnosis or adequate medical supervision: they are adjuncts likely to displace, but never to replace some other forms of therapy." No physician should prescribe these drugs indiscriminately. This book, excellently produced, contains an extensive bibliography and an index.

A Textbook in Rorschach Test Diagnosis for Psychologists, Physicians and Teachers. By Ewald Bohm, Ph.D. Translated by Anne G. Beck, M.A., and Samuel J. Beck, Ph.D., Professorial Lecturer, University of Chicago, Chicago. Cloth. $7.75. Pp. 322. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1958.

The Rorschach test has become, over the years, the major instrument of clinical psychologists engaged in psychodiagnostics. This volume brings to the United States, in translation from the German, much of the foreign literature previously available only in that language. It is a careful presentation of the author's views on the use of the test. While the author chose to present a step-by-step manual, taking the reader through each minute stage of administration, scoring, and interpretation, the completed volume is far from being a beginner's textbook. This is a highly sophisticated and complex presentation which will be welcomed by the initiate, an adjunct to other reading for the novice, and quite beyond the uninitiated. The language of the book is largely made up of "Rorschach vernacular" presented from the particular bias of the author and the translators, who frequently draw direct causal relationships between pathological states and specific Rorschach signs. The theoretical framework in which the author chose to make his interpretations is admirably presented.

In certain areas the author shows a broad acquaintance with the differing viewpoints expressed in the literature and indicates the need for caution in interpreting these factors. His discussion of intelligence and the use of the Rorschach test to measure this highly controversial facet of the patient is clear and precise, yet here and elsewhere throughout the book there is an almost too ready acceptance of opinion favoring the Rorschach test without evaluating opposite opinion. For example, in his discussion of organic psychoses he seems to accept without question the quotation "It may be considered a proven fact that the senility process is a reversing of the development process." Observers in gerontology, at least in the United States, hold that this still needs to be proved.

In the area of psychopathology the author is more questioning and more evidently alert to the complexities within the field. Here, while expressing himself with an unalleviated dogmatism, his

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

presentation is logical, precise, and well reasoned. The book is unlikely to be read widely outside the field for which it was written because of the amount of complicated personality evaluation within it. In its field, however, and certainly among those who share the author's Rorschach orientation, the book should soon become a standard textbook and reference work. While the medical practitioner may find it generally too complex, many psychologists should find new and interesting facets of psychodiagnostics clarified for them. As a highly specialized book on a subject that needs constant elaboration this should become a part of most reference shelves on the Rorschach test.

Leukemia. By William Dameshek, M.D., Professor of Medicine, Tufts University School of Medicine, Boston, and Frederick Gunz, M.D., Ph.D., Hematologist, Christchurch Hospital, Christchurch, New Zealand. Cloth. $15.75. Pp. 420, with 143 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1958.

This excellent book is the first comprehensive treatise on leukemia published in the past 20 years. It covers the entire field in detail and with a comprehensive bibliography, with chapters on etiology, classification, prevalence, symptoms, special features, prognosis, and treatment. The strongest parts of the book are the sections on the clinical aspects of the disease, which are discussed in detail with emphasis on the great variability of the diseases; their differences at various stages; their complications, both common and unusual; and the problems of diagnosis and differential diagnosis, which often offer difficulties. The fact that the findings in leukemia are not static but endlessly changing, offering a constant diagnostic and therapeutic challenge, is stressed. The chapter on treatment is comprehensive. Not only are general indications and contraindications for the various agents given but detailed discussion accompanies the explanation of the use, method of administration, and limitations of each therapeutic agent. The type is large and clear, and the photographs of clinical material, roentgenograms, tissues, marrow, and blood are uniformly excellent; but the colored illustrations, unfortunately, are highly diagrammatic. There are many excellent charts summarizing clinical and other data. Two minor criticisms might be raised. The first is of the emphasis on the "myeloproliferative" disorders and the attempt of the authors to develop or expand a unified system based on morphologic rather than etiological or dynamic grounds; the second is of the somewhat chatty and informal tone which creeps in and seems, at times, out of place. Students should find the book handy for reference; hematologists, for a comprehensive summary; and all others whose practices bring them in contact with leukemia, for a practical guide.

A Compendium of Research and Theory on Stuttering. By Charles F. Diehl, Ph.D., Professor of Psychology, Director, Speech Center, University of Kentucky, Lexington. Publication number 344, American Lecture Series, monograph in Bannerstone Division of American Lectures in Otolaryngology. Edited by Norton Canfield, M.D. Cloth. $9.75. Pp. 314. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

The behavior complex called stuttering, whether it is a speech impediment, a psychological symptom, or a habit pattern, has received broad attention in both popular and scholarly literature. Books have been written expounding particular theories, detailing research, advising parents, elaborating self-cures, and explaining therapies for this condition. At times it appears that the reverse of Mark Twain's comments on the weather is true of stuttering. Everybody is not only talking about it but seemingly doing something about it, and yet like the weather it goes on and on. There seems to be the same number of stutterers (about 1% of the population) despite the work being done to alleviate the condition. This book reflects this widespread interest. It is truly, as the title implies, a compendium of research and theory. It was published because it was believed that a summary of what has been written in the field was needed. The book presents brief synopses, in an orderly fashion and almost without evaluation of either their worth or their importance, of what has been said, studied, discovered, and conjectured in print about stuttering. It offers no qualifications of the material, presenting for each study or theory the author's name, the title of his study, whether a research design was employed, what the study was about, and the conclusions reached. It is often unclear, in its conclusions, whether these are the findings of the researcher or whether they represent judgments made by the editor.

To any student of stuttering the book will save many hours of library study, but to anyone interested in self-help for stuttering it will provide only confusion, for no one approach is represented as being better than another. If widely read by stutterers the book may end by working a hardship on clinicians, for any reader will be impressed by the multiplicity of theories, the lack of agreement among researchers, and the comparative lack of acceptance within the field of any single approach. The book is easy to read and simply designed, and the research seems adequately summarized. Professional practitioners engaged in working with stutterers will undoubtedly want the book for their reference shelves, and speech therapists should find it useful in filling out the gaps in their own reading. The general medical practitioner, however, will find the book of little interest.

The Management of Fractures and Dislocations: An Atlas. Volumes I and II. By Anthony F. DePalma, M.D., Professor of Orthopedic Surgery, Jefferson Medical College, Philadelphia. Cloth. $35 per set of 2 volumes. Pp. 469; 471-960, with 1927 illustrations by Barbara B. Finneson and William A. Osburn. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

In this large atlas of fractures and their treatment the author has handled his subject well but not logically. With a little rearrangement all the fractures and dislocations of the upper extremities could have been placed in one volume, and those of the lower extremities in the other, but this was not done. This is not a serious criticism, because one would certainly buy both volumes in any case, and in spite of this the presentation of any fracture can be located easily. The book contains nearly 2,000 clear, distinct line drawings. Each drawing is accompanied by a brief description which would make the book of special value in the admitting department of a hospital. For some unaccountable reason, there is no description of the Leadbetter maneuvers for reduction of fractures of the neck of the femur. In the case of fractures of the ankle and leg there are no plates showing a pin or tongs in the os calcis to gain skeletal traction for the explosion type of fracture in the lower end of the tibia. Some rather terse comments, such as "don't abandon a pathological fracture" and "never use a tourniquet in open fractures," are especially commendable. Although all will not agree with the author's method, the book is easy reading and the illustrations are good.

Electrocardiography. By E. Grey Dimond, M.D. Director, Cardiovascular Laboratory, Professor of Medicine, University of Kansas Medical Center, Kansas City. Second edition. Cloth. Pp. 172, with illustrations. University of Kansas Medical Center, Rainbow Blvd. at 39th St., Kansas City 12, Kansas, 1958.

This book is especially designed for the beginner and is written in simple terms. The diagrams are also clear and so elementary that some readers might be annoyed at not being given credit for a higher level of intelligence, but the author, who has had many years of experience in teaching electrocardiography, has probably found that the average physician has forgotten even the most elementary principles of electrophysics. In a book of this sort the material must, for purposes of clarity, be presented in a dogmatic manner. In spite of this handicap the author has managed to give a remarkably accurate presentation of current concepts in electrocardiography in a practical manner. There are several references to other books on the subject. This is an ideal book for the general practitioner who is anxious to be introduced to electrocardiography.

A Symposium on the Evaluation of Drug Toxicity. Editors for Imperial Chemical Industries, Ltd. (Pharmaceuticals Division): A. L. Walpole, Ph.D., B.Sc., and A. Spinks, M.A., Ph.D., B.Sc. Cloth. $5.50. Pp. 138, with 58 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Place, London, W. 1, England, 1958.

This book presents the transcript of a symposium held at Alderley Park, Macclesfield, England, on Oct. 1, 1957, in conjunction with the opening of the new research laboratory of the Imperial Chemical Industries, Ltd. The skilled investigator, familiar with the methods of evaluation of drug toxicity, will find little of interest in this book, since most of the material appears to be somewhat elementary. The papers dealing with the discussion of the toxic action of drugs on the liver and on the bone marrow, by exception, become so involved that the average reader may find the text difficult. It is doubtful whether most readers of THE JOURNAL would care to add this book to their libraries.

Viral and Rickettsial Infections of Man. Edited by Thomas M. Rivers, M.D., and Frank L. Horsfall, Jr., M.D. Aided by grant from National Foundation. Third edition. Cloth. $8.50. Pp. 967, with 134 illustrations. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6; Pitman Medical Publishing Company, Ltd., 45 New Oxford St., London, W. C. 1, England, 1959.

The rapid growth and development of virology and rickettsiology amply justify the appearance of this new edition. It contains seven new chapters, and there are 14 new authors. The first 12 chapters are devoted to the more fundamental aspects of virology and rickettsiology and include discussions of the chemical and physical properties of viruses, the virus–host cell relation, interference, chemotherapy, the important techniques used in the propagation of viruses and Rickettsiae, the serologic reactions in viral and rickettsial infections, and the principles of epidemiology. In the rest of the book every important viral and rickettsial disease is considered in detail. The discussion of each infection includes something of its history, cause, symptoms, lesions, diagnosis, treatment, and control measures. The student, the clinician, and the investigator should find in this book all of the information available concerning viral and rickettsial diseases. If a particular technique or piece of information is not presented in detail, adequate references are usually provided at the end of each chapter. In spite of the fact that there are many contributors there is little if any reduplication of subject matter in the various sections. The editors hoped that this book would prove useful to physicians, teachers, and investigators, and this objective has been attained. No one who is interested in the general subject of viral and rickettsial diseases should fail to read this book.

QUESTIONS AND ANSWERS

CEREBRAL ARTERIOSCLEROSIS

To the Editor:—*Have any studies been made on the use of desoxyribonucleic acid or ribonucleic acid in the treatment of cerebral arteriosclerosis? Supposedly, some months ago, an article was published in the* American Journal of Psychiatry, *advocating its use.*

W. W. Brubaker, M.D., Annville, Pa.

Answer.—The correspondent apparently refers to a report by Cameron (*Am. J. Psychiat.* 114:943, 1958) in which the use of nucleic acid in aged patients with memory impairment is described. According to Cameron desoxyribonucleic acid and ribonucleic acid were given intravenously in doses of 100 to 500 mg. Ribonucleic acid was also given orally in daily doses of 10 to 20 Gm. In all 23 patients treated favorable results were noted. In one-half the results were good. The best results were obtained in those with severe memory deficits and marked confusion. Results were usually noted in four or five days. Intravenous injection appeared to be a better method than use of the oral route. Hyaluronidase was given intrathecally to some patients. It is hoped that effective and simple treatment will be available for aged patients with memory impairment, presumably so-called senile dementia or chronic brain syndrome. The report referred to is a preliminary one and lacks specific details in all of its aspects. Control data are wanting. Further study will be needed before this treatment can be routinely recommended.

STAPHYLOCOCCIC INFECTIONS

To the Editor:—*Would it be advisable to withhold one, or possibly two, antibiotics in a hospital of 200 beds to prevent severe staphylococcic infections? Should a surgeon with known active furuncles of such exposed portions as the face, neck, or hands, or one who is a carrier of staphylococci, be allowed to enter the operating room?*

M.D., Wisconsin.

Answer.—Many consider it advisable to withhold one or two antibiotics from general use. Erythromycin and oleandomycin are two that one staphylococcic infection committee recommended holding in reserve for use in proved resistant staphylococcic infections. Penicillin, streptomycin, tetracycline, chloramphenicol, and novobiocin are prescribed as indicated. Another group might feel it wise to withhold a different collection from general use. In most hospitals any person with obvious active furuncles is denied access to the operating suite. The question of staphylococcic carriers is a difficult one. One may have negative cultures one day and positive the next. Careful technique with adequate masks and frequent changes would seem the best answer.

MYELOGRAPHY AND DISKOGRAPHY

To the Editor:—*What risks are associated with myelography and diskography? Is a surgeon justified in obtaining a myelogram or diskogram to establish evidence of disease for medicolegal reasons, or are these procedures justified only to establish additional clinical evidence when symptoms are severe enough to demand surgery?*

William L. Minear, M.D.
Albuquerque, N. Mex.

Answer.—The risk of myelography consists primarily in the development of adhesive arachnoiditis after retention of the contrast medium. The degree of such arachnoiditis depends, to some extent, on how much contrast material is left in the spinal canal after the injection. Iodized oil tends to remain indefinitely in the dural sac, whereas iophendylate is absorbed gradually over a period of months or years. If the patient has leaned forward long enough, so that the contrast medium has flowed into the cranial cavity, the cranial subarachnoid spaces may be affected. There is some evidence that blood tends to emulsify the iodized oil and may add to the likelihood of producing arachnoiditis. Arachnoiditis may occur without myelography or surgery. Patients involved in litigation have symptoms ascribed to retained contrast medium more frequently than others. Arachnoiditis and radiculitis have not been reported after diskography. At least two cases of infection of the intervertebral disk have been described, in a few thousand diskograms.

In the case of a suspected intraspinal protrusion of an intervertebral disk, the diagnosis and indications for operation are usually primarily determined clinically. Myelography is generally indicated as a preoperative measure to confirm the clinical impression, to make a more exact localization, to seek the presence of multiple disks, and to exclude other conditions, such as neoplasm. Diskography has not

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

been widely accepted, and some of its early proponents have abandoned the procedure. This consultant agrees with the proponents of diskography that, after negative findings in the myelogram, diskography is to be preferred to a direct exploration, so that no operation is performed if the diskography shows normal findings. On the other hand, it would be of interest to know the frequency of derangement of an intravertebral disk in asymptomatic persons. When a myelogram, or diskogram, is recommended for medicolegal reasons only, the surgeon should emphasize the risks of the procedure and leave the decision to the patient. If the patient decides to request the procedure anyway, some surgeons refuse to carry it out for these reasons only but others may properly do so.

MEDICOLEGAL QUESTIONS

To the Editor:—*From the medicolegal point of view, is there any evidence that trauma or any extraneous cause may produce cancer, sarcoma, or leukemia or congenital, endocrine, or metabolic disease? In one case, a woman received a blow on the left breast in an automobile accident and within a year carcinoma of the left breast developed. In another patient, after contusion of the tibia a Ewing sarcoma developed in that bone. In an x-ray technician who developed leukemia, could overexposure to x-rays during the course of employment have been a causative factor? A pregnant woman was exposed to carbon monoxide fumes from a defective furnace, and her child was born with a cleft palate and intestinal abnormalities, requiring colostomy. Three siblings were normal, and there was no history of this condition in other members of the family. Did the carbon monoxide poisoning contribute to the development of these deformities? After an automobile accident in which there was severe emotional strain, a patient developed diabetes. Was the accident a precipitating cause of the diabetes? Another patient developed rheumatoid arthritis after a similar experience. Did the accident contribute to the development of the rheumatoid arthritis?*

William L. Minear, M.D.
Albuquerque, N. Mex.

Answer.—There is no evidence that a single episode of trauma ever produces cancer. There are cases reported in which repeated trauma seems to have played a role, and several reports have implicated exposure to x-ray therapy as a cause of leukemia and carcinoma of the thyroid gland. There are several hundred known carcinogens which can be extraneous causes of cancer. It would be difficult to relate carbon monoxide poisoning and congenital deformities or emotional strain and diabetes or rheumatoid arthritis.

HAZARDS OF SNUFF AND CHEWING TOBACCO

To the Editor:—*What are the possible harmful effects of the use of snuff and of chewing tobacco?* *M.D., Virginia.*

Answer.—Dygert (*New England J. Med.* 257:311, 1957) showed that snuff may be a source of the pathogens Pseudomonas aeruginosa and Proteus vulgaris. He reported a case of bronchitis in which the clinical and cultural findings showed that these organisms were pathogenically active. When the use of snuff was discontinued, the pathogens disappeared from the sputum. After a few weeks these organisms reappeared in the sputum, and the patient admitted that he had been chewing cut plug tobacco. When he stopped chewing tobacco, the organisms disappeared again.

Chinachoti and Tangchai (*Dis. Chest* 32:687, 1957) reported pulmonary alveolar microlithiasis in a patient who had been a heavy user of snuff for 23 years. They expressed the view that the pulmonary lesions found at autopsy were associated with the inhalation of snuff, which is composed of tobacco and earthy material. The low content of silica and the nature of the pulmonary lesions excluded silicosis.

The results of chewing tobacco are not well defined. One explanation is that the nicotine in smoke is in a more finely divided state than it is in tobacco juice derived from chewing tobacco and thus it is absorbed more easily from smoke than from tobacco juice through the oral mucosa; therefore, the concentration in the blood, derived from tobacco juice, may be less. Biebl and co-workers (*Am. J. Physiol.* 100:167, 1932) reported that when nicotine is absorbed from the gastrointestinal tract, it is detoxified by the liver before it reaches the general circulation.

SHOULDER-ARM SYNDROME

To the Editor:—*After an acute coronary occlusion which seems to have healed well, a patient had no sequelae except severe left shoulder and arm syndrome which failed to respond to treatment. X-ray therapy, cortisone injections, methylprednisolone (Medrol), vitamin B complex, dextropropoxyphene hydrochloride (Darvon) compound, salicylates, aspirin, and vitamin* B_{12} *were tried without benefit. How long may this shoulder-arm syndrome be expected to last, what is its cause, and is there any other treatment which might give relief?* *M.D., New Jersey.*

Answer.—The pain fibers from the fourth cervical segment to the second thoracic segment overlap in producing painful arm and shoulder syndromes in connection with cardiac pain of a referred type. Because of this, many patients with coronary insufficiency, angina pectoris, and myocardial infarction have referred pain in the left shoulder. This pain tends to limit the motion of the left shoulder. The fixation of the shoulder and lack of motion produce a synovitis of the joint which further restricts shoulder motion. This, in turn, produces an atrophy of disuse, particularly of the deltoid muscle. The patient suffering from any of the above-mentioned conditions should keep his hands above his head for 10 or 15 minutes four or five times daily. Those who do this seem to have no trouble with the so-called cardiac arthropathies. Free extension of the shoulder in the lateral and perpendicular positions will free these adhesions. Sometimes this must be done with the patient under anesthesia to produce full abduction. Maintenance of this free position plus regular exercise usually results in a normally functioning shoulder. Incidentally, it has often required more time to cure these arthropathies than the myocardial infarction.

IDIOPATHIC HYPOGLYCEMIA

To THE EDITOR:—*Are there any ill-effects from a continued low-carbohydrate diet containing 100 to 150 Gm. of protein per day in a patient with idiopathic hypoglycemia? Would it be likely to cause an osteoarthritis or aggravate a preexisting one?* *M.D., California.*

ANSWER.—In a healthy person wide ranges in dietary composition are tolerated with no apparent ill-effects. A diet low in carbohydrate and with 150 Gm. of protein should not cause or aggravate osteoarthritis. The low-carbohydrate high-protein diet designed to render a steady support to blood sugar by gluconeogenesis, rather than sudden rises as with carbohydrate, has enjoyed a vogue in the treatment of functional hypoglycemia, but while this was an interesting concept, such treatment frequently failed. The most popular current concept is that functional hypoglycemia is a psychosomatic disorder and that it frequently responds to a sympathetic ear and reassurance. Osteoarthritis to date has been linked with trauma and the aging process. Its cause and pathogenesis are unknown. There is no evidence that it is related to carbohydrate metabolism or changes in the diet. This statement does not apply to such other forms of arthritis as gout.

ORTHOPEDIC TESTS

To THE EDITOR:—*Please explain the following orthopedic tests: (1) Nachlas, (2) Yeoman, (3) Lasègue, and (4) Viets.* *M.D., Louisiana.*

ANSWER.—In the Nachlas test the patient is placed prone on a hard table and the knee is flexed by the examiner. If the result is positive, the patient has pain in the sacroiliac joint, lumbosacral joints, and down the anterior and posterior aspects of the thigh and calf. The rectus femoris tightens up and extends the pelvis and spine, thus causing pain, if there is a lesion in the sacroiliac or lumbosacral area.

The Yeoman sign is not a test but a sign. Yeoman stated that arthritis of the sacroiliac joint caused sciatic pain in 36 of 100 patients with sciatica so that it actually would be determined by reading the roentgenograms. The symptoms are caused by a periarthritis of the anterior ligaments of the sacrum, the piriformis muscle, and radicals of the sciatic nerve.

The Lasègue test consists of reproducing the pain when the patient is flat on his back with the leg flexed and knee extended. It was described as a test for muscle spasm in the hamstring muscles. All three of these tests were described before the exact lesion being tested for was known, and varied explanations of the cause of the positive test were postulated, all of which were wrong. They are interesting historically but of questionable practical value if their original interpretations are to be held.

The Viets test is another example of the absurdity of using eponyms for tests. It is a test known by its practical value but not by this name. It is the neostigmine test for myasthenia gravis and consists of the injection of 1.5 mg. of neostigmine methylsulfate and 0.6 mg. of atropine sulfate per 150 lb. (68 kg.) of body weight. A positive result is judged clinically by an increase in the muscle strength and a clearing of the toxis.

IDIOPATHIC HEMOCHROMATOSIS

To THE EDITOR:—*In the person with idiopathic hemochromatosis what results may be expected from a determination of serum iron level and serum iron binding capacity? If these are normal, is further diagnostic work indicated, such as a liver biopsy or radioactive iron study? What is the best treatment?*

Marvin Garrell, M.D., Fairfield, Conn.

ANSWER.—The normal body weighing 70 kg. (155 lb.) contains 4 or 5 Gm. of iron. In idiopathic hemochromatosis there may be 25 to 50 Gm., and the serum iron level is usually elevated. Normally, the values are in the range of 100 to 150 mcg. per 100 cc. In idiopathic hemochromatosis the serum iron level may approach 300 mcg. per 100 cc.; but as the disease and the consequent liver damage progress, the plasma protein level may fall, and with it the serum iron level. Hence, more important than the serum iron level is the degree of saturation of the iron-binding globulin, transferrin (siderophylin). Normally this is only about 40% saturated, and while the normal serum iron level is 120 mcg. per 100 cc., the siderophylin can bind

300 to 400 mcg. per 100 cc. when it is completely saturated. In idiopathic hemochromatosis and transfusion hemosiderosis, the saturation of the iron-binding globulin approaches 100%.

If the serum iron level is normal and saturation of serum for iron is less than 50%, then hemochromatosis can be excluded and a liver biopsy is not necessary. It might be included as a diagnostic tool for other causes of cirrhosis. Radioactive iron is a research tool and was used to demonstrate that the defect in hemochromatosis is an increased absorption of iron from the gastrointestinal tract.

The best treatment for hemochromatosis depends on early diagnosis before liver damage has occurred, and then removal of the iron. For all practical purposes the excretion of iron is negligible, and to date the best method for the removal of iron has been repeated small phlebotomies, 250 to 500 cc. every three to six weeks. A 500-cc. phlebotomy removes 250 mg. of iron. The average diet contains 10 to 20 mg. of iron, of which less than 10% is normally absorbed. For this daily absorption of 1 or 2 mg., about 0.8 mg. is lost per day in desquamated cells, sweat, and urine; hence phlebotomy removes a significant amount of iron.

CHEMICAL BURNS OF RESPIRATORY TRACT

To the Editor:—*A 3-year-old boy ingested an indeterminate amount of ammonium thioglycolate (a home permanent neutralizer). Immediately after ingestion of it, the boy gagged, coughed, and vomited; he was cyanotic for three or four days. About two weeks later laryngoscopy revealed an inflammatory reaction of the larynx, trachea, and bronchi. About one year after ingestion of the poison he developed thinning and atrophy of the tongue. His voice is squeaky, and he has some hoarseness when he talks loudly. When he cries he sometimes has laryngeal stridor. What is the expected end-result of this scarring of the tongue and larynx?*

Howard Hansen, M.D., Baton Rouge, La.

Answer.—About a year ago, potassium bromate was being used as a neutralizer, but this was discontinued because of two or three reported deaths from the solution, and sodium perborate is now used as a neutralizer. The thioglycolate mentioned is found in the wave solution, but the caustic effect of this material has not been determined. The solution ingested caused a definite burn of the larynx and has apparently resulted in some laryngeal stenosis. It is unlikely that the thinning of the mucosa of the tongue would have any serious effect either in the immediate or distant future. It may be assumed that the patient had some loss of mucosa in the laryngeal area and as a result has obtained a fusion of the anterior commissure which has resulted in the high-pitched squeaky voice and hoarseness; it would also cause some stridor on breathing after unusual exertion. Since it has been one year since the accident, it is unlikely that the condition will progress beyond its present stage, and, as the child grows older, the size of the larynx would be expected to increase with his general growth, possibly not proportionately, but still sufficiently to allow him to avoid respiratory difficulty. The course of the condition should be followed with direct laryngoscopic visualization, first, to determine the exact condition of the larynx and, second, to have a standard for comparison in subsequent examinations.

MUSCLE REEDUCATION

To the Editor:—*I once attended a meeting at which Sister Kenny described her method of treating patients with paralytic poliomyelitis. She stressed the value of awareness or incentive on the part of the patient as the paralyzed muscles were passively put through their functional range of motion by the attendant after the hot packs had been used. She applied a special term, which I cannot recall, to this mental effort by the patient. Was this idea of conscious effort to move a paralyzed part during the passive exercise ever accepted by the medical profession?*

M.D., California.

Answer.—The Kenny method of muscle reeducation is divided into three phases. The first phase is tendon stimulation. This is an attempt to produce proprioceptive reflexes by passive motion of the joints normally moved by the affected muscles. It is done by several techniques, all of which involve stimulation of sensory proprioceptive endings to produce motor effects, and it is strictly a reflex action.

The second phase is restoration of mental awareness. This phase is probably the one mentioned in the question. In this technique the attempt is made to make the patient aware of the function of the muscle by using every type of sensory stimulation available. The normal motor pattern is reproduced by passive motion which involves proprioceptive stimuli. The skin is stroked over the insertion of the muscle to utilize tactile stimuli. The origin, insertion, and action of the muscle is described to the patient to provide auditory stimuli. The patient is allowed to watch the motion being performed passively to supply visual stimuli. All of these procedures are performed without the patient making any attempt at active motion. Fundamentally it is an attempt to reeducate the sensory side of the motor pattern.

The third phase is restoration of muscle function. At this time the patient first attempts to move the part voluntarily with assistance. Great care is taken to avoid substitution of other muscles in the motor pattern and to avoid tiring the patient during this reeducation process. As the patient develops more power and coordination he is allowed to do more for himself until he is able to perform the motion independently. This phase is an attempt to reeducate the motor side of the motor pattern. The technique is described more fully in the chapter Exercise in Poliomyelitis in "Therapeutic Exercise," volume 3 of the Physical Medicine Library, published by Elizabeth Licht, New Haven, Conn. It is used with some modifications in many poliomyelitis centers.

CHLORAMINES IN SWIMMING POOL

To the Editor:—*The water in a swimming pool is treated with chlorine soda ash and filtered through pressure sand filters. The pH of the water is maintained between 7.8 and 8.0, and the chlorine content varies from 0.8 to 1.0 ppm. When water is treated with chlorine, one of the by-products is nitrogen trichloride, an insoluble gas that tends to lay close to the water surface. This gas is irritating to the eyes of the varsity swimmers, who are taught to skim the surface, swimming with their eyes open. There have been no complaints from the womens' physical education class or other swimmers of the pool. Sufficient ventilation to remove this gas would be prohibitive not only in terms of cost of ventilation equipment but in terms of heating the air supply. What measures will prevent the eyes from burning due to exposure to this water?*

M.D., Nebraska.

Answer.—The analysis made of the reasons for the difficulties being experienced is not factual. In pool waters which contain ammonia, the addition of chlorine will cause the formation of chloramines. The particular chloramine depends on the pH of the pool water. At the pH level being maintained in this particular pool there is little likelihood that the trichloramine nitrogen trichloride will be formed. Trichloramine production would require a pH of about 4.5 to 5.0.

Studies on this problem indicate, however, that the monochloramines and dichloramines are eye irritants and may be responsible for the difficulties being experienced in this particular pool. Studies have indicated further that by the application of break-point chlorination, the chloramines can be eliminated with the formation of nitrogen and the oxides of nitrogen. This requires the maintenance of a pH of about 8.0 with a free residual chlorine of 2 to 3 ppm. A number of articles have been written on this subject. One article by Eric W. Mood appeared in the *American Journal of Public Health* (43:1258-1264 [Oct.] 1953). Mr. Mood has been highly successful in eliminating eye irritation among the varsity swimmers at Yale University by the application of this type of treatment to their pool water. Many others have confirmed his findings.

SPONTANEOUS ABORTION

To the Editor:—*Please comment on proper hospital routines for patients who have had a spontaneous abortion. What routine orders should be given to the nursing staff to prevent pelvic infection? May patients safely be placed in a room or ward with other patients with infectious diseases, such as pelvic inflammatory disease?*

M.D., Missouri.

Answer.—Most patients who have had a spontaneous abortion experience an uneventful afebrile convalescence, but it is not always possible to determine whether such persons have been subjected to manipulations to induce the abortion, with the increased likelihood of puerperal infection. A patient who has had an abortion should not be placed in the same room with a recently delivered mother nor should she be exposed to a gynecologic patient with subacute or acute pelvic inflammation. The patient who is febrile on admission, prior to the spontaneous abortion, or who develops fever should be isolated outside the clean maternity sections. She should be treated in the same way as a delivered mother who develops puerperal infection.

POSTHERPETIC PAIN

To the Editor:—*About five years ago, an 82-year-old woman, after an attack of herpes zoster at the level of the hemithorax and the right arm, developed a persistent pain in the right arm. At times her pains become so intense that she had to use ketobemidone for relief. The skin of the inner side of her arm and forearm is hypersensitive, wrinkled, and dry, and the hand has remained edematous for nearly two years, not permitting any movement of the fingers because of the pain. Roentgenograms of the hand showed ankylosis of practically all joints. Since the onset, sodium salicylate, piperazine, ACTH, cortisone, vitamin B_{12}, and procaine have been used but without relief. Can you suggest any treatment for this patient? What case fatality rate attends surgical treatment?*

Harry Kalenscher, M.D., Flushing, N. Y.

Answer.—Postherpetic pain is always difficult to treat and sometimes cannot be affected by any known treatment. In some patients it responds well to section of the peripheral nerve or relevant posterior nerve roots. In others, there has been some response to stilbamidine and large doses of vitamin B. The age of the patient in question seems to contraindicate radical surgery, yet local block of the thoracic nerve concerned may provide relief.

If regional block with procaine gives relief, one might consider a simple section of the thoracic nerve with the patient under local anesthesia. Sometimes such sections at the periphery cure or greatly ameliorate the pain. If this procedure fails, a posterior root section might be considered. The morbidity and mortality with such a procedure is low, although it would be somewhat higher in an elderly person. In competent hands, the procedure is short and may even be performed with the patient under local anesthesia, if general anesthesia is contraindicated.

SERUM AMYLASE

To the Editor:—*A patient has a consistently elevated serum amylase level (175 to 200 units per 100 ml.). The normal for the laboratory is up to 110. I am unable to find a cause for this. He complains of pain in the left parotid gland, which at times appears to be slightly enlarged, but he has not been febrile and has no manifest parotitis. Are there other causes of elevated serum amylase level besides inflammation of the pancreas and parotid gland?*

M.D., Illinois.

Answer.—Moderate elevations of serum amylase, that is, to levels from 200 to 700 units per 100 ml., may be found in such conditions as peptic ulcers penetrating or perforating into the pancreas, calculous obstruction of the salivary duct, renal insufficiency due to chronic or acute glomerulonephritis, chronic pancreatitis with a relapse involving previously unaffected tissue, and sometimes carcinoma of the pancreas. Apparently this patient has no renal insufficiency. Since he does complain of pain in the left parotid gland and shows occasional enlargement of this gland, the possibility of a small calculous obstruction of the salivary duct might be considered first.

SIMPLE CHRONIC ANEMIA

To the Editor:—*In reply to the question on simple chronic anemia, which appeared in* The Journal, *Sept. 13, 1958, page 227, the consultant stated, "The anemia will not respond to the administration of iron, vitamin B_{12}, folic acid, or any of the 'shotgun' antianemic preparations which, unfortunately, flood the pharmaceutical market." This appears to be an overstatement of facts. It may be asked on what basis the consultant concluded that none of these hematinics or a combination thereof would help the patient. In tropical countries, it is known that the iron taken in food often is not absorbed. Much of what is absorbed is excreted in the perspiration, and there are other nutritional deficiencies that are amenable to one or more of these hematinics or to a combination thereof, as in dimorphic anemias. Horrigan and co-workers* (Am. J. Med. 22:99, 1957) *found that in hyperferricemia none of the other hematinics helped until liver was given orally.*

K. S. Dharadhar, M.D.
P. O. Box No. 229
Bombay 1, India

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*The statement that none of these hematinics or a combination thereof would help the patient was based on the assumption, justified from the data provided, that if the patient had anemia at all it was of the simple chronic variety. This subject is beautifully discussed and documented, in terms of pathogenesis and treatment, by Wintrobe (Clinical Hematology, ed. 4, Philadelphia, Lea & Febiger, pp. 581-588). The original answer is entirely consistent with the views expressed by Wintrobe. The comment states that in tropical countries the iron taken in food often is not absorbed. Though this consultant has studied iron metabolism for years and is familiar with most of the literature on iron absorption, no studies have been seen that justify that statement. They would depend on careful balance studies or measurements with radioactive iron. If the commenting physician knows of such a published work, a reference to it would be appreciated. The question is hardy applicable to the specific case being discussed, however, since there was no evidence of iron deficiency.*

The comment further states that a lot of iron is excreted in the perspiration. Foy and Kondi offer evidence to indicate that there is a dermal loss of iron in the tropics from desquamation of epithelial cells (not in perspiration, per se), but even their work has not entirely eliminated iron contamination from the environment. Even if one accepts their work at face value, the fact remains that there is no evidence to indicate that persons with simple chronic anemia in the United States are iron-deficient or will respond to the administration of iron. The correspondent states that there are other nutritional deficiencies that are amenable to one or more of these agents or sometimes to a combination thereof as in dimorphic anemias. This is true, as Wintrobe also states, but the values given in the original inquiry would not be low enough for a dimorphic anemia. Even though one may have mild degrees of anemia in various nutritional disturbances, such as thiamine deficiency and pellagra, the use of a shotgun preparation is still not justified. The observations of Horrigan and co-workers are accepted without reservation. The situation must, however, be rare. This consultant knows of no cases other than those reported by him or to which he refers.
